During the past few weeks he had obtained definite statistics from the three Services, and he found that in the last three years the number of men invalided from the Air Force suffering from consumption was 92, from the Army 601, and from the Navy 479, giving an average of 390 per annum over the three Services. He found that the War Office had no records to show how many cases of the disease could be attributed to or aggravated by conditions of service. In the Navy 1·16 per cent. of the cases were held to be attributable to service and were granted pensions; in the Air Force 18·47 per cent. were held to be so attributable. He called the attention of the Committee to the remarkable difference between the figures for these two Services, and of the two he would think undoubtedly the Navy was the more unhealthy, because there there were men serving in submarines and torpedo boats, at times in very trying circumstances. He wondered whether the Air Force, being a junior Service, had perhaps not yet found out by tradition and precedent a rule of thumb for dealing with this matter. Perhaps they allowed a freer hand and had been a little more charitable to the men concerned. There must be some definite cause why apparently the Air Force medical officers were more sympathetic than those in the other Service. It was absolutely impossible in the majority of cases in either of the Services to define accurately whether the cause of the disease was attributable to the conditions of service, though one might have shrewd suspicions. That was not a sufficient ground for granting or refusing a pension. In all cases there was a very thorough examination, and a man who was found to have consumption was invalided out of the Service. But if it was found that the disease was not attributable to the conditions of service, the man could get nothing. He knew cases which went to show that under present conditions the amount of money which these men received as gratuity, and from the National Insurance Fund or the Services Fund, was grossly inadequate, and for the sake of their health and their lives it was necessary that some other means should be found of assisting them. Here there was a fund which could be partly applied to that purpose. He would suggest a scheme of compulsory insurance against consumption. If all the men paid 1*d.* per week it would provide each man invalided out of the Service with £100 capital. Out of the £1,100,000 with which the Committee was now dealing, a grant could be made of £250,000 to produce £10,000 a year, and taking the average of the cases of the last three years he reckoned that a sum of £10,000 a year would be sufficient to give these men £1 a week as long as they lived. He took it that the average period of life in those cases would be two years.

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) said that under the proposals of the Government a certain section of the men in whom Dr. Vernon Davies and other hon. Members were interested—the men who were unable to join the approved societies—would be able to receive much better benefits and assistance. As a result of the Government's proposals the cash benefits to these men would be increased in sickness to 18*s.* a week, to 9*s.* in respect of disablement benefit, and 40*s.* for maternity benefit—a very considerable increase. In addition they would receive, as recommended by the Royal Commission, the treatments which, on the average, were given, such as dental treatment, on the lines of the approved societies' additional benefits. The selection of these benefits would be made by the Minister of Health with the aid of the Committee which managed the Fund, and regulations would be laid before the House of Commons.

Mr. LLOYD GEORGE regretted that Sir Kingsley Wood had not found it possible to give a more sympathetic answer to the appeal which had been made by Dr. Vernon Davies.

Mr. Richardson's amendment was negatived by 227 votes to 141.

Clause 5 was added to the Bill by 229 votes to 121.

Clause 6 (which deals with consequential amendments of enactments relating to National Health Insurance and variation of reserve values) after discussion was added to the Bill by 225 votes to 132.

Clause 7 (short title and construction and application of Part I of the Bill) was agreed to by 210 votes to 128.

### MIDWIVES AND MATERNITY HOMES BILL.

This Bill, introduced by Colonel F. E. Fremantle and supported by the Government, to amend the Midwives Acts, 1902 and 1918, and to provide for the registration of maternity homes and other purposes, was considered by Standing Committee A of the House of Commons on Tuesday, April 20th, when Sir Kingsley Wood moved a drafting amendment to Clause 1, with the object of making it clear that there should be no possibility of admitting any man to the Midwives Roll. The Chairman ruled that if this amendment were passed it would cut out an amendment by Major Hills to substitute for "the personal supervision of a duly qualified medical practitioner" the words "in the presence of a duly qualified medical practitioner." Colonel Fremantle had a similar amendment to propose. Sir Kingsley Wood said he understood that the Central Midwives Board were now content with the clause as drafted, and his amendment was agreed to. An amendment to Clause 2, moved by Sir Kingsley Wood, to entitle a midwife suspended on account of infection to recover compensation from the local supervising authority, was agreed to. His further motion to leave out Clause 3 was negatived. An amendment by Sir D. Newton to make the councils of non-county boroughs and urban districts the authority to administer the Bill in their areas was discussed.

---

## HOUSE OF COMMONS.

### TUESDAY, APRIL 13TH.

### *Service Medical Organisation.*

Mr. HAYES asked the Secretary of State for Air what was the total cost of the headquarters medical organisation of the Royal Air Force; and whether he was taking steps to prevent overlapping between the Royal Air Force medical services and the medical services of the Navy and Army.—Sir S. HOARE replied: The answer to the first part of the question is £18,026, including clerical staff. As regards the second part, the fullest use is made wherever possible of naval and military hospitals for Air Force patients. There are only three separate Air Force hospitals in this country, and of these two are situated at stations at which large numbers of Air Force personnel are concentrated, but which are remote from any hospitals administered by the other Services; the third is a small hospital with only 25 beds, primarily intended for officers suffering from flying disabilities. Conversely the existence of Air Force hospitals in Iraq and Palestine eliminates the need for maintaining British or Indian Army hospitals for the imperial and local ground forces in those countries. To illustrate the extent to which effective coördination has been carried, I may say that during 1925 the admissions of personnel (including families) of the Royal Air Force to naval and military hospitals numbered 3227, whilst during the same period there were upwards of 8000 admissions of personnel of the Navy, the British and Indian Armies, and local forces in Iraq and Palestine to Air Force hospitals. The possibility of further coördination as between the Air Force medical service and the medical services of the Navy and Army (as well as the Ministry of Pensions) is kept continually under review by a Joint Medical Services Committee set up in accordance with the recommendations made by the Committee presided over by Sir A. Mond and announced in this House on May 30th, 1923. This Joint Committee advises in regard to: (1) important questions of medical policy such as the construction of new hospitals; (2) provision of facilities for common training; (3) specifications for the supply and medical stores and appliances; (4) the use of Navy, Army, and Air Force hospitals for the accommodation of disabled pensioners; (5) all matters in respect of which economies might be effected by coöperation of the four departments. Regular meetings have been held and the Committee has been successful in securing the closest coöperation and coördination of medical work in the three Services.

### THURSDAY, APRIL 15TH.

### *The University of London.*

Sir CYRIL COBB asked the President of the Board of Education whether the Government had arrived at a decision on the recommendations of the departmental committee on the University of London.—Lord E. PERCY replied: Yes, Sir. The Government are in general agreement with the committee's recommendations, and they propose to introduce legislation for the purpose of setting up a statutory commission for the university accordingly.

### *Slum Clearances.*

Mr. TREVELYAN THOMSON asked the Minister of Health how many local authorities had put in hand schemes for slum clearances under the Housing Act of 1919 and subsequent Acts.—Mr. N. CHAMBERLAIN replied: Since 1919, 78 local authorities have submitted schemes for dealing with slum areas, and I have information of 33 other local authorities who have schemes in preparation or under consideration. Eighty-five schemes relating to 67 local authorities have been confirmed.

### *Progress of Housing Schemes.*

Mr. TREVELYAN THOMSON asked the Minister of Health how many houses had been completed to date under the 1919 and subsequent Housing Acts and how many were at present under construction, giving separate figures for municipal and private enterprise.—Mr. N. CHAMBERLAIN replied: Up to the 1st instant 238,319 houses had been completed in England and Wales under the 1919 and subsequent Housing Acts by local authorities and 153,289 by private enterprise. The numbers under construction on the 1st instant were 45,920 by local authorities and 35,038 by private enterprise.

### *Deposit of Refuse in Rural Areas.*

Mr. RYE asked the Minister of Health whether he would consider the advisability of bringing in legislation which would strengthen the powers of local authorities in rural areas and enable them to prevent the deposit of refuse and other offensive matter in public places and so maintain local amenities.—Mr. N. CHAMBERLAIN replied: I am not satisfied, on present information, that further powers would be of any great practical advantage, but I am prepared to consider any further evidence that may be brought to my notice.

### *Miners' Welfare Fund and Hospital Grants.*

Mr. THOMAS WILLIAMS asked the Secretary for Mines how many grants had been made out of the Miners' Welfare Fund to assist in the erection of new hospitals or to extend existing hospitals; the districts where the grants were made; and the amount of such grants.—Colonel LANE FOX replied: Thirty-one allocations have been made out of the Miners' Welfare Fund to assist in the erection of hospitals or to extend existing hospitals in the districts of Fife, Northumberland, Durham, North Wales, West Yorkshire, South Derby, Warwickshire, Forest of Dean, and South Wales. The total amount of the allocations is £53,720. I am sending the hon. Member a detailed list of the schemes.

### MONDAY, APRIL 19TH.

### *Indian Medical Service.*

Colonel APPLIN asked the Under Secretary of State for India whether he was aware that officers of the Indian subordinate medical service who served with the Army throughout the war, and had since qualified in Great Britain in medicine and surgery, were debarred from entering the Indian Medical Service because their war service prevented them qualifying within the age limit; and if he would consider extending the age limit to 34 years in the case of medical officers who had been prevented from qualifying before reaching the age of 32 by reason of such war service.—Earl WINTERTON replied: Admission to the Indian Medical Service of members of the Indian Medical Department was one of the matters raised by the recent Anglo-Indian Deputation. My hon. and gallant friend's suggestion will be considered when the Government of India's views have been ascertained.

### *The Tuberculosis Order, 1925.*

Brigadier-General CLIFTON BROWN asked the Minister of Agriculture if he would state how many animals had been destroyed under the Tuberculosis Order of 1925; how much compensation had been paid on this account by the Government; and how much by the county rates.—Mr. GUINNESS replied: From Sept. 1st, 1925, when the Order came into operation, up to Dec. 31st last, 7151 cattle were slaughtered by local authorities and £31,294 paid by them in compensation. In accordance with the Diseases of Animals Act, 1925, £23,470 has been refunded by the Ministry, leaving the remaining quarter of the cost, or £7823, to be met out of local rates. I understand that the local authorities have also received £7958 by the salvage of carcasses, which more than covers their share of the compensation.

## Medical Diary.

*Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.*

### SOCIETIES.

ROYAL SOCIETY, Burlington House, Piccadilly, W.

THURSDAY, April 29th.—4.30 P.M., *The following papers will be read:* C. H. Best, H. H. Dale, J. P. Hoet, and H. P. Marks: Oxidation and Storage of Glucose under the Action of Insulin. C. H. Best, J. P. Hoet, and H. P. Marks: The Fate of the Sugar Disappearing under the Action of Insulin. (Communicated by Dr. H. H. Dale.) J. P. Hoet and H. P. Marks: Observations on the Onset of Rigor Mortis. (Communicated by Dr. H. H. Dale.) J. C. Mottram, G. M. Scott, and S. Russ: On the Effects of Beta Rays from Radium upon Division and Growth of Cancer Cells. (Communicated by Prof. A. W. Porter.)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, April 26th.—8 P.M., ODONTOLOGY. Mr. W. Warwick James: Do Epithelial Odontomes Increase in Size by their own Tension? Dr. E. W. Fish: The Circulation of Lymph in Dentine, with some Observations on the Metabolism of this Tissue.

TUESDAY.—5.30 P.M., MEDICINE. Discussion: The Clinical Significance of the Respiratory Metabolic Rate. Opener: Dr. E. P. Poulton, followed by Dr. C. M. Wilson, Dr. Gardiner-Hill, Dr. R. D. Lawrence, Dr. Reginald Hilton.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos-street, Cavendish-square, W.

FRIDAY, April 30th.—8.30 P.M., Papers will be read by Dr. Lacapere, of Paris, and Dr. R. C. Jewesbury, on Marriage and Syphilis. A discussion will follow.

SOCIETY OF SUPERINTENDENTS OF TUBERCULOSIS INSTITUTIONS.

MONDAY, April 26th.—3 P.M. (at 122, Harley-street), Dr. F. R. Walters: Some Needs and Indications for Treatment in Pulmonary Tuberculosis. Dr. F. A. Lucas Hammond: Phthisical Psychosis. Dr. S. Woodhouse: The Pathology of Pleural Adhesions in Tuberculosis.

### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, April 26th, to SATURDAY, May 1st.—Special afternoon demonstration in clinical surgery on Tuesday at 2 P.M., at the Royal Northern Hospital, by Mr. Gwynne Williams.—ROYAL FREE HOSPITAL, Gray's Inn-road, W.C. Wednesday, at 5.15 P.M., Dr. Heald will demonstrate the Medicinal Uses of Ultra-Violet Light.—ST. PETER'S HOSPITAL, Henrietta-street, W.C. Clinical work each afternoon and special lectures. Further information from the Secretary of the Fellowship of Medicine.

ANCOATS HOSPITAL POST-GRADUATE LECTURES, Quay-street.

THURSDAY, April 29th.—4.15 P.M., Mr. McEvedy and Dr. Twining: The Surgical Dyspepsias.

MANCHESTER AND SALFORD HOSPITAL FOR SKIN DISEASES POST-GRADUATE COURSE.

THURSDAY, April 29th.—4.30 P.M., Dr. Stavely Dick: Uses and Abuses of Laboratory Methods in the Diagnosis of Syphilis.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, April 27th.—4.15 P.M., Mr. S. R. Wilson: The Evolution of Anæsthetics.

FRIDAY.—4.15 P.M., Dr. A. E. Barclay: X Ray Investigation of the Intestinal Tract.

## Appointments.

CADDY, A., M.D. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Royal Westminster Ophthalmic Hospital and Ophthalmic Surgeon to the Woking and District Victoria Hospital.

EVANS, T. B., M.B., Ch.B. Liverp., Medical Officer of Health, Abersoch, S. Carnarvonshire.

HALL, ARTHUR, M.D. Camb., F.R.C.P. Lond., Consulting Physician to the South Yorkshire Mental Hospital, Sheffield.

SOLLY, E., M.B. Lond., F.R.C.S. Eng., a Medical Referee under the Workmen's Compensation Act for Bradford, &c. (Circuit No. 12).

STURROCK, Eva M., M.B., Ch.B. Glasg., D.P.H., Assistant Medical Officer of Health, Burgh of Motherwell and Wishan.

Wrexham and East Denbighshire Hospital: DAVIES, A. L., M.B., Ch.B. Liverp., WALWYN, F., L.R.C.P & S. Edin., REID, J., M.B., Ch.B. Edin., Hon Asst. Physicians and Surgeons; WILSON, M.B., Ch.B. Dub., Hon. Ophthalmic Surgeon; GRACE, W. H., M.D. Lond., Hon. Pathologist; WALLIS, R., Hon. Dental Surgeon.

## Vacancies.

*For further information refer to the advertisement columns.*

*Beit Memorial Fellowships for Medical Research.*—Jun. Fellows. £350.

*Bristol Royal Hospital for Sick Children and Women.*—H.S. £125.

*Bristol University.*—Lecturer in Forensic Medicine and Toxicology. Also Lecturer in Public Health.

*Burton-on-Trent Infirmary.*—Jun. Res. H.S. £150.

*Cancer Hospital, Fulham-road, S.W.*—H.S. At rate of £100.

*Coventry and Warwickshire Hospital, Coventry.*—Res. H.S. £150. Res. H.P. £125.

*Dagenham Sanatorium, Dagenham, Essex.*—Asst. M.O. £250.

*Durham County Mental Hospital.*—Second Asst. M.O. £500.

*Greenwich, Dreadnought Hospital.*—Med. Supt. £300.

*Hampstead General and North-West London Hospital, Haverstock Hill, N.W.*—H.S. and Cas. Surg. O. Each at rate of £100.

*Hospital for Epilepsy and Paralysis, Maida Vale, W.*—Med. Reg. £100.

*Leicester Royal Infirmary.*—H.P. At rate of £120.

*Liverpool, Eye and Ear Infirmary, Myrtle-street.*—Hon. Aural S.

*London Hospital, E.*—Asst. in Dept. of Dermatology and Syphilology.

*Metropolitan Asylums Board, Mental Hospitals Service.*—Second Asst. M.O. £560. Also Jun. Asst. M.O. £500.

*Plymouth Borough.*—Asst. Port M.O., &c. £750.

*Preston and County of Lancaster Royal Infirmary.*—Hon. Surg. to Eye, Ear, Nose and Throat Dept. Also Hon. Asst. S.

*Prison Medical Service.*—M.O. £350.

*Richmond, Surrey Royal Hospital.*—H.S. and Asst. H.S. £150 and £100 respectively. Also Hon. P. to Out-patients.

*Royal College of Surgeons in Ireland.*—Prof. of Physiology.

*Royal Northern Hospital, Holloway.*—Surg. and Phys.

*St. Mary's Hospital, W*—First Asst. Pathologist. £500.
*Salisbury General Infirmary*—H.S. £150
*Sheffield Royal Infirmary*—Jun. Aural and Ophthalmic H.S. £80
*Surrey County Council, Kingston-on-Thames.*—Asst. M O. £600
*University College Hospital, Gower-street, W C*—Harker Smith Reg £350 Also Obstetric Reg £125
*Wigan Infirmary*—Third H.S. £150

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Biggar (Lanarkshire).

The Secretary of State for the Home Department announces a vacancy for a Medical Referee under the Workmen's Compensation Act for the Kilmarnock District (Sheriffdom of Ayr) Applications should reach the Private Secretary, Scottish Office, not later than May 12th.

A vacancy for a Medical Referee under the Workmen's Compensation Acts (Northern Ireland) for the County of Down is announced. Application should be made to the Secretary, Ministry of Labour, 7, Upper Queen-street, Belfast, not later than May 8th.

A vacancy for a special appointment of a Medical Practitioner under the Workmen's Compensation Act, 1906, for cases arising in mines in the district of Ashton-in Makerfield is announced. Applications for the post or for further information should reach the Private Secretary, Home Office, Whitehall, London, S W 1, not later than May 15th.

# Births, Marriages, and Deaths.

## BIRTHS.

ATKIN—On April 12th, at The Glen, Sheffield, the wife of C. S Atkin, M B, of a son

GURNEY DIXON—On April 14th, at Ober House, Brockenhurst, Hants, the wife of S. Gurney Dixon, J P, M.D, of a daughter

MASON—On April 15th, at Great Portland-street, W, the wife of Dr C L. Mason of a daughter

## MARRIAGES

BICKERTON—HAWDON—On April 10th, at St. Cuthbert's Church, Ormesby, Yorkshire, by the Ven. Archdeacon Lindsay, assisted by the Vicar, the Rev. J O. C. Kemm, John Myles Bickerton, F R.C.S, youngest son of Mr and Mrs. T. H Bickerton, of Liverpool, to Margaret Alsager, only daughter of Colonel and Mrs. Hawdon, Upsall Grange, Nunthorpe, Yorkshire.

BOYLE—RUANE.—On April 14th, at SS Peter and Paul Church, Ilford, Captain H A Boyle, R.A.M.C., to Mary Ellen Ruane, eldest daughter of Mrs. Catherine Ruane, of Ilford, Essex.

VON BRAUN—COLE HAMILTON—On April 15th, at the British Embassy Church, Paris, C R. B von Braun, M.R.C.S., L.R.C.P., late Captain, R.A.M C, to Nora Kathleen, only daughter of Major W M Cole-Hamilton, Beltrim Castle, Co Tyrone

GIMLETTE—WILSON—On April 14th, at St. Jude's Southsea, Captain G. T Gimlette, R.A.M.C., to Mary, younger daughter of Mr and Mrs. A. Wilson, Southsea.

HUSBANDS—FIELD—On April 14th, at All Souls', South Hampstead, Roland Husbands, M.B., B.S. Lond., to Dorothy, younger daughter of the late A. J Field, of Bushey, and Mrs. Field of Oxhey, Herts.

McKINLAY—ALEXANDER.—On April 17th, at the Parish Church, Walton-on Thames, Captain R. McKinlay, to Audrey Forbes, elder daughter of Dr Forbes Alexander and the late Mrs. Forbes Alexander, Clevedon, Weybridge.

SHERWELL—WILKINSON—On April 10th, at St. Saviour's, Torquay Arthur Erskine Sherwell, M.B, Ch.B, to Mary Eileen Grace Wilkinson, L.S.A., eldest daughter of Dr and Mrs. T B Wilkinson, of Plymouth.

## DEATHS.

BOTT—On April 14th, at Washenden Manor, Biddenden, Kent, Henry Bott, M.R.C.S., L.R.C.P., late of Brentford, aged 72 years.

BOUCH.—On Tuesday, April 13th, Thomas Bouch, of 45, North cote-avenue, Ealing.

SMITH—On April 13th, at Richmond House, Ingleton, Carnforth, Yorks, John William Smith, D L, F R.C.S., Brev Col., R.A.M C (Territorial Force), late of Manchester, aged 61.

*N.B—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths*

ENLARGEMENT OF CHARING CROSS HOSPITAL.—The Royal Westminster Ophthalmic Hospital has been purchased for the enlargement of Charing Cross Hospital, which it adjoins, but it is expected that two years will elapse before the building is available Both institutions are in need of enlargement, but until now neither could expand save by removal, and even as it is the cost of buying and converting the ophthalmic building is estimated at £100,000 It is intended to use it for heart cases and ear, nose and throat patients. The Ophthalmic Hospital has acquired a site in Broad-street, Bloomsbury, large enough for the erection of "the largest and finest ophthalmic hospital in London."

# Notes, Comments, and Abstracts.

## HEALING SAINTS.

THE amusing communication from Sir Wilmot Herringham on hagiological therapeutics (THE LANCET, March 13th, p 574) has stimulated a correspondent to send us the following note on an interesting statuary group of healing saints in Brittany He writes :—

"Perched on its rocky hill between two deep glens stands old grey Montcontour in Brittany. Before the days of the light railway the small town was one of the most primitive in an old-world countryside, for there the bare-footed peasant women still used the distaff and the coach-horses were led over the earthen floor of the inn kitchen into the stable beyond. Rudimentary beliefs die hard in such surroundings, and it is probable that even to-day the peasants of the district still offer prayer to the *saints guérisseurs* in the chapel of Notre Dame du Haut, about a mile away from Montcontour. These renowned saints are six in number and are represented by expressive images of fifteenth-century date. St. Lubin, to the right of the row of statues, is a bishop in full canonicals. His face is beatific in expression and he raises one hand in act to bless. He is invoked by the sick in all kinds of illness. Next to him is the tall figure of St. Mamert, whose office it is to cure diseases of the intestines. He is in a monkish habit and his abdomen, in appearance like a large flat oval loaf, is displayed outside his robe. He clasps this with his two hands, and his face expresses suffering A bishop with crozier and open mass book directly on his left is St. Méen, patron of the demented Then comes a little dapper huntsman armed with a spear and reminiscent of Chaucer's Canterbury Pilgrims. This is St. Hubert, who is good against dog bite, especially in cases of hydrophobia. St Livertin, fifth in the row, is a tall priest. He is invoked by those who suffer from headache, and his functions are well expressed by his finger-tips, which are laid to his temples. The pose suggests facial neuralgia, and this is probably the ailment most in vogue among a hardy people not otherwise worried by head troubles. Most curious of all this sextet is the last saint in the row This is St. Honarniole, who guards against fear. The sufferer from phobias of various kinds prays to him, and he wears a reassuring expression and appears to be walking cautiously forward supported by two long staves, one in each hand His long hair, beard, and dress suggest the layman, and his name indicates a purely local celebrity."

With reference to the exact connexion between the healing saints of early Christianity and mediæval days and the healing divinities of the classical era our correspondent writes: "That healing saints are certainly traceable to a pagan original was well shown by the late Prof. Tylor in his 'Primitive Culture.' In the chapters on Animism he cites two prime instances of this process of transition. Thus St. Theodorus has apparently succeeded Romulus as the patron of sickly infants, his church occupying the site of the little round temple at the foot of the Palatine, whither the mothers of ancient Rome brought their children to be presented to the founder of the city, who had been deified as propitious to their health and safety. In his famous 'Letter from Rome,' whose sceptical tendencies got him into trouble, Conyers Middleton, Bentley's bitter adversary, describes how he used to look in at the church of St. Theodorus and see groups of women, each with a sick child in her lap, sitting in silent reverence before the altar of the saint. The ceremony of blessing children, especially after vaccination, may still be seen there on Thursday mornings. SS. Cosmas and Damianus are generally acknowledged to owe their recognised office as healing saints, and especially of plague, to a similar train of events. They were martyrs who suffered under Diocletian at *Aegeae in Cilicia.* Now this place was one of those particularly celebrated for the worship of Æsculapius, in whose temple incubation—i.e., sleeping for oracular dreams—was practised. 'It seems,' writes Tylor, 'as though the idea was transferred on the spot to the two local saints, for we next hear of them appearing in a dream to the Emperor Justinian when he was ill at Byzantium. They cured him, he built them a temple, their cultus spread far and wide, and they frequently appeared to the sick to show them what they should do' SS. Cosmas and Damianus were thus manifest descendants of the old Asclepiades. According to legend they had been physicians before their martyrdom, and they became the patron saints of the profession of medicine."

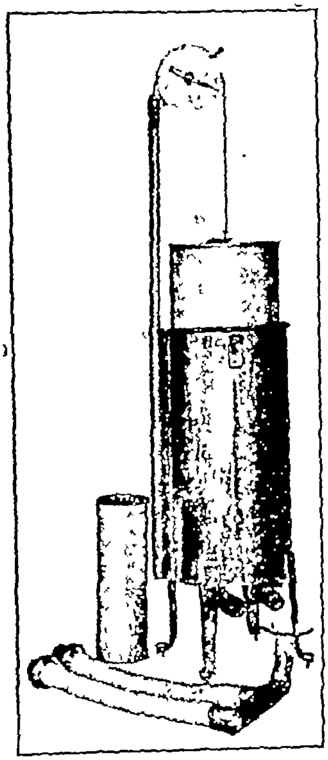
## AUSTRALIAN HOSPITALS.

THE growing pressure upon hospitals which is creating so difficult a problem at home is being experienced also in the Commonwealth. The report of the Public Health and Hospitals Department of Western Australia for 1923 and 1924, which has just reached us, shows that during that period in the larger hospitals, especially that at Perth, the increased demands upon accommodation have reached serious dimensions. In the country districts, some of which have no hospital provision, the need has become so great that 18 new hospitals have been opened. There are three public hospitals in the State with an average of 520 beds occupied in 1924, an increase of nearly 20 per cent. since 1921. The average of 81 occupied beds in the 37 assisted hospitals shows an even larger growth. The same tendency is noticeable in the 24 Government hospitals, the number of patients treated having been 5900 in 1924 as compared with 3877 in 1922. We note that the daily cost per patient in these hospitals was 9s. 4½d., which is a reduction on previous years. The death-rate of Western Australia in 1923 was 8·41, a "record" for the Commonwealth.

The report of the *Royal Prince Alfred Hospital, Sydney*, for the year ending June 30th, 1925, shows that 7740 patients were admitted, and that their mean residence was 24 days. In the out-patient and casualty departments 47,000 persons were treated. The work of the pathological department greatly increased, and there was also a large increase in the use of insulin. The whole question of the treatment of tuberculosis in the Sydney hospitals is under consideration, and it appears to be probable that a central bureau will be established for the better coördination and direction of the work throughout New South Wales. Owing to the change in the medical curriculum, which now extends over six years, and a falling off in the number of students entering the medical school, the number of students attending the hospital was only about half that of the previous year.

## ESTIMATION OF BASAL METABOLIC RATE.

THE estimation of basal metabolism by the British "Benedict" portable metabolism apparatus is a *closed circuit* method in which the oxygen consumption is measured directly. Its simplicity, rapidity, and accuracy are causing it largely to supersede, at least for clinical purposes, the standard *open circuit* method of employing the Douglas bag and gas analysis. The latter, although the choice for really exact scientific work, is too time-consuming and laborious for ordinary routine at the bedside. And further, unless the operator is specially skilled and exceedingly careful wrong results are apt to be obtained, and perhaps not infrequently results very far wide of the mark. The technique required for the method is less involved and laboratory assistance is unnecessary, but, nevertheless, the same careful attention to details must be observed. The apparatus is conveniently portable, and as regards accuracy, the all-important point, it has been shown that in competent hands results are obtained that compare well with those of the Douglas bag method.



The apparatus illustrated consists of a spirometer cylinder (6½ litres capacity), balanced by a weight-and-pulley arrangement suspended over a double-walled cylinder, and dipping into a water-seal between the vertical walls. The spirometer is filled with oxygen and the patient inhales from, and exhales into, this enclosed circuit through two breathing tubes provided with inlet and outlet valves. Within the inner cylinder is a container of soda-lime (calsoda) which removes all the carbon dioxide. Therefore, the difference between the readings taken on the self-registering dial of the pulley-wheel at the beginning and end of the test gives the amount of oxygen consumed. Corrections are made for temperature and pressure, and a comparison with figures for normal persons of the same weight, height, and age shows whether the metabolic rate is up or down. Three or four 4–7 minute tests are generally required, and since gas analysis and other laboratory determinations are unnecessary, results can be had a few minutes after finishing the tests. Two modifications in this apparatus on its immediate predecessor —the "Handy" Sanborn, described and recommended by Mr. T. C. Hunt in THE LANCET of Jan. 23rd (p. 172)—should be favourably mentioned: (1) the introduction of inlet and outlet valves prevents any re-breathing of $CO_2$; (2) the inertia of the spirometer cylinder is practically eliminated by the counterpoise pulley arrangement.

Considerable experience with the method has shown that in addition to the ordinary care in technique special attention should be directed to the following points, as it is here that error is most liable to creep in: (1) The entire apparatus should be thoroughly tested for leaks. (2) The spirometer cylinder must be accurately balanced by means of the four levelling screws and the pulley counter-weight. (3) The most vital part of the apparatus is the carbon dioxide absorber, and it demands systematic examination, say, once or twice a week, or oftener if needed. The capacity of the calsoda to absorb $CO_2$ should be tested for by filling the spirometer-bell with expired air, plugging the mouth-piece and causing the contents to pass out via the oxygen inlet-tap and bubble through lime-water. If the calsoda is all right no cloudiness will occur. (4) It is essential that the readings at the beginning and end of a test are taken in the course of periods of steady regular fall in the volume, as shown by the hand on the dial. For this purpose a stop-watch is of great service, as readings may then be taken at any fraction of a minute when the breathing is satisfactory and accurate calculations made.

The British "Benedict" apparatus is sold by Herbert E. Kendrick, 342, St. John-street, London, E.C. 1.

## VOCAL THERAPY FOR DISABLED MEN.

AMONG the various organisations for bringing help to the minds and bodies of the men still disabled after the war, the Vocal Therapy Society, whose report for 1924–25 is to hand, plays a modest but nevertheless a decidedly useful part. The report states that its aims are: "1. To promote through speech, song, and efficient breathing the physical and mental health of sick, wounded, and disabled sailors, soldiers, and airmen in hospitals and centres of discharged men. 2. To adopt under medical advice the most effective methods of individual and class training in singing, speaking, and breathing. 3. To select voluntary and paid teachers with the necessary high qualifications. 4. In furtherance of these aims to form the hospital and other ex-Service singers into choirs." The beneficial results of correct instruction in breathing and voice-production are undoubted in those suffering from speech-defects, injuries of the jaws, and paralyses; but, apart from these more obvious cases, many of the chronically disabled patients are awkward, self-conscious, and miserable. It appears from the report, as would be expected, that the singing and dancing classes have given such patients an interest, relieved their shyness, and improved their morale. The society has a number of distinguished musicians and medical men upon its committee, and employs half a dozen teachers; it cannot afford more, and its activities have had to be curtailed owing to decreasing funds. But there are still, unfortunately, many thousands of disabled men, and we commend this society to the interest of the philanthropic.

## *THE NORTH-WESTERN NATURALIST.*

WE heartily congratulate Mr. A. A. Dallman on the first number of this successor to the *Lancashire Naturalist* which has recently appeared under his editorship. There is evidently no dearth of good material in Lancashire, Cheshire, North Wales, and the neighbouring parts, and the activity of the workers will reciprocate with an adequate publication of their results to promote one of the most humane of human interests in which medical men have always taken a leading part. The number contains a sympathetic notice of the late Dr. H. Drinkwater, who filled up the spaces in a distinguished career as a doctor at Wrexham with notable contributions to botany, medical biography, and Mendelian heredity. Prof. A. E. Boycott has a short article on a unicellular alga apparently parasitic in a water-snail, and there are many notes of biological and antiquarian interest. If the present standard can be maintained we do not doubt the success of the new venture. The most substantial paper is a survey, along ecological lines, of the daddy-long-legs of Carnarvonshire by Mr. H. F. Barnes.

## *"C.P."*

WE have been used to this abbreviation for many years in this country as signifying Clerk of the Peace, Common Pleas, Court of Probate, and last, but not least, Carter Paterson and Carriage Paid, and in technical circles as Chemically Pure. We now see that C.P. in the United States is to stand for "Council Passed," meaning, when affixed to a chemical product, that it has been approved by the Council on Pharmacy and Chemistry of the American Medical Association, and accepted by them for inclusion in new and non-official remedies.

# An Address
ON
# VISCERAL PAIN AND REFERRED PAIN.

*Delivered before the Oxford Medical Society on Feb. 12th, 1926,*

BY J. A. RYLE, M.D., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN AND LECTURER ON MEDICAL PATHOLOGY, GUY'S HOSPITAL.

THERE are problems in medicine which make a general appeal, and others of a more special character which cannot equally attract all minds. In choosing for discussion certain aspects of pain, I have hoped at least to avoid the imputation of specialism, for it would be difficult to conceive of a problem more universal and more appropriate to our art. Whether our inclinations be medical or surgical, or our thoughts cast in a physiological or an anatomical mould; whether our work be academic or more severely practical, there are features of the problem which can hardly fail to claim attention. To seek out the causes, to assess the consequences, and to encompass the relief of pains is for most of us a daily duty. Familiarity cannot—or should not—deprive the subject of its fascination or blind us to its difficulties.

If there is a fault in us bred of familiarity it is, I believe, the old fault of omitting to probe sufficiently deeply into causes; the fault of accepting the fact of common symptoms without explaining them. For this reason my remarks will be confined to a review of the present state of our knowledge of the nature and causes of some more familiar types of pain. Research into the subject does not commend itself to the experimentalist in the laboratory, for subjective phenomena are difficult to pursue in animals, and the varieties of pain which can be reproduced and studied in the healthy human being are of necessity limited. On the other hand, those who are engaged in the practice of medicine or surgery, and have the most frequent opportunities of observing the experiments in pain with which nature herself provides us, are usually so harassed by the exigencies of work that ordered observations are hard to accumulate and still more hard to analyse. Furthermore, the experiments often take months or years to march to their conclusion, and only too frequently they are not concluded at all. I think, however, it may fairly be urged that we owe—as we should do—our most valuable information relating to the mechanism and distribution of pains to the clinicians, and that it should rest with them to direct inquiries in the future, employing ever more careful method, and seeking scientific coöperation whenever possible. With the work of such men as John Hilton, Sir James Mackenzie, and Henry Head to reflect upon we do not lack for inspiration in this country.

It is with some diffidence that I approach the subject of local pain and referred pain in visceral disease, for if the more superficial pains are difficult to elucidate the deeply seated pains are more so. Moreover, the ground which must be covered is wide and beset with controversies. I shall confine myself to a consideration of pain associated with disease of the hollow viscera, for it is doubtful whether the solid viscera are possessed of any sensibility. My argument will be mainly clinical, and I must pray the physiologists and anatomists for leniency whenever my remarks seem to lack that precision which their more ordered sciences demand.

### THE MECHANISM OF VISCERAL PAIN.

To begin with, let me recall that there have been two main schools of thought in regard to the mechanism of a visceral pain. The first school, basing its views on the work of Lennander[1] and having the late Sir James Mackenzie[2] as its most vigorous protagonist, concludes that pain is not felt in the viscera, but that it is referred to the somatic tissues supplied by the same segment of the cord which supplies the viscus in question. The latest edition of a well-known physiology text-book still perpetuates this view. The second school, supported by Ross[3] and Hurst[4] and perhaps the majority of physicians, while recognising that visceral disease may be accompanied by referred somatic pain, contends that the viscera themselves are capable of feeling pain in the presence of appropriate stimuli.

I shall endeavour to support the following hypotheses:—

1. That there is a true visceral pain felt by the viscus.

2. That visceral pain is due to an abnormal increase in the tension of the muscular element of the wall of the viscus, this increased tension resulting either from contraction or from a failure on the part of the muscle-fibre to relax adequately in the presence of increased intravisceral pressures.

3. That visceral pain when occurring alone, or dissociable from attendant somatic pains, may be accurately localised by the patient.

4. That referred somatic pain and tenderness—e.g., the viscero-sensory reflexes—and the associated viscero-motor reflexes, although they may accompany a severe visceral crisis of mechanical origin, more frequently express an inflammatory lesion of the viscus.

5. That, when persistent, they invariably express organic disease of the viscus of an inflammatory kind.

I shall illustrate my remarks by referring to painful disorders of the stomach, the gall-bladder, the appendix, the intestine, the kidney and ureter, the uterus and Fallopian tubes, and, finally, of the heart and arteries, but I would first draw your attention to certain general considerations.

### *Normal Sensibility of Hollow Organs.*

If it be claimed that visceral pain is not produced in the viscus it seems pertinent to inquire where the normal sensations peculiar to certain viscera are felt. I have never seen it suggested that these normal sensations are referred to the somatic tissues, nor does daily experience suggest that they are felt elsewhere than in the viscus. The heart and aorta, excepting for the sensations of præcordial fullness and retrosternal oppression experienced during violent effort or emotion, may be said to be insensitive under physiological conditions. In the case of the stomach we recognise the gastric elements of the appetite and hunger sensations, and the sensations of fullness or repletion. These have been clearly related with the tonic and peristaltic activity of the stomach wall, and the work of Carlson[5] and Hurst[4] would seem to indicate that the sensations depend on the state of tension in the gastric muscle-fibre. Of the appendix and gall-bladder we are quite unaware in health. Of the intestine we are aware whenever local distension with flatus occurs. The rectum clearly appreciates states of fullness, at times of urgency amounting to pain, and most of us would agree that its sensations are deeply and not superficially situated. The sensation of the desire to micturate is felt in the urethra and in the bladder also when it is over-distended. All these physiological sensations are related to increasing pressure on the walls of the viscus and are relieved by evacuation. Menstrual pains are felt locally, but are frequently accompanied by a more superficial sacral pain. It is, however, worthy of note that a state of congestion akin to the effects of inflammation is present in this condition in addition to increased muscle tension, and that no equivalent congestion is present during the normal functional activity of other hollow viscera.

Lennander[1] showed that the abdominal viscera when exposed could be pricked, pinched, cut, or burnt without causing pain, and we are all familiar with the insensibility to these stimuli of a colotomy loop. Waugh[6] has recently shown a similar insensibility in the case of the heart. It is further obvious that the gastric and intestinal mucosa have no tactile and very little thermal sensibility, for if they had, we should be far more conscious of ingested foods and fluids, of enemata, and of the normal processes of digestion. Hurst[4] and his collaborators demonstrated by experiment the insensibility of the gastric and rectal mucosa to tactile, thermal, and chemical stimuli, and Hilton[7] long ago remarked on the insensibility of the rectal as compared with the anal mucosa. These observations support the contention that, if the hollow viscera are sensitive, it is not their serous or mucous coats but their muscular coats which appreciate the sensations. Those who contend that the viscera are insensitive seem to have paid too little regard to the fact that special organs respond only to special stimuli. Thus the eye appreciates light and not sound; the skin appreciates touch, temperature, and traumatic pains, all of which it is physiologically essential for it to appreciate; the skeletal muscles appreciate position and tension and the strength of opposing forces and (in states of extreme tension) pain, but they are not, I believe, sensitive to cutting, pricking, or burning. There is no reason for the viscera to appreciate tactile or thermal stimuli, but it is vitally necessary for them to appreciate states of fullness and emptiness. By analogy it seems reasonable to insist that the plain muscle of the hollow viscera is endowed with the same sensibility, positive and negative, as the skeletal muscles; in other words, that *visceral sense is muscle-sense.* The sensations of fullness or emptiness are thus parallel with the sensations of posture and tension in a limb. Pain (whether in skeletal or plain muscle) results when tension is greatly exaggerated in one manner or another. The one common factor present in all cases of visceral pain is an increase in intravisceral pressure and in muscular tension. The relieving factor, whether it be the passage of a gallstone in biliary colic, the ingestion of food in hunger pain, or the peripheral vaso-dilatation on administration of amyl nitrite in angina pectoris, is invariably a factor which reduces intravisceral pressure.

What further evidence have we that visceral pain is deeply felt and not somatic? It will be agreed that ordinary stomach-ache and intestinal colic give the impression of being felt internally. Those who have experienced severe visceral pains of mechanical origin, such as renal and biliary colic, are agreed that these sensations seem to be deep to the body wall. I think it is also true that the majority of non-inflammatory visceral pains (unless they fall into the group of the severe visceral crises) are but rarely accompanied by reflected superficial pain or soreness, and in the case of inflammatory lesions we may observe, as I shall show, referred somatic pain or tenderness occurring in the absence of local visceral pain, and thus suggesting that the causal processes are not identical.

Guarded though we should be in accepting the observations of our patients as accurate evidence, we must, nevertheless, attach importance to certain "gestures" which they employ in indicating the seat of their pain. These gestures do not, as a rule, apply to a somatic segment, but to the surface-marking of the viscus. Thus, in describing anginal pain the patient places his clenched hand to the sternum as though to indicate a median or aortic origin for his pain, and, perhaps, incidentally, to imply its gripping character. A cardiac pain, on the other hand, is indicated by applying the flat of the hand to the submammary region. The pain of gastric ulcer is indicated with the tips of two or three fingers applied to the mid-epigastric point or occasionally just to the left of this point; the pain of duodenal ulcer by a similar demonstration frequently just to the right of the mid-line. The gesture of renal colic is made familiar by the pictorial advertisements of a certain proprietary back-ache pill; the hand grasps the loin usually with the fingers over the back and thumb in front, as though to imply that the pain requiring subjection is rather more posterior than anterior and deeply situated in the actual position which the kidney occupies. The localisation of pain in gall-bladder and appendicular disease (when there is no confusion due to associated inflammation or gastric and intestinal disturbance) is remarkably accurate. The position of a calculus impacted in the ureter may also be accurately shown when distraction by concurrent renal colic or other symptoms is not too influential. Intestinal pains are less easily localised, but here the actual position of the painful contraction is variable, for intestinal colic is not confined to one spot as is the case with biliary or renal colic. Small intestine pains are usually felt around the navel, and colonic pains between the navel and the symphysis pubis. When, however, obstruction occurs at a more or less fixed point such as the hepatic, splenic, or sigmoid flexures, then the localisation is commonly precise. One of the most recent text-books of physiology, in the very brief references to this subject which it makes, asserts that visceral pain is vaguely and inconstantly localised. I believe that clinical experience teaches otherwise, if only we are careful to dissociate the primary or local from the secondary and referred phenomena.

It will be conceded that the reflected phenomena of visceral disease are best demonstrated in association with the very severe forms of visceral pain or in association with inflammatory disease. The arm pain of angina, the subscapular pain of cholelithiasis, and the testicular pain in ureteric colic are the classical examples of the former group; of the latter the cutaneous hyperalgesia and muscular guarding found in appendicitis or in relation to a chronic gastric ulcer are the best examples. It is worthy of note that these reflected phenomena rarely accompany visceral disease of a functional kind; in other words, that they are generally associated with local organic changes. In the majority of fatal cases of angina pectoris there is found some disease of the first part of the aorta or coronary vessels, and we know that, although the sensation of retrosternal oppression can be reproduced in health by vigorous exercise upon a frosty morning, the arm pain is not so reproduced and, since the vessels are capable of relaxation, local distress is never agonising. In stomach-ache due to extragastric causes I have not found cutaneous soreness or muscular guarding. With the subscapular pains of gall-stones it may be pleaded that the pain is as much an effect of the cholecystitis as of the stones; certainly, an *identical subscapular pain occurs* in cholecystitis without gall-stones. In the testicular pain of calculous ureteric colic the ureteric mucosa must be ulcerated or inflamed and testicular pain may occur without any attack of "colic." It is upon observations of this kind that we may base the conclusion that *visceral pain expresses a perturbation of visceral function (which may or may not be due to local organic disease), while the somatic phenomena generally express a structural lesion of the wall of the viscus.*

Although his writings would lead one to suppose that he doubted the existence of true visceral pain, I am inclined to think that Sir James Mackenzie latterly accepted the sensibility to pain of the hollow organs, for in a letter which he wrote to me in 1922 he included the following sentence: "It is to answer this question that I have spent a long inquiry and have come to the conclusion that the only known stimulus that produces pain in the tissues which are supplied only by the autonomic nerves is the contraction of muscle." Perhaps we may add the suggestion that a failure to relax in the face of increased pressures produces the same effect—namely, increased tension and so pain in the muscle-fibre.

### GASTRIC PAIN.

My interest in the subject of visceral and referred pain was first stimulated by studying cases of gastric and duodenal ulcer. The pain of duodenal ulcer, usually gnawing or aching or described as a feeling of great pressure, occurs when the stomach is in the posture of approaching emptiness, but, through reflexly enhanced tonic action, its muscle becomes and remains abnormally taut. This pain is relieved when the stomach adapts its posture or relaxes to accommodate introduced food or fluid, or when the "resistance" is withdrawn and intragastric pressure reduced by complete emptying. The pain of gastric ulcer occurs when the tension in certain muscle-fibres, reflexly tautened or structurally shortened by the ulcer, is further augmented by the introduction of food. In cases of ulcer we are frequently told by the patient that these spontaneous pains are accompanied and often followed by local epigastric soreness or hyperalgesia. In a large proportion of cases we discover deep somatic tenderness. In a much smaller proportion we find superficial and deep hyperalgesia (or soreness) of the skin, together with muscular guarding of one or other rectus and exaggeration of the abdominal reflex on one side. These signs are more likely to be demonstrable if the patient has recently had an attack of pain or is in pain at the time of the examination. On the other hand, these signs may persist for days after the subsidence of all spontaneous pain as the result of appropriate treatment in bed, and they may not finally disappear for a week or fortnight. The purpose of these reflexes is surely protective, so why should they only be present when spontaneous pain is present? They disappear completely when the ulcer is healed as judged by the disappearance of occult blood from the stools, and they are not present in cases of established pyloric stenosis. They are, therefore, probably due to stimuli constantly passing from the ulcerated area to the cord, and, although they may be brought to light or reinforced by them, are not directly attributable to the painful contractions in the stomach wall which cause the visceral or deeply seated pain. These reflex signs are more constantly present with the deeper and more chronic ulcers which invade the muscular coat. Although the pain of cancer of the stomach equals or surpasses in severity the pains of gastric ulcer, it is much more rarely accompanied by somatic signs. Thus, while it is difficult to palpate deeply in many ulcer cases on account of somatic tenderness and muscular guarding, in cancer the muscles are often relaxed and the tumour can be felt without causing flinching or pain. I believe this apparent discrepancy may be related to the fact that simple ulcers erode and destroy the muscle-fibres in which the nerve-endings ramify, whereas the growth merely infiltrates between the fibres—a histological distinction which is regarded as of diagnostic import by pathologists when considering the nature of large chronic ulcers. When "guarding" is present in cancer of the stomach it is usually bilateral; in gastric ulcer it is usually left-sided, and in duodenal ulcer right-sided. Pain is referred to the back over the lower ribs, particularly in the case of posterior ulcers eroding the pancreas. Somatic signs are rarely present in simple gastritis, because the lesion is too superficial and does not involve the muscular layer. The following cases illustrate some of the points to which I have referred.

CASE 1.—J. D., male, aged about 50, was diagnosed clinically and with the aid of X rays, test-meal, and the presence of occult blood in the stools as having a duodenal ulcer. On admission to the ward he had deep cutaneous soreness, deep tenderness over the right upper rectus, and the abdominal reflex was exaggerated in the right upper quadrant. The deep soreness was very marked and at times superficial soreness was also present, the patient volunteering the statement that the weight of a book as he read in bed and even that of the bed-clothes was sometimes insupportable. The signs persisted for some time after he lost his pain, but then gradually became less and less distinct. *Deep tenderness was the last sign to disappear, and its complete disappearance coincided with the return of negative occult blood reports from the clinical laboratory.*

CASE 2.—A young man, aged 27, was diagnosed as gastric ulcer at out-patients and the X ray report confirmed, stating that there was a penetrating ulcer of the lesser curvature. On his first attendance he was free from pain and the only sign demonstrable was deep mid-line tenderness in the epigastrium. On his next visit he was actually in pain, and he showed, in addition to the mid-line tenderness, deep cutaneous soreness in the mid line, left-sided exaggeration of the abdominal reflex, and left-sided guarding.

It is very rare in my experience for superficial soreness, elicited with the head of a pin as Head [6] described, to be present in gastric disease. In distinguishing between a gastric and a duodenal ulcer the horizontal level of tenderness is less reliable than the right or left sidedness of the viscero-sensory and viscero-motor signs.

### PAIN IN GALL-BLADDER AND BILE-DUCTS.

The pain of biliary colic is referred to the gall-bladder point, corresponding with the ninth costal cartilage, or sometimes more centrally below the xiphisternum. It is almost invariably a crescendo pain. It is often difficult to dissociate the attendant gastric pain from the true gall-bladder pain. In association with gall-stones and chronic cholecystitis it is not uncommon to find a recurrent gastric pain, often worse at night, simulating the pain of ulcer and dependent upon similar reflex disturbances of gastric motility. The viscero-sensory accompaniments of cholecystitis—whether occurring with or without gall-stones—include superficial and deep soreness in the right upper quadrant of the abdomen, right subscapular and interscapular pains, and tenderness over the middle dorsal spines and along the course of the eleventh right rib. Muscular guarding, amounting in acute cases to actual rigidity, may also be present, and, in subacute cases, exaggeration of the abdominal reflex on the right side. "Shoulder pain," so often referred to as a *sign of* gall-stones, should be reserved for the description of pain referred along the phrenic nerve to the C.4 area in cases of inflammation involving the *under surface* of the diaphragm or in diaphragmatic pleurisy. It is best seen in liver abscess and subphrenic abscess and is sometimes an early symptom of a perforating gastric ulcer. I have never met with it in uncomplicated gall-stones or cholecystitis. I shall here give the notes of one case only, that of a medical man, who helped me with careful observations.

CASE 3.—Patient first came under observation on account of severe attacks of epigastric pain of unexplained causation. At the time of investigation he was free from all symptoms. A week spent in thorough investigation by the various modern methods failed to clear up the diagnosis. *The only positive sign was slight tenderness over the fifth and sixth dorsal spines, and the possibility of gall-stones was on this account considered.* A few weeks later I saw him in an attack with a palpable gall-bladder and, on the following day, a rigid right upper rectus and friction sounds below the rib margin. At operation a very much thickened and inflamed gall-bladder filled with stones was found. Some months after the operation he had one further attack of biliary colic, perhaps due to a stone left in the dilated duct. Later still I saw him with troublesome referred pains in the mid-dorsal region unaccompanied by abdominal colic or epigastric pain. I thought that these pains were due to persisting infection in the dilated ducts, and with hexamine the symptoms were at first relieved. Later, however, they recurred and hexamine failed to bring relief. The patient has since written to me in the following words: "One day it occurred to me that this pain was purely a dragging pain and might be due to inability of the liver to get rid of its secretions through a kinked duct. I decided to sleep on my left side. I could not do this before, but the difficulty was overcome. The effect was excellent. I never get that pain now unless I happen to turn on my right side, then it comes next day. I have tried the trick again and again and there can be no doubt of cause and effect . . . ."

It is difficult in this case to decide how far the referred phenomena should be regarded as an effect of inflammation and how far as an effect of mechanical distension of the ducts. In the first instance they were seemingly relieved, as I have seen them relieved in other cases, by treatment directed towards disinfection of the biliary tract. Latterly they were relieved by a simple expedient likely to facilitate evacuation of the duct. Perhaps it is fair to suggest that both factors played their part, just as mechanical and inflammatory factors are shown to buttress one another in promoting the somatic signs of gastric ulcer. Hilton [7] was the first to give an anatomical explanation for the frequent association of subscapular and interscapular pain with diseases of the upper alimentary tract, pointing out the connexions between the nerve-supply to the stomach, liver, duodenum, and pancreas (great splanchnic and solar plexus), and the fourth, fifth, and sixth dorsal nerves.

### APPENDICULAR PAIN.

Surgeons will agree that among the varieties of disease collected under the heading of acute appendicitis there are two broad clinical types which it is essential to distinguish. The first is the "inflammatory type" in which, following upon infection of the mucosa or submucosa, there develops general redness and inflammation of the organ with or without obvious pus formation. In this type, in addition to visceral pain, cutaneous hyperalgesia, muscular guarding or rigidity, and pyrexia are commonly present. If reflex signs are carefully sought for they may be found in some of the mildest and earliest cases in which it might otherwise be difficult to arrive at a diagnosis. The second type is the "gangrenous" appendix, which may give rise at first to exceedingly severe visceral pain, but not infrequently with a complete or almost complete absence of somatic signs and pyrexia. In the absence of these signs the diagnosis is sometimes unhappily postponed, and yet it is the type above all others in which early operation is imperative. In either type there may be a sudden disappearance of the visceral pain when the appendix ruptures—a strong point in support of the contention that visceral pain is an effect of increased tension. In the gangrenous type we have a lesion in which not only the lumen but also the circulation of the organ has become obstructed. Possibly the absence or paucity of somatic signs in these cases may be explained by the mechanical nature of the lesion in the early stages and by the ischæmia of the tissues involved in the later stages.

CASE 4.—A medical student aged 22 came to me some years ago with the following history: Three months previously he had had a sudden attack of pain in the epigastrium which later settled into the lower abdomen. He stated that there was tenderness on the right side and round the navel, that he vomited, and his temperature rose to 99·4° F. Forty-eight hours later he was quite well. He remained fit for a month and then had a similar attack in which there was pain and tenderness in the epigastrium. Ten days before he saw me he had had a third attack which started absolutely abruptly at 3 P.M., with pain in the epigastrium which doubled him up and made him feel cold. At 10 P.M. the pain departed with absolute suddenness under the following circumstances. He was on his way home to his rooms and met a registrar from the hospital who told him how ill he was looking. He said: "Yes, I have a bad stomach-ache . . . . No, I have not, it has gone." At no time had the pain been referred to the back, or groin, or testicle. Between the attacks he was perfectly fit in every way, and at the time of his visit to me he was quite free from symptoms. My physical overhaul was completely negative except for showing local deep tenderness at McBurney's point. A radiographic examination of his alimentary and urinary tracts was negative. Bastedo's test produced no localised pain. A week later all tenderness had disappeared and he felt perfectly well. I regarded the attacks as probably appendicular, and told him that at the first sign of any recurrence he was to come up to the hospital. As it happened the next attack started in the middle of the night, the pain was of great severity, and he could not attract the attention of anyone in the house. He came to see me in the morning looking pale and ill. There was no pyrexia, no cutaneous soreness, no rigidity, and only very slight tenderness in the right iliac fossa; the pulse was not accelerated, but as he lay on my couch he preferred to do so with the right knee drawn up. I had him admitted to hospital at once, and Mr. R. P. Rowlands removed a black gangrenous appendix. At its proximal end there was a small thorn impacted in the lumen of the organ. Although appendicular disease seemed more probable, the curiously abrupt onset and departure of pain in the early attacks and their epigastric reference had made me consider the alternative possibility of one of the major colics. With such a history before me now I should hardly dare to await events.

### INTESTINAL PAIN.

Intestinal pains are generally griping and rhythmically recurrent, but with partially obstructive lesions in the large bowel the pain may be more sustained. Excepting with ulcerative or inflammatory lesions it is unusual to find cutaneous soreness or muscular guarding in intestinal disease. These signs may be present with tuberculous ulceration of the ileo-cæcal region and with diverticulitis of the colon, but they are rare in mechanical obstructions and in cancer. Head[9] points out that they may be present in typhoid fever, but are absent in lead colic, yet another observation in favour of the suggestion that visceral pain is an effect of muscular tension, while for referred pain or tenderness the added effect of inflammation is necessary.

### RENAL AND URETERIC PAIN.

One of my most instructive lessons in visceral pain and referred pain was provided by a personal experience of renal colic. I must apologise for referring to this experience and should hesitate to do so did I not believe that personal records by medical men have a certain value of their own.

CASE 5.—In February, 1922, I began to have attacks of left-sided renal colic and between then and July of the same year, when I passed a small calculus, I had four or five major attacks and about a dozen minor ones. I was satisfied that both the renal pain, which was always crescendo in character, and later the ureteric pain, were deeply situated. At an intermediate stage the latter appeared to me to be just deep to the sacro-iliac joint, but shortly before the stone passed into the bladder it was felt low down in the left iliac fossa. One bad attack was relieved by morphia and atropine when morphia alone had failed. I was told by a colleague that my loin muscles after attacks of renal pain were hard on the affected side and they certainly remained tender for a day or two, after the manner of a muscle which has been over-used. Jolting or gentle thumping of the loin were painful, but deep palpation caused no discomfort. At no time did I discover any cutaneous hyperalgesia. There was frequent referred pain into the left testicle during the long period in which the stone was lodged in the lower end of the ureter, and this occurred quite independently of ureteric or renal crises. There were several bouts of hæmaturia, and red cells and latterly leucocytes were always present in the urine when examined. It seemed to me that the referred testicular pain was an effect of local ulceration of the ureter, although its intermittency suggested that ureteric peristalsis played a contributory part.

I have not encountered testicular pain in cases of renal colic due to an aberrant vessel, and I do not think it occurs in cases of stationary stone in the kidney. It is therefore to be regarded as a ureteric and not a pelvic or renal reference.

### UTERINE AND TUBAL PAIN.

The number of obstetric and gynæcological cases which comes my way is small, and I have few opportunities of studying their pains. As with dysmenorrhœa and parturition, so with organic disease of the uterus, back-ache in the sacral area is a common association. Pain down the front of the thighs to the knee, in the area supplied by the eleventh and twelfth dorsal and first three lumbar segments, is an interesting reference accompanying disease of the pelvic organs which I have encountered once or twice, and which Marcus [10] has particularly associated with disease of the tubes, citing several cases of salpingitis and ectopic gestation. Head [11] had concluded that the eleventh and twelfth dorsal and first lumbar were the segments involved in certain uterine cases. Hilton [7] long ago suggested that some of the so-called hysterical pains in the hip and knee might depend upon reference from the pelvic organs, and traced the path of the impulses via the sacral and lower lumbar ganglia to the sacral nerves and obturator.

### CARDIAC AND ARTERIAL PAIN.

When we consider the prevalence of cardiac disease it must be admitted that cardiac pain is a comparatively rare symptom. It is, perhaps, more common in functional derangements than in cases of valvular disease or obvious hypertrophy or dilatation. It is felt in the submammary zone and is sometimes accompanied by referred tenderness in the præcordial area.

It is remarkable that our knowledge of the cause of anginal pain has remained so indeterminate that observers of the eminence and experience of Clifford Allbutt and Mackenzie were in disagreement even as to the seat of its production. Clifford Allbutt,[12] Wenckebach,[13] and others have claimed an aortic origin; Mackenzie [2] (attributing it to muscular fatigue) a cardiac origin; and Danielopolu[14] a coronary origin for angina pectoris. The arguments weigh heavily in favour of an aortic or coronary, or at any rate an arterial origin, for the pain, and in support of this hypothesis we can enumerate: 1. The sternal situation of the pain—over the aorta or base of the heart and not in the præcordial area. 2. Its occurrence as an early symptom of syphilitic aortitis. 3. Its association with aortic but not with other valvular forms of disease, and its association with thoracic aneurysm. 4. Its absence in the majority of cases of myocardial disease and heart failure. 5. Its propagation by actions which cause a rise in intra-arterial pressure and its relief by vaso-dilatation. 6. Its not infrequent association with hyperpiesia before the development of cardiac failure. 7. Its spontaneous relief when the heart muscle fails so that an adequate pressure for the production of the pain can no longer be maintained. 8. Its segmental reference which, as Wenckebach[13] has argued, does not—on the basis of Head's work—correspond accurately with the segments supplying the heart. 9. Its close resemblance to other forms of arterial pain.

It seems reasonable to argue that angina pectoris is due to an increase in tension in the wall of the aorta or coronary vessels, or both, *depending not upon spasm but upon a failure to relax* in the face of the increasing pressures and demands which accompany increased cardiac work. Recent observations have shown that the *status anginosus* (or *sustained* anginal pain) is due generally—perhaps always—to thrombosis or embolism of the coronary arteries. We have, therefore, an apt analogy for popliteal embolism in the status anginosus, both being conditions in which *the pain is agonising and sustained*, in which the vessels are structurally damaged by stretching and inflammation, and the parts supplied by the affected vessel undergo ischæmic necrosis. Have we not an equally apt analogy for angina cruris* in angina pectoris, both being conditions in which the patient is "pulled up" and prevented from walking further by *a severe but passing pain from which he is free at rest*—a pain due, I believe, to a loss of resiliency and adaptability in the vessel wall, which is only disclosed when the muscle supplied by the vessel calls for an increased blood-supply? The referred pains are more intense and more persistent in status anginosus than in ordinary angina, just as they are more intense and persistent with an inflamed gall-bladder than after an attack of uncomplicated gall-stone colic. As with angina pectoris, so with angina cruris, we meet with "benign" cases in which the symptoms recur during months or years without any serious developments or in which recovery may take place. I believe that there are "functional" types of both conditions dependent on a neuro-muscular disturbance, and I have notes of cases in which tobacco or emotion seemed to be the underlying cause. When the symptoms depend on local organic disease then only do the graver complications follow. The areas to which pain may be referred in *angina pectoris* and status anginosus include the left breast, the inner side of the left arm to the elbow or wrist or even into the fingers, more rarely the right arm or both arms, the neck, and the jaw. The segments particularly involved are the last cervical and upper two or three dorsal segments.

## PRACTICAL APPLICATIONS OF THE STUDY OF PAIN.

Thus far my remarks have been chiefly concerned with an attempt to support (in the case of each viscus) the hypotheses set forth at the beginning of this lecture. Truism though it may seem, it is now time to remind ourselves that a working knowledge of the causes of symptoms is of great practical importance, perhaps of even greater importance to the physician than a knowledge of the causes of disease. Of all symptoms pain is the most important. In the earlier stages of our education a great deal of time was and still is quite properly devoted to the study of physical signs—that is to say, of the objective evidences of structural disease. But symptoms, being invisible and impalpable, are too often thought to be poor material for class demonstration. In practice we find that only a small proportion of our cases have physical signs; that the development of signs is nearly always preceded by a period of symptoms; and that again and again we have to base our findings on the anamnesis rather than on the physical examination. It thus becomes necessary for us to educate ourselves *in methods of analysing pains as accurately as possible*, in collecting information about their character, situation, and attendant phenomena, and the factors by which they are intensified or relieved. We have, no doubt, been taught that certain pains have certain degrees and qualities; that the severe crises like angina and renal colic are "agonising" and "unbearable"; that the "spasmodic" types of pain, as Heberden[14] remarked, are peculiarly liable to come on in the middle of the night or the early hours of the morning; that pain in the lateral organs does not as a rule cross the mid-line; that intestinal pains, like the normal peristaltic movements of the intestine, are rhythmical; that certain pains are constantly relieved by certain acts, such as the pain of duodenal ulcer by taking food; that cardiovascular pains accompany effort; that gastric pains are related to eating or fasting. Later we discover for ourselves that many other pains and discomforts, previously but dimly understood, may have their nature revealed by careful analysis, although the most experienced of us must again and again admit defeat. With hospital patients, and with private patients who can afford such luxuries, it is now possible to subject the more puzzling problems to fuller investigation and so to correct or modify an original clinical opinion. The possession of these new facilities should never, however, excuse us from careful clinical inquiry. The "pathology of the living" studied on the operation table is also a valuable corrective, but operation should rarely be resorted to for purposes of diagnosis, and the too frequent employment of the exploratory laparotomy cannot be too vigorously condemned. One of the most important things in studying pain is to endeavour to see the patient when the pain is actually present; in certain circumstances in order to assist diagnosis, it may even be justifiable to take steps to reproduce the pain. It is remarkable how rare are the opportunities in the medical wards of a hospital and in consulting practice for seeing the patient during a bout of pain. Even in general practice the patient often prefers, or is compelled, to seek advice between attacks unless he be very gravely smitten. The more observations we are able to make about a pain the more likely are we to arrive at a correct solution.

There are at least eight reasonable questions which may be put in regard to a visceral pain. These have reference to: (1) situation, (2) extent of diffusion, (3) character, (4) severity, (5) duration, (6) frequency, (7) aggravating factors, (8) relieving factors. We must also inquire about associated pains (deep and superficial) and other associated symptoms. In addition to the usual routine overhaul an examination for the presence or absence of referred signs should always be made in doubtful cases, and this is particularly important in dealing with acute or chronic abdominal disorders. The difficulties with which we have to contend are manifold. They include the limited powers of observation and description possessed by many patients; the "spreading" or exaggeration of certain pains in nervous or debilitated subjects; the minimisation of pain by others; and last, but by no means least, the shortness of life in comparison with the length of our art. In general practice there are better opportunities for seeing patients repeatedly, of observing minutely variations in the behaviour of their symptoms, and of assessing individual physical and psychological reactions to these symptoms. Those of us whose work is of a consulting kind may, on the other hand, have better opportunities for special investigations, for study in the post-mortem room, and for discussion of problems with colleagues. For all of us the surgeon, the specialist, and the pathologist from time to time will furnish proofs which have long been waited for, and occasionally a patient with unusual powers of observation may greatly illuminate some particular point of doubt.

* An alternative nomenclature for the painful seizures of intermittent claudication, employed to bring the condition into line with angina pectoris and angina abdominis.

### GROUP STUDY OF PAIN.

In conclusion, I should like to put to you the suggestion that there is no study more likely to furnish interests and rewards in practice than a concerted study of visceral or other pains. Results will come very slowly, but this need not deter you. No apparatus is required, no laboratory experience is necessary, and yet a valuable piece of clinical research can be pursued if four or more men in one town will set to work to keep and pool their notes of all cases of certain types of pain. Your interest may lead you to investigate headaches or backaches in preference to stomach-aches or heart-aches; or you may elect to investigate several varieties of ache simultaneously. You may discover nothing new in the course of years, and yet you will inevitably clear your own minds on many points which were formerly obscure, and help to establish facts hitherto imperfectly established. In this ancient haunt of learning you are particularly blessed, for you have so many eminent physiologists, pathologists, and anatomists with whom to discuss your difficulties. And finally, even though time or inclination for special inquiry be lacking, each one of us can bear in mind a saying of Hilton's which I am never tired of quoting: "Every pain has its distinct and pregnant signification, if we will but carefully search for it."

# SURGICAL TREATMENT OF CHRONIC DUODENAL AND GASTRIC ULCER:

## CHOLECYSTOGASTROSTOMY AS THE OPERATION OF CHOICE FOR INACCESSIBLE GASTRIC ULCER.*

BY L. R. BRAITHWAITE, F.R.C.S. ENG.,
SURGEON, LEEDS INFIRMARY; DIRECTOR OF SURGICAL RESEARCH, LEEDS UNIVERSITY.

### *Diagnosis.*

A DYSPEPSIA may be due to many things, but a dyspepsia which has lasted for two years and has resisted medical treatment is a serious matter. Apart from such general conditions as phthisis, it is due to organic disease in stomach or duodenum, either ulcer or malignant disease or both.

"Periodicity" is the great feature of duodenal ulcer, and to a less extent of gastric. Constancy and steady progression in intensity is the great feature of malignant disease. The onset of these latter qualities in a case which already exhibits the former indicates malignant degeneration or implantation. Gastric diseases are diseases of the prime of life, and this is especially so of duodenal ulcer. Women and men are equally effected by duodenal and by gastric ulcer. Duodenal ulcer is more than three times as common as gastric.

Malignant disease is associated with a loss of appetite amounting to a positive aversion to food. Duodenal, and to a lesser extent gastric, ulcer seems to whet the appetite; a man with a duodenal ulcer has his best time, as have most healthy people, after his biggest meal. The characteristic cachexia, the constant eructations and frequent vomiting of malignant disease are only late manifestations.

A dyspepsia due to a so-called chronic appendicitis is characterised by a mixture of the symptoms of duodenal and gastric ulcer, and is often associated with vague pain in the lower abdomen with a tenderness in the region of the appendix, where pressure may give rise to a reflex pain in the epigastrium. I do not pretend ever to diagnose appendix dyspepsia except by a process of exclusion, and that usually at a high exploration where duodenal and gastric ulcer can first be searched for.

Briefly, a duodenal ulcer pain is a "pain" before food and relieved by food, whilst a gastric ulcer pain is a "pain" after food and made worse by food. In the former case the "pain" comes on three or four hours after food; in the latter in half an hour or more. Pain which wakes a patient at 1 or 2 o'clock in the morning is a duodenal pain, and the hour at which it begins depends on the time the last meal was taken.

Symptoms of duodenal ulcer can be, and usually are, obscured by the frequent taking of food or of alkalis; and in writing a history very careful attention must be given to this point; it is never so with gastric ulcer. Possibly this fact accounts for the many cases of duodenal ulcer not recognised until perforation or hæmorrhage occurs. The patient has successfully treated his or her own symptoms.

I think there is no doubt of the seasonal variation in the pain of duodenal ulcer. Spring and autumn are the worst times of the year, but a cold east wind at any time is almost certain to precipitate an attack. Mental anxiety, indoor occupation, and lack of exercise will accentuate an attack of either duodenal or gastric ulcer. A change of climate with a holiday from work acts like a charm in a duodenal case; in few diseases is the patient more inclined to consider himself cured. Irregular meals certainly predispose to, and accentuate, duodenal ulcer, and for this reason it is seen so commonly in members of our own profession.

I have spoken of "pain," but in duodenal ulcer it is not often pain as generally understood; it is rather a vague epigastric or substernal discomfort, with a frequent desire to swallow an apparent œsophageal obstruction; this desire is satisfied by the ingestion of air, and the subsequent eructation of it affords relief. These symptoms increase in intensity as the next meal approaches, and the discomfort may localise itself over the upper part of the duodenum—that is, high up in the right half of the epigastrium—and become an actual localised pain, causing the sufferer to hold his stomach and to bend his body. With these things are associated a feeling of weariness and an irritability of temper so marked that when the patient reaches his home in the evening his one inclination is for rest, both mental and bodily. Pain running superficially along the right costal margin signifies a localised peritonitis due to inflammation, but *not* subsequent to perforation. Vomiting is rare in the uncomplicated case, but if it occurs it is vomiting of an acid fluid which scorches the throat and is swallowed again. Sometimes such a quantity of this fluid is brought up at night that it runs through the nose and soaks the pillow. Hæmorrhage which is overt is a complication. Occult blood in the stools is a sign of ulcer and should be sought for, care being taken to exclude a carnivorous dietary; it is more commonly found in duodenal than in gastric cases.

---

* Read before the York Medical Society, Jan. 16th, 1926.

The *physical signs* of duodenal ulcer, apart from pyloric obstruction and hæmatemesis which are complications, are very slight—a highly placed small stomach with a tender spot indicating the site of the ulcer

*Gastric ulcer* is a more difficult condition to diagnose; the time of onset of pain is much more indefinite, but is usually earlier after food; the "pain" is more of a real pain than that of duodenal ulcer. It is less periodic and less amenable to treatment by diet and by alkalis. The site of the pain is in the middle line or to the left and along the lesser curvature, but there is a frequent complaint of radiation to the interscapular area. Vomiting occurs more often in gastric ulcer and affords great relief Hæmatemesis is more common than in duodenal ulcer, but not so common as generally supposed In my view the "dyspeptic facies," the drawn, tired, grey face is commoner in duodenal than in gastric ulcer. In either condition the patient loses weight during an attack, and gains it in the intervals.

Mention should be made of the dyspepsia due to *gall stones* In my view it is never a painful condition except during an attack of colic. It is just a constant "flatulency" after food, with attacks of colic superimposed. In practice the story of the symptoms is sufficient, but one is never happy in suggesting operation without an X ray examination. This is a matter for X ray specialists, and I will only mention what I think are the salient points. A duodenal ulcer case should show a small, actively contracting stomach which empties rapidly; only rarely is the crater of an ulcer or a pouching of the duodenal line to be seen. Fixation of the pylorus without a crater might mean either gastric or duodenal ulcer A gastric ulcer cannot be diagnosed except by the presence of a crater or the deformity due to organic contraction; fixation of any part of the lesser curvature and accentuation of the incisura are valuable signs. A "filling defect" in the stomach is highly suggestive of malignant disease. The crater of either duodenal or gastric ulcer should be extremely sensitive to pressure It is obvious that a pyloric stenosis is a sign of mechanical obstruction and is associated with a big stomach. A pyloric spasm is difficult to recognise, but if recognised is a sign of hyperchlorhydria with or without ulcer

There are many surgeons who will not operate without a Rehfus test—i e, an estimation from hour to hour or less of the free acid in the stomach. The process of swallowing and keeping the necessary tube is much resented by most patients, and in my view, except as research on gastric secretion, is of small value.

I have thought for many years that the earlier symptoms of ulcer are due to inflammation—a congestion, a hyperacidity, and a spasm of the pylorus, with infection of, and breaking down of, Peyer's patches on both sides of the pylorus. I think the usual big gastric hæmorrhage is a weeping of blood from erosions" which are broken-down Peyer's patches. I still believe what I said in the Arris and Gale lecture in 1923—that the originating focus is in the last few inches of the small intestine, the appendix, or the cæcum, and that the spread is by lymph vessels reaching the pyloric area by aberrant channels set up by lymph blockade I think there is no doubt that this conception of the cause of ulcer very materially helps one to estimate the kind of symptoms to be expected and the kind of treatment, both medical and surgical, most likely to be of use I believe that in the absence of complications, and bearing in mind the possibility of malignant disease in case of a gastric ulcer, it is a reasonable thing to try the effect of rest, diet, and medicine for two years from the definite commencement.

It is no part of mine to speak of the details of gastro-enterostomy or gastrectomy, but rather to indicate some changes which are occurring in gastric and duodenal surgery. Before any surgical procedure is adopted it is assumed that every possible source of infection is explored and dealt with, particularly those in the mouth and nose; examination of the appendix, gall-bladder, cæcum, and the lower part of the ileum is understood to be a part of every operation.

### *Surgical Treatment of Duodenal Ulcer.*

Two chief factors enter into the question: (1) What shall be done with the ulcer? (2) Will a gastro-enterostomy or other drainage operation be necessary or advisable?

There is no doubt something should be done with the ulcer At the least it should be invaginated by sutures and covered by omental tissue, usually by uniting the gastro hepatic and the gastro-colic. Two things must be secured (*a*) the prevention of perforation; (*b*) the prevention of hæmorrhage. Suturing of the ulcer also serves to block the pylorus for a time and possibly gives rest to the ulcer, causing most of the gastric contents to pass through the anastomosis, and allowing the escape of acid juice between meals when the pylorus is closed.

The most usual method of dealing with the ulcer at Leeds is to burn out the centre completely and then suture in the ordinary way This is done to destroy the highly infective crater and also to ensure a permanent narrowing of the duodenum and therefore a partially functioning anastomosis. Other methods involve complete division of the pylorus; others ligation of the pylorus, and others (Pannett and Finsterer) complete excision of a large part of the duodenum and the pyloric end of the stomach. Finney's operation is practically a wide gastro-duodenostomy, but is described as a pyloric plastic operation.

Practically speaking, a short-circuit operation of some kind is done in every case; sometimes an ordinary gastro-enterostomy; sometimes, as strongly advocated by my colleague, Mr E. R. Flint, a gastro-duodenostomy. In my opinion a gastro-duodenostomy is to be preferred, assuming the duodenum to be sufficiently mobile or easily mobilised Gastro-enterostomy, except as a remedy for a mechanical obstruction, is becoming less popular It has many disadvantages, and its utility as a drainage operation for food in the presence of a patent pylorus is more than doubtful; in fact, the best results are those where, after a year or so, the stomach contents pass wholly, or nearly so, through the pylorus, and the new stoma does nothing except regurgitate bile, pancreatic juice, and duodenal secretion, and drains away superfluous gastric juice between meals.

One is apt to imagine the stomach as a bag hanging vertically and emptying at its lowest point. This is true of the cardia, but the contents of the mid-stomach and the pylorus are carried up along the *lesser* curvature and not at all along the *greater*, except the stomach be very full If the pylorus be open the contents will pass through it despite the new stoma. Where this movement of food fails to take place the contents may be jettisoned *at once* through the anastomosis into the small intestine, and a high intestinal intolerance with an immediate, painful, and foul diarrhœa ensues.

### *Acidity in Relation to Gastric Ulcer.*

Before considering the surgery of *gastric ulcer* it would be well to ask what is acidity?

First of all there are considerable doubts as to what constitutes *normal* acidity. Horsley[1] quotes Carlson as saying that there is to some extent a continuous secretion of gastric juice He says there is no such thing as hyperacidity, because *normal* gastric juice may contain as much as 0·5 per cent of hydrochloric acid, and the pathological variation is toward *hypo-acidity* According to his (Carlson's) observations, even "appetite" gastric juice is not essential to good digestion, and perfect health may be maintained with gastric juice of very low acidity On the other hand, examination of a very large number of cases, probably over 1000, at the Leeds Infirmary and elsewhere in Leeds, shows according to our biochemists that there is a definite and distinctive rise in the amount of free

HCl some two to three hours after food in 80 per cent. of cases found to have duodenal ulcer, though in gastric ulcer there is no characteristic wave at all.

Moynihan, at the Hunterian Society of London in January, 1923, said: "Only 20 per cent. of cases of gastric ulcer show a high normal curve of hyperchlorhydria, but 72·7 per cent. of duodenal ulcers show it." In many cases there is an apparent hypoacidity, and this when well-marked ulceration is found. It would appear, therefore, that hyperacidity, as we are able to recognise it chemically, is by no means always present, but symptomatically there is no doubt it is a most striking feature, and the relief of symptoms of both duodenal and gastric ulcers of the ingestion of alkalis is undoubted.

Donald Balfour [2] says: "While the relation between hyperacidity and ulcer is not invariable, since well-developed ulcers may exist (with a chlorhydria), the fact remains that persistent hyperacidity is one of the most prominent features of peptic ulcer."

I should like to say a few words at this point on the effect produced on the acidity of the gastric and duodenal contents by gastro-enterostomy. There is no doubt whatever—acidity is materially reduced and probably for two reasons: (1) chiefly because bile, pancreatic juice, and duodenal secretion regurgitate through the anastomosis into the stomach; (2) because the new stoma drains away the superfluous gastric juice.

C. H. Mayo [3] says: "In the surgical treatment of ulcer we have applied a well-known principle of agriculture; an acid and continuously wet soil is 'tile-drained' and its surface limed. . . . A gastro-enterostomy overcomes the effects of pyloric spasm preventing retention of gastric secretion after food has left the stomach, and by allowing sufficient quantities of the alkaline secretion of the duodenum to pass into the stomach to lower the general acids."

There is no doubt, then, in his mind that one of the great uses of gastro-enterostomy is a lowering of gastric or duodenal acidity. If it be true that the great reason for doing a gastro-enterostomy is the reduction of acidity by regurgitation of alkaline juices through the stoma, or by the drainage of superfluous gastric juice, then a gastro-duodenostomy would be a better operation and a more physiological one.

### *Surgical Treatment of Gastric Ulcer.*

Now the surgery of *gastric ulcer* has been complicated by one great factor—the possibility of a gastric ulcer or its scar becoming malignant. I say advisedly its "scar," because I believe in the natural healing of gastric ulcer. Controversy is at present raging round this very point, and I think, as in most things in surgery, both sides have gone too far, and the truth is in the middle. I strongly feel that a gastric ulcer should be excised whenever possible, and when impossible it should be cauterised after the method of Balfour, or be dealt with by suturing, but there are many gastric ulcers which are inaccessible to any local interference whatever.

I do not believe that gastro-enterostomy alone is of any real value for a gastric ulcer except possibly when the ulcer is very close to the pylorus, and even for that the best treatment is excision by partial gastrectomy. The operation usually performed until recent years was combination of excision or destruction of the ulcer with a gastro-enterostomy. The modern operation is partial gastrectomy.

Partial gastrectomy may be as easy as gastro-enterostomy, and when easy it has no higher mortality, but taking gastrectomy *in general*, I should say the mortality approaches 8 per cent. even in cases not carcinomatous. It is always a big operation—sometimes a big "adventure"—and is well borne by the patients. The results, in those which recover, are certainly better than by any other method of treatment. It is completed by suture of the cut end of the stomach to the jejunum, the duodenal stump being closed. The value of a big gastrectomy, in addition to removal of the ulcer, is the removal of a large area of acid-secreting musoca. "Sleeve resections," as advocated by Judd and Lyons [4] and by Walton,[5] aim only at a more satisfactory local excision, but do, in fact, get rid of a big area of acid-bearing mucosa.

What is required, if it can be got, is an operation which shall give rest to the ulcer and at the same time neutralise the acidity. No one operation, apart from gastrectomy, can do both. A gastro-enterostomy can reduce acidity, but cannot give peace to the ulcer.

The method of dealing with the *inaccessible ulcer* to-day is by jejunostomy—i.e., feeding the patient entirely by the jejunum to give complete rest to the stomach. This operation is satisfactory in that it does give the patient relief, but I have not known it cure; relapse takes place as soon as the tube is removed and mouth-feeding begins. I have a patient who has had a jejunostomy done three times, each time keeping his tube for two years; he was much relieved, but relapsed as soon as mouth-feeding was commenced. Rest has been achieved, but no reduction in acidity. To most people anything in the nature of feeding through an abdominal tube is most revolting.

### *Bile in the Normal Stomach.*

For a long time I have thought gastrectomy for a simple ulcer a very great mutilation, though I have recognised its efficiency. Some years ago I began to wonder whether bile, pancreatic juice, and duodenal secretion might be a beneficent factor in stomach digestion. One recognises the presence of bile in the normal stomach during ordinary digestion, and one knows of its presence there in large quantities under certain toxic conditions which give rise to vomiting. Might it be that bile, pancreatic juice, and duodenal secretion are utilised as a "protective" fluid, which is, as occasion may require, passed backwards through the pylorus into the stomach? It is also to be remembered that ulceration (except the very rare Curling's ulcer which occurs in bad cases of burns) is not seen in the duodenum at or below the bile papilla.

Glaessner has shown that giving patients sodium cholate reduces a pre-existing hyperchlorhydria. Palfrey found the same result following the administration of salol-coated pills of ox bile. Boldyreff showed by experiment that pancreatic juice and bile regurgitate into the stomach regularly after the ingestion of much fat and in the presence of large quantities of free acid. In his opinion this backward flow of alkaline juices is an attempt to neutralise an unusual gastric acidity. On the other hand, Lonnquist, Wiedemann, Rywosch, Oddi, Dastre, and Smith found by experiment that bile exerted only a small effect, if any, on the reduction of acidity.

All observers noted than an anastomosis of the *whole* of gall-bladder to the stomach, even when the *whole* of the bile (by ligature of the common bile-duct) was caused to pass through the stomach, had no deleterious effect of any kind (Cannac, Masse, Mocquot, Kehr, Jaboulay, and others). Post-mortem examinations of the animals showed no change whatever in the gastric mucosa.

In 1914 my colleague, Mr. H. Collinson, and I published in the *Journal of Surgery* an account of three cases where the duodeno-jejunal junction was completely divided, both ends closed, and a gastro-enterostomy performed. In all three there was complete tolerance by the stomach to bile and pancreatic juice, which under these conditions must pass backwards into the stomach and out through the gastro-enterostomy opening. One knows the complete tolerance of the stomach to the presence of bile in the many cases of cholecysto-gastrostomy seen and done for obstructive jaundice.

### *The Rôle of Bile in the Treatment of Gastric Ulcer.*

Dr. W. Wayne Babcock [6] was probably the first surgeon to apply the supposed virtues of *bile* to the treatment of gastric ulcer, and to suggest its use for persistent hyperacidity and pyloric spasm. He says: "Contrary to conventional opinion, bile is a normal fluid in the stomach and plays an important but poorly recognised part in gastric digestion. Its entrance into the stomach does not produce nausea or discomfort, but is associated with the cessation of gastric digestion and the arrest of motor activity of the stomach. Thus at the completion of each period of gastric digestion the pylorus normally relaxes, bile flows into the stomach, and neutralises and permanently arrests the activity of the acid pepsin in the chyme. The antrum of the stomach which has felt the brunt of the irritation of gastric digestion is coated with a protective film of the alkaline mucilaginous fluid, and the peristaltic movements of the stomach cease. We would term bile, therefore, the normal resting medium of the stomach. Were the action of the bile other than soothing its normal presence in the stomach would not so uniformly coincide with the resting period of the organ.

"Even in gastric disturbance with nausea and vomiting the pylorus relaxes and bile pours into the stomach until the entire organ is coated and bile is ejected from the mouth. From the nauseous taste of the vomit it is a common concept that the bile has disturbed the stomach, but it is much more logical to believe that the regurgitation of bile is a protective mechanism of nature, serving to neutralise the offending gastric contents and to soothe and quiet the irritated walls of the stomach. Blue litmus paper having been dipped in bile is more slowly and less intensely acted upon by acid chyme than the uncoated paper. In the duodenum and jejunum the protective influence of the bile and pancreatic juice is shown by many observations. Ulcers of upper intestine are exceedingly rare, except in the first portion of the duodenum, where there is the least opportunity for the neutralisation of the chyme by the bile and pancreatic juice. If by operation we reduce or eliminate the protective influence of the bile and pancreatic juice against the chyme in the duodenum and jejunum, ulceration becomes common.

"Exclusive of non-absorbable suture sinuses, gastrojejunostomy is followed by ulcer of the jejunum in about 2 per cent. of the cases. When the bile and pancreatic juice are diverted from a segment of the jejunum, as by the Roux gastro-enterostomy, the percentage of secondary ulcers greatly increases. In six out of seven dogs in which Exalto anastomosed the jejunum with the stomach after diverting the duodenal fluids in the colon, jejunal ulcers occurred. It is said that, unlike gastro-jejunostomy, gastroduodenostomy is not followed by jejunal ulcer. If the bile and pancreatic ducts are transplanted from the duodenum to the upper jejunum by operation, ulcers of the duodenum frequently follow. Therefore, whenever chyme from the stomach enters the upper intestinal tract without sufficient admixture with the bile and pancreatic juices, ulcers are prone to develop, and there can be little question that the latter fluids normally protect the duodenum and jejunum from ulceration. As to the exact elements that cause the ulceration, free hydrochloric acid, acid pepsin, toxins in solution, bacteria or other agents; and the precise protective elements in the duodenal fluids, alkalis, mucus, nucleo-albumin, or other substance, we will not brook unproductive dispute by attempting to name. As surgeons we think it unnecessary to enter the controversy as to whether or not peptic ulcers depend chiefly upon the hydrochloric acid content of the gastric juice."

With such complex fluids it is unnecessary to assume that a single element is entirely responsible for any particular activity. Bread is equally nourishing to the man who does not fully understand its composition, and bile may serve the surgeon not versed in its chemistry. It is important to know, however, that the so-called "peptic ulcers" have a geographical incidence corresponding to areas where the most active chyme has had the least admixture with the duodenal juices, and furthermore, that the operations that have best stood the test of experience in relieving these ulcers (gastro-enterostomy, Finney pylorectomy) are those that best permit the access of duodenal contents to the area of ulceration. The drainage function of the new opening is often negligible. Moreover, it is a striking fact that the efficiency of gastro-enterostomy for ulcer shows a close relationship with the ease of access of the duodenal juices to the ulcerated area produced by the operation. Thus ulcers that lie out of the path of the fluids passing from the new stoma along the wall of the stomach to the duodenum, such as ulcers of the lesser curvature, in a much larger proportion of cases fail to heal after the operation than ulcers about the pylorus. If it be true that it is chiefly the protective film of bile covering the mucosa that permits the average ulcer to heal, then we would suggest that the simple anastomosis of the gall-bladder into the area of ulceration or into the area left after excision of the ulcer (cholecysto-ulcerostomy) be substituted for the more formidable and difficult gastro-enterostomy.

The advantage of such an operation lies not merely in the greater accessibility of structures to be anastomosed, but in the fact that the bile is directly delivered to the part where it is most needed, while the dangers of a secondary jejunal ulcer or the other complications of a gastro-enterostomy are avoided. The continuous entrance of the bile into the stomach does not necessarily produce symptoms. Patients who have had cholecystogastrostomy performed seem to be unconscious of the increased quantity of bile in the stomach. While the bile entering the stomach after a cholecystogastrostomy reduces the total acidity, it does not abolish gastric digestion by completely neutralising the chyme. Although acid chyme is completely neutralised in the duodenum, *Dunn's* experiments show that the entrance of all the bile and pancreatic juice into the stomach will not completely alkalinise the gastric contents. Of course, the surgeon aims to protect only the irritated areas of mucosa, not to completely alter the chemistry of gastric digestion. Fortunately the normal tendency for the gastric contents to remain in well-defined strata and for fluids entering from new openings to diffuse along mucous surfaces is of aid to the surgeon.

### *Cholecystogastrostomy.*

I knew nothing of any previous work or of any writing on the possibility of the use of bile in the treatment of gastric ulcer until some two weeks ago, when, whilst gathering material for this paper, I came across a paper by F. G. Du Bose, *of Alabama*,[7] entitled "Cholecystogastrostomy and Cholecystoduodenostomy," wherein he suggests the operation as a treatment for perforated gastric or duodenal ulcer and for persistent pylorospasm due to hyperacidity, but makes no mention of having *done it*. He says, however, "Probably experience will prove that cholecystogastrostomy is as useful in gastric ulcer as gastro-enterostomy." Following on this I discovered Babcock's still earlier work and a very illuminating paper, An Experimental Study of the Effect of Cholecystogastrostomy on Gastric Acidity, by Dr. Ernest Grey, of Boston, U.S.A. In ignorance of what had already been done and written in America, in December of 1924, whilst watching my friend, Mr. G. Gordon-Taylor, do a difficult gastrectomy at the Middlesex Hospital, I said I thought the removal of such an amount of stomach for a tiny ulcer was a great mutilation, and one must find something as good, or better, and very much easier. I said I *intended to* stitch the gall-bladder into the stomach and allow bile to flow into it, and do no more.

I have never lost sight of the fact that cholecystogastrostomy brings only bile into the stomach; it obviously does not bring in pancreatic or normal duodenal fluid, but I think the undoubted beneficent effect of bile alone is proved, and it may be more than a simple reduction in acidity; bile may have other powerful qualities in the reduction of gastric disturbances.

In March, 1925, I did my first cholecystogastrostomy for *inaccessible* gastric ulcer. As so often happens with a new idea, this case was a failure; the patient succumbed on the tenth day, but from a suppurative parotitis with thrombosis of the internal jugular vein; the site of operation was found to be quite perfect and there had been no sickness. Since this time I have done, in all, 18 cases: 16 for gastric ulcer where excision or destruction of the ulcer was impossible or would have been very dangerous, 1 for a recurrent, intractable duodenal ulcer, and 1 for a hyperchlorhydria and pyloric spasm with typical duodenal symptoms. In the two latter cases a cholecystoduodenostomy was performed just beyond the pylorus.

It will be clear that this operation attempts no more than a reduction of gastric acidity. So far as I know, something in addition (possibly a jejunostomy) may be necessary to obtain rest for the stomach, but that is a matter for future consideration.

### *Results.*

You will be interested to hear what the results have been so far: four cases are in hospital now; the others have certainly been most encouraging, though it would be ridiculous to claim anything better than the immediate results of other measures. No single case has suffered in any way from the flow of bile into the stomach. In fact, there is nothing whatever to show that anything unusual has been done.

If it is eventually proved that cholecystogastrostomy gives a better result for inaccessible gastric ulcer than gastro-enterostomy (and I am very sanguine of this); if it is as good as jejunostomy (which I think likely), then I am sure, bearing in mind the drawbacks of both these operations, it may become the operation of choice. I look forward even further, and am sufficiently convinced of the correct physiological character of the operation to hope that it may become the operation of choice for every gastric ulcer and also in the modified form of cholecystoduodenostomy for all duodenal ulcers, where there is no mechanical condition requiring a short circuit.

It would be well to add that those of us who do these things do not imagine that the mechanical processes we carry out end the treatment. We only put the patient on the road to recovery. Every patient is given a dietary, and medicinal measures, aiming at a reduction both of gastroduodenal acidity and of intestinal toxæmia, are recommended.

Something should be said of the results of operation for duodenal ulcer dealt with by treatment of the ulcer and a gastro-enterostomy. About 85 per cent. are cured—i.e., are quite free from symptoms; 10 per cent. suffer from a gastro-enterostomy and modified recurrence of symptoms, and 2–5 per cent. suffer severely from a new ulcer in the gastro-enterostomy stoma.

Gastric ulcer is not so satisfactory. Donald Balfour, writing on the results of treatment of gastric ulcer chiefly by local excision and destruction, plus a gastro-enterostomy,[8] says 826 cases were dealt with; of 85 per cent. traced, 70 per cent. have complete relief, 10 per cent. are improved, and 4 per cent. have no relief.

Since writing this paper, my attention has been drawn to the following extract from a paper read at the opening of the session of the Harveian Society on Oct. 23rd, 1919, by Sir Berkeley Moynihan[9]:—

> "There is a general agreement among those who have written upon the subject of the treatment of gastric ulcers that an important part of every method consists in counteracting the normal or the increased acidity of the gastric juice. If this effect is necessary, then the physiological effect of gastro-enterostomy must play some part in causing the good results that do certainly follow at times upon its performance. Whether the partial or complete neutralisation of the acidity is necessary to healing is, however, by no means as certain as is supposed; for in cases both of gastric and duodenal ulcer hypoacidity is sometimes found. According to Friedenwald a reduction of the acidity occurs in about one-fifth of the total number in cases of gastric ulcer, and in my experience in rather more than this proportion of cases of duodenal ulcer. I have little faith in the 'physiological' action of gastro-enterostomy. If the access of bile to the stomach with its alkalinising properties were proved to be of any value, it would surely be better to anastomose the gall-bladder to the stomach, as I have many times done in cases of carcinoma of the pancreas causing obstruction to the common duct."

# ISCHÆMIC NECROSIS OF THE HEART

## IN A PATIENT TWENTY-SEVEN YEARS OLD.

*Clinical Findings by*
ERNEST BULMER, M.D., M.R.C.P. Edin., M.R.C.P. Lond.,
ASSISTANT PHYSICIAN, GENERAL HOSPITAL, BIRMINGHAM.
*Pathological Findings by*
F. W. MASON LAMB, M.B., Ch.B. Birm.,
ASSISTANT PATHOLOGIST TO THE HOSPITAL.

The appearance of numerous papers recently by various authors, notably McNee,[1] Gibson,[2] Coombs and Hadfield,[3] has stimulated interest in the correlation of a fairly typical clinical syndrome with a definite pathological process. The following case is reported owing to the extreme rarity of an ischæmic necrosis of the heart, resulting from atheroma in a patient of 27; indeed, we have been unable to trace a similar one in the literature which deals almost monotonously with the cardiac end-results of senility.

### *Clinical Findings.*

J. B., a man aged 27, had had measles in childhood, but no other exanthem. In 1915 he joined the army and was passed for active service; he was in the East for three years—Egypt, Mesopotamia, and India—and during this period contracted sandfly fever and malaria; the malarial attacks recurred until 1923. In 1917 he contracted syphilis in Mesopotamia and was treated by intravenous injections. In 1919, during a month's leave pending discharge from the army, he first developed nephritic symptoms—headache, backache, dyspnœa, and œdema of the face and legs; he consulted a private doctor who diagnosed nephritis, and referred him to the military authorities. The diagnosis was confirmed after a period of observation in a military hospital, and he was invalided out of the army with a pension for this disability.

The exacerbations recurred, and he was treated in various hospitals: the only notes available are those taken during his detention in the General Hospital from March 20th to May 10th, 1920, and from May 21st until June 11th of the same year. He was admitted with acute headache, vomiting, and diarrhœa, generalised "renal" œdema, the urine was diminished in amount and contained blood, albumin, granular and epithelial casts, with a moderately raised blood pressure. Under the usual treatment the symptoms disappeared and the patient was discharged with only a haze of albumin. These attacks continued to recur, and about Christmas, 1924, anginal symptoms first arose—an acute pain in the præcordial region, shoulder, and down the outer side of the left upper arm, coming on after exertion; the symptoms of renal insufficiency abated somewhat. Latterly the

anginal attacks have become much more frequent, and their occurrence when climbing the stairs of tramcars during the course of his work as a tram conductor made the patient extremely apprehensive.

On July 20th, 1925, the patient felt very tired, but he went to his work at 4 P.M.; on reaching up to collect his tickets from a shelf he was seized with an agonising pain in the præcordia radiating down the outer side of the left arm. His condition was so grave that he was taken without delay to hospital.

*Condition on Admission.*—He was seen at about 5 P.M. and presented the typical picture of severe angina pectoris, no organic disease was discoverable on physical examination, and the pain was quite unrelieved by the inhalation of amyl nitrite. He was admitted to the hospital, therefore, as angina pectoris, probably due to coronary apoplexy. Soon after admission morphine, gr. ¼, was given to relieve the pain; the patient's general condition grew rapidly worse, the pain was obviously unbearably severe, and he developed the signs of severe shock and left heart failure—pallor, failing pulse (temp. 96·6° F.; pulse 92; resp. 32), and subnormal temperature. He lost consciousness and died at 9.35 P.M., about five and a half hours after the onset of symptoms.

### *Pathological Findings.*

The body was that of a well-nourished and well-developed young man. The heart weighed 400 g., and was slightly enlarged. The muscle was soft and flabby, but showed no evidence of infarction or fibrosis. The bases of the aortic valve cusps were thickened by atheromatous plaques, which projected inside the semilunar folds as glistening nodular yellow excrescences. The other valves were normal.

The first part of the aorta showed very numerous fatty streaks under the intima, which was distinctly raised over them. In the left coronary artery this change was still more evident, and at a distance of half an inch from its origin the intima covering a mass of fatty material had ruptured and produced an "atheromatous" ulcer, upon which an ante-mortem thrombus had formed and completely occluded the lumen of the vessel. Beyond this point a few atheromatous patches were present, but the finer branches of the artery remained patent. The right coronary artery was normal. In the aorta there were many atheromatous areas over which the intima showed little thickening, and there was no macroscopic evidence of calcification. The intima was slightly wrinkled longitudinally, but did not present the appearance of syphilitic disease. In both iliac arteries and in the left femoral artery there were small atheromatous ulcers covered by firm thrombi. In the arteries of the circle of Willis atheromatous changes were prominent, but not of sufficient degree to cause arterial occlusion.

The kidneys weighed 400 g. each, and were considerably enlarged; the capsules stripped easily and on the smooth surface exposed there were a number of bright yellow flecks of fat, sharply defined from their dark congested background. The glomeruli were unusually prominent. The spleen (200 g.) showed some enlargement, and the capsule showed a patchy thickening with dense and rather hyaline tissue; the Malpighian bodies were prominent, and the splenic artery and its branches showed atheroma. The brain, lungs, and liver appeared normal.

Microscopically the most striking changes were seen in the aorta, the left coronary artery, and in the kidneys. The atheromatous patches in the aorta were composed of fatty débris lying in an intima, which was definitely increased by fibrous tissue formation; the fat stained well with Sudan 3. Seen with the polarising microscope, much of the fat was doubly refractile, and cholesterin crystals were identifiable. In the left coronary artery the same changes were visible, but, in addition, some of the muscle-fibres of the media contained fat which was not of the doubly refractile type. In the kidney the epithelium of many of the convoluted tubules contained fat droplets, mostly doubly refractile, otherwise the kidney changes were those of subacute nephritis. No definite evidence of syphilitic lesions could be detected.

### *Comment.*

In the pathological findings perhaps the most striking features are: 1. The large amount of fatty material present in the subendothelial coat of the aorta and left coronary artery, with comparatively little fibrous thickening of this coat, and with almost no calcification. The absence of compensatory strengthening of the vessel must have expedited an early rupture of the intima. 2. The presence of fat in the muscular tissue of the coronary artery. 3. The doubly refractile fat present in the convoluted tubules. 4. The comparative youth of the subject of these changes.

There was thus a definite nephritis associated with a profound metabolic upset, as a result of which a very widespread deposition of cholesterin and of a special type of fat took place in certain of the larger vessels, and the question arises as to whether some grotesque exaggeration of the early stages of "arterio-sclerosis" (fibrosis of the media) has not given us, by producing premature death, an insight into the pathology of the disease in what might be called the pre-fibrotic phase. The absence of obvious infarction is explained by the short duration of the coronary thrombosis.

### *Summary.*

Death, after a typical subacute or chronic nephritis with frequent acute exacerbations, was clinically due to coronary occlusion, and was diagnosed as such. At the autopsy the picture was that of subacute nephritis with a generalised arterial degeneration of a fatty type, with a terminal thrombosis of the left coronary artery at the site of an atheromatous ulcer.

We are indebted for permission to publish this case to Dr. W. H. Wynn, in whose wards in the General Hospital the patient died.

# SOME OBSERVATIONS ON THE TREATMENT OF CHRONIC DYSENTERY.

BY R. E. DRAKE-BROOKMAN, D.S.O.,
M.D. DURH.,
D.C.M.S. (TROP. DIS.), MINISTRY OF PENSIONS.

THE cases of chronic dysentery on which the following observations were made include both bacillary and amœbic dysenteries and mucous colitis in which no pathogenic organisms were isolated, as well as those cases infested with flagellates such as *Lamblia*, *Tetramitus*, and *Trichomonas*, and the *Spirochæta eurygyrata*. The cases were all pensioners treated in the clinics and hospitals of the Ministry of Pensions and the chronicity of the dysenteries varied remarkably. Whereas many hundreds have been to all intents and purposes cured, a small percentage of cases will require periodical treatment, while there are a few cases which resist every known treatment.

For convenience the cases will be divided into three classes: (1) chronic bacillary dysentery; (2) chronic amœbic dysentery; (3) mucous colitis and infestations.

### *Chronic Bacillary Dysentery.*

The causative agent, *B. dysenteriæ* of whatever variety, has, in the large majority of these cases, long disappeared from the stools. Many hundreds of cultures made from the fresh stools in these cases have proved repeatedly negative to these bacilli. It is true that *B. flexner* has been found on one or two rare occasions, but not *B. shiga*, yet I think there is little doubt that *B. flexner* does lie up embedded in the intestinal wall in the sites of the old ulcers, and from this entrenched position continue the colitis and give rise to the repeated exacerbations of the disease. These are the cases in which the sole manifestations are alternate constipation and diarrhœa with mucus and occasionally blood. It is usually necessary in these cases to continue the treatment over many months with a carefully restricted diet, when no recurrence of the clinical symptoms will take place and a cure will eventually be obtained, but the difficulty is to get many of these patients to stick to a restricted diet for any length of time. Many drugs and combinations of drugs have been tried, among them bismuth, simarubæ et puniceæ granati decoctum, intestinal antiseptics such as salol, kerol, and dimol—all with little or no temporary benefit. For some time past I have relied on either stovarsol or the mixture of tr. ferri perchlor. ℳ xx. with liq. hydrarg. perchlor. ½ drachm in ½ oz. of water, to be further diluted when taken three times daily after meals. This, when continued for months with a restricted diet and given with a nightly dose of liquid paraffin to counteract any tendency to constipation, has proved most efficacious in my hands. In those cases where there is no constipation and the stools are invariably loose I have found stovarsol of great value. It is put up in 4 gr. tablets, and I find that it can be given to out-patients one tablet twice daily for a fortnight, followed by one tablet nightly for the following fortnight without the slightest fear of any ill-effects. Its tonic effects are of distinct value in the treatment of all forms of chronic dysentery, while in the majority of cases it lessens considerably the number of daily motions. It is essential, whatever form of treatment is being carried out, that the patient be given a supply of liquid paraffin to take in the event of a tendency to constipation arising, as is so often the case; 2 drachms to half an ounce of this is recommended to be taken daily after the last meal. I have had little or no success with parathyroid and calcium lactate in the few selected cases in which I have tried them.

### *Chronic Amœbic Dysentery.*

The first thing that strikes one in these chronic amœbic cases is the unusually healthy appearance of the majority of the afflicted. A patient may be passing stools consisting of almost pure mucus and blood and yet have an appearance of well-being. It is no uncommon occurrence for a man to say that he is feeling quite well, when his stool shows active vegetative forms with much mucus and blood. These intractable cases seldom seem to pass on to amœbic liver abscess, doubtless owing to the fact that there is always a free evacuation of the active amœbæ going on. Constipation, more or less chronic, is invariably the precursor of amœbic liver abscess.

An important point in the treatment of these chronic amœbic dysenteries is to avoid pushing the use of ipecacuanha or its derivatives to excess, so as to prevent the amœbæ becoming emetine-fast. This can be done by giving the courses of treatment, notwithstanding the presence of entamœbæ in the stools, at intervals, combined with the general treatment with tonics between the courses. It frequently happens that although the entamœbæ tend to disappear from the stools the latter remain loose and frequent. In some cases the ipecacuanha even aggravates the diarrhœa for a time. The above method of administration prevents the accumulation of the drug and any after-effects which its toxicity might give rise to. Between the courses either stovarsol, yatren, or kurchi may be given for a month, then another course of ipecacuanha if the stools contain cysts, or a month's treatment with cod-liver oil and malt if the stools are free of the cysts. Yatren should be given, three pills thrice daily, for the first fortnight, then two pills thrice daily for one week, followed by one pill thrice daily for the fourth week. It is sold in 4 gr. pills and in powder. This drug has been well reported on by, among others, Muehlens,[1] Menk,[2] Kuenen,[3] and Manson-Bahr,[4] and seems to be more particularly useful in those cases where the sigmoidoscope shows definite ulceration and changes in the rectum, when a 2–4 per cent. solution can be injected and retained in situ for several hours. Under this treatment, combined with the yatren pills per os, good results have been recorded in these particular cases, but when, however, the seat of the trouble is higher up in the *cæcum* and colon, no drug can at present replace ipecacuanha and its derivatives. Kurchi seems in some cases to be a useful adjuvant, while in others massive doses of bismuth, as recommended by James and Deeks,[5] have been found to have a decided curative effect. In all cases the diet should be kept as low as possible when drugs are given per os so that there is a better chance for them to come into contact with the amœbæ. The treatment outlined above can be carried out in out-patient clinics while the more resistant cases should all be sent to hospital, where the combined emetine and bismuth treatment can be given under supervision. For some time past I have been giving bismuth. subnitras in 30 gr. doses thrice daily combined with 10 gr. of sodæ bicarb., later doubling the bismuth and keeping the treatment on for three or four months with pulv. ipecac. radix in 10–20 gr. doses in cachet at bedtime for the first month or two only.

### *Mucous Colitis with Infestations.*

Among infestations the commonest are the flagellates *Lamblia*, *Trichomonas*, and *Tetramitus*, and *Spirochæta eurygyrata*. Of these, *Lambliæ* are most frequently seen, and various forms of treatment have been from time to time advocated for their eradication. Personally, I am inclined to think that they are of little or no consequence, as, per se, they do not cause dysentery, and but little inconvenience. When, however, they are found in combination with mucous colitis following true dysentery they are apt to aggravate the condition. It is known that numerous individuals harbour *Lamblia*, and have never had either dysentery or even severe diarrhœa. After examining many patients infested with *Lamblia*, whose stools periodically show the presence of mucus and blood, I have invariably found that they have at some period of their lives suffered from either bacillary or amœbic dysentery or both.

I could quote cases of men in whom repeated stool examinations over a period of many months or even years have been negative to *B. shiga*, *B. flexner*, and *Entamœba histolytica*, and who eventually have yielded up the elusive *E. histolytica* cysts, and one at least whose fæces gave *B. flexner* after a series of negative cultures. This has led me to try in these cases the methods I have outlined above for the treatment of both bacillary and amœbic dysenteries, and after persevering with them, although *Lamblia* cysts have persisted in the stools, the dysenteric condition has been got under control and finally all signs of clinical dysentery have disappeared. Some of the patients have had regular and formed motions now for months and years and still harbour *Lamblia*.

What I have said of *Lamblia* may be said with greater assurance of *Trichomonas*, *Tetramitus*, and *Spirochæta eurygyrata*. These infestations will gradually disappear as soon as the true cause of the dysentery has been discovered and successfully treated.

As regards the drugs more recently introduced I think that yatren promises to be a most useful adjuvant to our therapeutic armament in the treatment of amœbic dysentery, and it seems to me that it should prove of distinct value as an irrigation following appendicostomy or cæcostomy in those chronic cases unaffected by ipecacuanha and its derivatives. Emetren has been tried without success in a resistant case of chronic amœbic dysentery.

My thanks are due to the Director-General Medical Services, Ministry of Pensions, for kindly permitting the publication of these notes.

# A CASE ILLUSTRATING THE VALUE OF THE SPHYGMOMANOMETER IN CARDIAC DIAGNOSIS.

BY T. STACEY WILSON, M.D. EDIN.,
F.R.C.P. LOND.,
CONSULTING PHYSICIAN, BIRMINGHAM GENERAL HOSPITAL.

A CASE such as is here recorded shows the very important assistance in diagnosis and treatment which may be given by a careful use of the sphygmomanometer.

The patient was a woman, aged about 50, suffering from broncho-pneumonia. Her face was dusky from cyanosis, her head only slightly raised on pillows, and no true orthopnœa, and she was not extremely breathless. By means of the sphygmomanometer the following facts were ascertained: The systolic pressure as judged by the finger was 138. The range of oscillation of the brachial pulse was good; there was 8 mm. of movement of the Tycos needle at 140, 4 mm. of movement observable between the pressures of 100 and 130 mm. Hg, and at 110 there was an oscillation of 5 mm.

Had there been the myocardial failure of the left ventricle which her condition seemed to suggest, there would have been a low systolic pressure and an oscillation of 3 mm. or less. The above observation, therefore, showed that the muscular vigour of the left ventricle was good, and also that there was good tonic contraction of the peripheral vessels, in spite of the fact that clinically the patient appeared to be threatened with death from heart failure.

On using the stethoscope the following facts were elicited: The systolic sound was not lost till a pressure of 148 mm. Hg was reached—namely, 10 mm. higher than the systolic pressure as judged by the finger, and the loud sound ceased at 110. This practically coincided with the results obtained by the finger The lowest limit of audibility of the sound was very low—namely, 60 mm. Hg—and a loud sound became audible at 58. The important point about the character of the sound was that between 66 and 138 mm. Hg it was very loud and almost "rapping" or "slapping" in character, and between the pressures of 86 and 110 it was extremely loud and rapping and resembled the sound which is characteristic of Graves's disease.

This type of sound and the low diastolic pressure both suggested that the arteries were badly filled, and therefore if one could have taken a tracing of the artery between those pressures of 100 and 130 we should have found that although the range of oscillation appeared to be good the pulsation of the artery would have been a very collapsing one, resembling the aortic pulse in type.

This study of the blood pressure clearly demonstrated that we were dealing with a left ventricle of good muscular vigour which was being badly filled with blood—a condition very liable to result in fatal syncope, and whose cause must be either a muscularly weak right ventricle or interference with the passage of blood through the lungs. The venous beat in the neck could be felt to be of good strength, the sounds at the tricuspid and pulmonary areas were of good tone though not distinctly accentuated. The liver was enlarged and pulsating slightly. All these facts pointed to a right ventricle of good muscular tone and therefore the cause of the patient's danger must lie in the pulmonary circulation. A relative emptiness of the left ventricle was suggested by the extreme feebleness of its sounds (in spite of the character of the arterial pulsation), by the absence of any palpable impulse, and also the absence of any cardiac dullness except quite close to the sternum.

On inquiry as to symptoms suggestive of asthmatic attacks it was ascertained that they were present, and the general presence of wheeze as well as of moist sounds (suggestive of broncho-pneumonia) confirmed this diagnosis. The case, therefore, clearly called for treatment as a case of asthma and not for cardiac stimulation, which would in all probability only have aggravated the symptoms. Such cases, as a rule, improve rapidly by treatment with stramonium both in the form of smoke from asthma powder and by ♏ 15 or more of the tincture internally every four hours. Sometimes the improvement is quite dramatic in its suddenness.

In the case in question the condition of the lungs was due to pneumonic infiltration complicated by chronic nephritis as well as to bronchial spasm, and the effect of the treatment was therefore much less rapid and effective. Nevertheless, two days later (although the general condition of the patient was showing little if any improvement) the condition of the circulation had changed.

The range of oscillation was now about normal—namely, 2 mm. at 80 and 90 mm. Hg, and 3 at 100, 2½ at 110, and ½ at 120 The systolic pressure as measured by the finger was 120 and by auscultation 120, instead of 138 and 116 respectively two days previously. The diastolic pressure was 60, and the commencement of a loud sound 66 as against 60 and 58 previously, and the rapping sound was much less loud and only heard between the pressures of 70 and 118 mm. Hg. Whereas two days previously the audibility of this sound commenced at 66 and was continued up to 138 mm. Hg In spite of these figures, which point to weakness of the heart's action, and also in spite of a pulse smaller and weaker than two days previously, the action of the left ventricle was on this date apparently more vigorous. There was a distinct and well-defined apex pulsation about the nipple line and the cardiac sounds audible over the left ventricle were much louder and showed more tone than two days previously. The venous impulses in the neck and the sounds audible over the right ventricle were much the same.

It was, therefore, justifiable to conclude that the treatment had sufficed to lessen the interference with the pulmonary circulation and that the left ventricle was being much better filled than two days ago, but that the patient was now being threatened with death from exhaustion owing to the severity of the broncho-pneumonia, and the nephritis from which she was suffering.

# Clinical and Laboratory Notes.

## THE
## LETHAL EFFECT OF ULTRA-VIOLET LIGHT
### ON NORMAL AND MALIGNANT TISSUES GROWN IN VITRO.

BY WARNFORD MOPPETT, M.B., CH.M. SYDNEY.

*(From the Department of Experimental Pathology, Lister Institute.)*

THE experiment here described was made as the extension of an observation by Dr. T. Lumsden,[1] that, when cultivated in vitro, normal cells were more susceptible than cancerous cells to temperature, bacterial infection, radium, and ultra-violet rays. An attempt was made to investigate further the effect of ultra-violet light upon normal and upon malignant tissues.

The specimens were exposed at a distance of 30 cm. from a quartz mercury-vapour lamp through a glass cover-slip 0·125 mm. thick. A quartz cover-slip was not used because glass of this thickness transmits sufficient radiant energy of wave-length down to 2300 A.U. from a mercury lamp for this purpose. A rough estimate of penetration was made by taking photographs of the mercury arc with a quartz spectograph with and without the intervention of the cover-slip. The times of exposures producing approximately equal but small density on the plate in two regions of the spectrum, 3000 to 4000 A.U. and 2300 to 3000 A.U., were compared. A definite absorption edge was observed at about 3000 A.U. Above this value eight seconds' exposure through the cover-slip produced the same density as an unscreened photograph having two seconds' exposure. Thus about 25 per cent. of the near ultra-violet and about 8 per cent. of that region between 2300 and 3000 A.U. penetrated to the growing cells. It is possible, however, that the shorter wave-lengths played a considerable part in the effect observed, for they have been shown to be those chiefly effective in destroying bacteria and protozoa, as described by Janet Clark[2] in an article on the Physiological Action of Light. Moreover, a high proportion of these rays would be absorbed by the cells, although only about 3 per cent of the total energy reached them.

The tissues were grown in ordinary serum of correct pH value as described by Dr. Lumsden,[3] a medium which maintains growth up to a month provided it be changed every few days, ample time for completing an experiment of this nature. The malignant tissues used were the mouse cancer M. 63 of the Imperial Cancer Research Fund and the Jensen rat sarcoma, both of which grow well under the above conditions. The normal tissues consisted of the kidney, heart, and spleen taken from rats and mice a few days old. The best period for experiment is the second or third day of cultivation, as growth is then well established, the cells are young and healthy, and there is a reasonable certainty that apart from any experimental interference they would continue to grow in a normal and healthy manner for the next 24 hours. Cessation of movement and ultimate disintegration of all the cells that had grown out from the fragment and adhered to the cover-slip at the time of exposure was the criterion of a positive effect. Mitosis is unusual and irregular in appearance in malignant tissues grown by this method, so that its cessation is not a suitable standard of injury. When cells have received a lethal dose characteristic changes such as shrinkage and irregularity of outline soon become manifest; it is best, however, to record the results 24 hours after exposure since the changes produced are then fully developed.

---

[1] THE LANCET, 1925, i., 383.
[2] Physiological Review, 1922, vol. ii., p. 277.
[3] THE LANCET, 1924, ii., 65.

Two similar pieces of tissue were grown on one cover-slip, one of which was shielded with lead foil. The normal unexposed cells served as a control. After exposure the cultures were not fed till observations were completed. This does not interfere with normal growth, which will continue for several days, and the possibility of re-feeding having affected the growth is eliminated. The slides were kept cover-slip upwards after exposure, since healthy cells which have been shielded by the substance of the fragment frequently grow out among the dead cells, but in the above position of the slide such new cells tend to fall to the bottom of the drop.

Under the conditions of the experiment the carpet of epithelial cells growing from a fragment of kidney was found to be the most susceptible. An exposure of 10 seconds was always a lethal dose. Fibroblasts growing from a fragment of heart muscle required about 20 minutes and the wandering cells from spleen up to 30 minutes. In the case of the Jensen rat sarcoma at least 40 minutes' exposure was necessary to kill every cell adherent to the cover-slip, while mouse cancer was still more resistant, as it required 60 to 80 minutes' exposure to obtain a similar effect. The lethal dose for particular cells was found to be about the same in different experiments, and as an insufficient exposure caused no obvious change it was possible to confirm the observation in the following manner. Normal and malignant tissues were propagated on the same cover-slip and the exposure was graduated to kill the normal tissues present and leave the malignant tissues apparently undamaged.

### *Conclusions.*

It appears that various normal and malignant tissues have different powers of resistance; the kidney is the most sensitive, the heart next, and the spleen cells, which we may regard as comparatively undifferentiated, require a lethal dose approaching that for sarcoma. The malignant tissues, however, are definitely more resistant to ultra-violet light than normal tissues when grown in vitro in this way.

I wish to express my thanks to Prof. C. J. Martin for allowing me to work at the Lister Institute and to Dr. Lumsden, who has instructed me in his method of tissue culture.

## OSTEOMYELITIS

### OF FIFTY-SIX YEARS' DURATION.

By G. B. Woodd Walker, M.A. Camb., M.R.C.S. Eng.,

HOUSE SURGEON, ST. MARY'S HOSPITAL, LONDON.

The latency of bone infections and their tendency to light up as the result of trauma or strain is particularly well illustrated by the following case.

A. W. was admitted to St. Mary's Hospital in 1870, aged 12 years, complaining of a painful red swelling above his left knee. He had been kicked a week previously, he said, by an irate gipsy. Osteomyelitis of the femur was diagnosed and confirmed at the operation when the bone was laid open. He was discharged cured. Subsequently he became a police officer. After 20 years' service, when aged 45, he received a heavy blow on the right arm during a struggle with a drunken man. Following this he was treated for osteomyelitis of the right humerus, from which a discharging sinus remained for the rest of his life.

At the age of 68, no longer a policeman, but still in official employment, he sustained a slight accident in mounting a horse van. The same evening his left thigh became painful, red and swollen, and he felt ill. He was admitted to hospital on the following day. His evening temperature was 103° F.; he was sweating and had nocturnal delirium. A very tender, red swelling just above the left knee (the original site of injury) at the back and outer side of the thigh was evident. The amount of fluid in the knee-joint was increased. The knee-joint was aspirated and turbid fluid was withdrawn. The left femur was exposed and the medullary cavity opened. A large abscess cavity filled with pus and débris was found. The cavity extended into both condyles and for a distance of 2 inches up the shaft of the bone. Staphylococci were grown from the pus.

For a time he improved and his temperature fell to normal, but on the fifth day he died from toxæmia and heart failure. At the autopsy there was evidence of bacterial infarction in the spleen and kidneys and marked arterial degeneration.

It may either be supposed that the infection lay dormant in the left femur for 56 years or that the previously damaged tissues formed a nidus to a subsequent infection. My thanks are due to Mr. Duncan Fitzwilliams for permission to publish this case.

# Medical Societies.

## MEDICO-LEGAL SOCIETY.

At a meeting of this Society held on April 20th, Lord Justice Atkin, the President, being in the chair, a paper on some aspects of the

### *New Regulations of Preservatives*

was read by Mr. C. Ainsworth Mitchell.

In the year 1921, said Mr. Mitchell, he had called attention to some of the difficulties met with in the Food and Drugs Act, both by those who had to administer the regulations and those who had to apply them. So diverse was the practice in regard to them that whether or not a conviction was obtained seemed to be chiefly a matter of geography. Local authorities in the past set up and acted upon their own standards. The regulations which would come into force next January would remove some of the present anomalies, but would carry forward some peculiar ones of their own which were likely to cause difficulties. He regretted that the evidence taken by the second committee on the subject was not published in full, as was the case with the first committee. It was difficult to see why boron preservative was not to be allowed; it could not be shown to have been more harmful than saltpetre, which had been in use from time immemorial. As to the use of salicylic acid for beverages, the first committee was misled by a trade witness who said that no preservative was necessary, and recommended that it should not be used in quantity more than 1 gr. per pint; but that witness had been found to be using a large quantity of it in his own products—namely, seven times as much. The second committee allowed the substitution of benzoic acid to 5 gr. per pint. Various deputations waited on the Minister of Health on the subject to point out the difficulties which would be met with in applying some of the regulations, and as a result modifications were issued. These modifications permitted increased proportions of preservatives in fruit pulp, pickles, and sauces. And two preservatives could be present in the same food, provided the regulation quantities were not exceeded. The amount of sulphur dioxide allowed corresponded with the fermentability of the different products. It was allowed in jam, but for some unknown reason it was prohibited in the case of orange marmalade. The regulations did not class alcohol as a preservative, though it certainly was, hence no account of it was taken in fixing the amount of preservative allowed in wine. This matter stood in need of considerable modification. Unfermented grape-juice and non-alcoholic wine made from it were allowed to contain 17 gr. benzoic acid per pint. Lemon squash, though more fermentable than grape-juice and impossible to sterilise by heat, was not allowed to contain more than 5 gr. of preservative per pint. Regulation No. 4 he regarded as a retrograde step; it stood in need of revision. He thought a declaration should be required in all cases in which preservatives were allowed. The objection urged by manufacturers was that such declaration might prejudice the sale of their products, but this was not borne out by the experience of those manufacturers who had voluntarily adopted the practice. Mr. Mitchell did not think that the consumption of beer would be reduced because it would contain three-fifths of a grain of sulphur dioxide per pint. Sweetened mineral waters might contain as much preservative as beer, and ginger-beer more, without the necessity of a declaration. Some of the foods in Schedule 1 should be transferred to Schedule 2. He anticipated difficulties in applying the regulations in the absence of generally accepted methods of determining the amounts of preservatives. He had urged upon the Ministry some standardisation, but apparently nothing had been done in the matter.

Evidently it was thought that a Ministerial warning on these matters would suffice, but Mr. Mitchell's view was that until the regulations were given statutory force there would be uncertainty as to what was and what was not permissible. The regulations which were to come into operation in January next represented the resultant of conflicting forces, but, on the whole, they could be said to be a great advance on the subject of the due preservation of food consistent with public health.

### *Discussion.*

Mr. E. HINKS (public analyst, Surrey) agreed that the whole matter was a compromise, as it must be, between what was desirable and what was feasible. In the end it would probably prove to be a matter of trial. If these instructions should bring the butter-supply to grief, there must be new regulations, but experience in the past was that what was dreaded did not usually happen. Some articles could easily be put on the market without preservatives, and sausages formed a case in point, except where they were sold long distances from the place of production. He did not think the regulations forbade preservative in marmalade. The regulations, on the whole, were a step in the right direction.

Dr. H. E. COX (public analyst, Hampstead) said there were now on the market sweetened mineral waters containing no preservative, and he thought a result of these new regulations would be that substances would be added to such beverages, constituting a retrograde step.

Mr. F. W. BECK said that for five years he had been fighting local authorities with regard to preservatives in food. He had been opposed to the general setting up of standards for foods, because in the few cases in which that had been done it had been proved to be to the detriment of the public. The law had hitherto been so unevenly administered by local authorities that it was better to have some sort of regulation. There were some borough and county benches who always followed their medical officer in cases of this kind and convicted, whatever the evidence brought forward. He was not sure that the trade felt satisfied with these new regulations, the main reason being that those concerned had not been allowed to know what was the evidence on which they had been framed. The prohibition of boric acid as a preservative was sure to be resented, and in regard to the whole matter he thought the Ministry were embarking on a dangerous experiment. Even if experience demonstrated the need for amendment, enormous damage to industries might occur in the meantime. Cold storage, for this country, was a futile proposition, though efficient on board ship and in large stores.

Dr. M. I. FINUCANE raised the question whether, in the interests of the individual consumer, it was necessary to have any artificial preservatives at all. There seemed no necessity for a scientific society to set trade and commerce on a pedestal.

Dr. KNYVETT GORDON, speaking as a bacteriologist, said one had to choose between having preservatives and bacteria, and he personally would rather have the bacteria. It was impossible to render a meat extract sterile, and in no stage of its preparation could its temperature be raised to the boiling point without spoiling the preparation. If we did not ingest many bacteria every day we should be liable to succumb to every disease which came our way, and these bacteria constituted a more effective protection than most of the vaccines specially inoculated for a set purpose. He did not think preservatives were necessary. The small quantity of formaldehyde used which the regulations coming into force next January would prohibit he was sure had not been harmful, and from the bacteriologist's standpoint it was one of the best preservatives which could be used. He spoke of an epidemic rash he had seen in children due to drinking milk heavily preserved with boric acid.

Mr. E. R. BOLTON (President of the Society of Public Analysts) said the public now knew where it stood in regard to these matters far better than before. Though the committee sometimes skated on very thin ice they had now produced something very definite. Boric acid affected some people adversely, to others it seemed to do no harm. It would have been well if the Ministry had issued a statement as to how the preservatives were to be determined.

Mr. J. R. BLANCO WHITE spoke of the conditions in France and the United States. In the former country less preservatives seemed to be used, while in the States cold storage was almost universal in the cities. One result of these regulations in this country would be that manufacturers of the cheaper articles of food would have to take more care of their products.

Mrs. BLANCO WHITE said that in 1918–19 she was in charge of a Ministry of Labour inquiry into preserved potted meats, margarine, and confectionery. The information given to the inspectors then by manufacturers did not tally with what they more recently tendered to the committee.

### *Reply.*

Mr. MITCHELL agreed that where preservatives could be done without it was advisable to omit them. Cold storage could not suddenly be put up and down the country, and if food did not keep people must expect to pay for it. Salt was a preservative, though not admitted in the regulations to be such, and he predicted that one result of these new conditions would be that certain foods would be heavily salted.

## LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society held on April 9th Mr. A. L. WHITEHEAD, the President, took the chair, and Dr. GEORGE COOPER (Leeds) read a paper on

### *Radiotherapy.*

Discussing the various conditions that responded favourably to this form of treatment, he spoke of the striking results obtained in lupus by combined treatment by artificial sunlight and local applications of the Kromayer lamp, and claimed that lupus could now be regarded as a curable disease. Very favourable results were also obtained in the treatment of rickets and tuberculous lesions by artificial sunlight, which was also being successfully used to hasten recovery in cases of chronic infection. Considering that only hopeless and inoperable cases of cancer were sent to the radiotherapeutic department, it could be said that a very fair proportion of cases of this disease yielded favourable results. Further progress in X ray therapy would probably come by the use of some sensitising agent before, during, or after X ray treatment. Dr. Cooper showed a number of cases illustrating his paper.

Dr. H. B. SCARGILL (Leeds) exhibited a large number of radiographs and lantern slides from the radiographic department of Leeds General Infirmary, and spoke of the great expansion of radiographic work at the institution during the last seven years.

Dr. L. A. ROWDEN (Leeds) demonstrated X ray photographs of hour-glass stomach, and expressed the opinion that the condition was much less frequently met with than it was 15 years ago. In his opinion the condition was sometimes congenital. In the acquired case he had seen a completely healed ulcer, although the opinion generally held was that a complete healing was rarely, if ever, found.

Dr. J. A. THOMPSON (Harrogate) demonstrated radiograms of the hip-joint showing conditions seen in spa practice. He also exhibited a series of radiograms of a case of aerophagia in a child 8 years old who suffered from chronic intermittent abdominal distension. The photographs appeared to show that the distension was due to swallowed air which finally passed into the bowel and caused distension of the small and large intestine.

## NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

AT a meeting held in Liverpool on March 19th Mr. W. GOUGH (Leeds), the President, took the chair, and Miss RUTH NICHOLSON (Liverpool) described three cases of

### *Carcinoma of the Cervix*

in women under treatment for syphilis and gonorrhœa. These cases had occurred, she said, amongst some 1500 patients at two clinics for venereal diseases under her charge for the last seven years. Another case of the sort had been reported by Arthur Helme in 1902. Gordon Luker[1] had described a case of squamous-celled carcinoma of the cervix in a 2-para, aged 28, under treatment for gonorrhœa at the London Hospital, and had remarked that no other case of a similar nature had arisen during the seven years the clinic had been in existence, emphasising the fact that the local treatment may have acted as an irritant. Herbert Spencer,[2] in his Lettsomian lectures of 1920, had stated his opinion that the relation of syphilis, soft sores, and gonorrhœa to cancer of the cervix was close, and that he had twice seen carcinoma of the cervix develop in patients who had previously had chancre of the cervix. These were the only cases which Miss Nicholson had found recorded. Her own cases were as follows:—

1. A single woman, aged 25, known to be a prostitute; no pregnancies. First seen in 1919, when she was being treated for syphilis. She then also had chronic urethritis and endocervicitis. No gonococci were demonstrated in the discharge, but later she developed salpingitis, and they were seen in vaginal smears. The treatment for syphilis was continued, and local applications of protargol and glycerine were used for the cervix for a period of five months. In 1921 she appeared with a recurrence of vaginal discharge. There were then no signs or symptoms of carcinoma. In December, 1923, she complained of intermenstrual hæmorrhage of one year's duration and was found to be suffering from a squamous-celled carcinoma of the cervix.

2. A woman, aged 40, married for 20 years, five pregnancies, all full-time living children, last eight years ago. First seen in 1921, with well-marked signs of secondary syphilis and a doubly-positive Wassermann; no primary chancre seen. No signs of gonorrhœa at that time, and smears from the cervix and vagina negative. She had probably been infected five months previously. She was treated for syphilis, and had had a negative Wassermann and no clinical signs for two and a half years. In February, 1924, three and a half years after infection and two months after her last visit to the clinic, she returned complaining of slight frequency of micturition. Vaginal examination revealed an irregular growth of the cervix, which bled readily. Microscopical section shows a luxuriant papillomatous growth originating from the columnar epithelium, which does not invade the stroma of the cervix, and therefore might be considered benign. The cells, however, are multi-layered, actively proliferating, and irregular in shape. These facts are in favour of malignancy. The closed adherent tubes show that a gonorrhœal infection was also present, and it is interesting to note that a year afterwards, on resuming marital relations, she developed acute urethritis and vaginitis, gonococci being demonstrated in smears from both orifices. Two years after operation she remains apparently free from recurrence.

3. A woman, aged 50, married 29 years; one full-time living child 28 years ago; no further pregnancies. Sent to the venereal department in June, 1925, suffering from tertiary syphilitic ulcers of the thighs. The Wassermann reaction was doubly positive. Urethritis, vaginitis, and endocervicitis were also discovered, and gonococci were found in the urethral and cervical smears. (Subtotal hysterectomy had been performed four years previously.) This patient had intravenous injections of neokharsivan and local treatment for the gonorrhœal infection for two and a half months. She stopped attending the clinic in September of last year owing to "neuritis" and reappeared four months later, in February of this year. She had noticed no discharge or hæmorrhage. On inserting the speculum to examine the cervix a small cauliflower-like mass was felt. The microscopical section showed a squamous-celled carcinoma.

In each of these cases, said Miss Nicholson, the presence of the gonorrhœal infection with its accompanying cervical discharge might have been a predisposing factor in the production of cancer. In Cases 1 and 3 local treatment might have caused further irritation. It was, of course, possible that the primary chancre had occurred upon the cervix in these cases, as it was not seen anywhere else. The youth and nulliparity of Case 1 were unusual with carcinoma, and so made it more probable that venereal infection was a factor.

Dr. H. LEITH MURRAY (Liverpool) described a case of

### *Carcinoma of the Cervix of a Prolapsed Uterus.*

The condition, he said, appeared to be surprisingly rare, this case being only the second he had seen.

Mrs. M., aged 43, gave a history of moderate and not very troublesome prolapse for some years. She had had a family of four, the last eight years previously. She had been under treatment for pulmonary tuberculosis for two years, and was considered to be holding her own; she had not recently lost weight. Her cough, however, was troublesome, and to this was attributed an aggravation of the prolapse, which had occurred during a few weeks before she saw Dr. Murray. During those weeks there became apparent for the first time, so she stated, a protrusion at the vulva, which bled readily and almost continuously.

Examination showed the patient to be thin, but not wasted. At the vulva there was a protrusion about 2¾ inches long, of sloughing, infected, friable carcinoma. The cervix was amputated and radium treatment was given. There was no recurrence of vaginal bleeding, but she died 21 months later, apparently from the lung condition. Sections even of the deepest part of the growth showed intense infection of a very active squamous carcinoma of rather unusual type.

It was of interest, said Dr. Murray, to note that the only case of carcinoma of a prolapsed uterus recorded in the *Journal of Obstetrics and Gynæcology of the British Empire* (by Dr. Russell Andrews in 1910) gave a similarly short history of protrusion, although the length of the uterus in that case made it certain that there had been a visible prolapse for some considerable time. In the present case the cervix itself lay beyond the vulva, and the protrusion was not merely a proliferative cauliflower carcinoma.

Dr. MURRAY also reported a case of

### *Hydatid Cyst of the Cervix Uteri.*

Hydatid cysts of the internal genitalia, he said, were very rare, and some, if not most, of them were undoubtedly due to direct extension from adjacent cysts.

Mrs. S., aged 32, had spent her whole life in a village on the River Dee, and had never, even for one night, been away from home. She did not keep dogs and had no particular liking for uncooked vegetables. In January, 1914, she was admitted to the Hospital for Women, Liverpool, suffering from ascites, and she was later found to have a retro-peritoneal cyst between the right kidney and the liver. This was opened. In November, 1925, she complained of pain radiating from the left of the umbilicus across the right side to the back. This had troubled her for at least ten years, and more recently she had felt when walking that there was a "big lump" in the pelvis. Examination showed a swelling the size of a 16 weeks' pregnancy, the lower pole of which depressed the vault of the vagina. There was a doubtfully cystic area posteriorly but the main mass felt solid.

Abdominal operation was done on Nov. 11th, 1925. Kelly's method of approach, by bisection of the small uterine body lying on the top of the swelling, was adopted, and after the abdomen had been thoroughly packed, an incision into the cervix was made. A cystic swelling with a thick capsule was at once exposed and opened. It was judged to be rather larger than a full-term fœtal head. Very numerous daughter cysts, varying in size from a hen's egg downwards, escaped, and, with difficulty, the cyst wall was then shelled out from the surrounding cervix. After a troublesome dissection, mainly by finger pressure, the whole of the capsule was removed in a single piece. There was no sign of any other cyst in the pelvis, abdomen, or kidney regions. It would have been impossible to remove the remaining thin shell of cervix, and the cavity, therefore, was reduced by sutures and a subtotal hysterectomy, with removal of both appendages.

---

[1] THE LANCET, 1922, ii., 71.

[2] Ibid., 1920, i., 530.

There was no doubt that the cyst lay wholly within the substance of the cervix, for a most definite and intact capsule of cervix was visible at the end of the enucleation. Its situation appeared to be in the posterior wall, but the cervical canal was not seen. There were no peritoneal adhesions whatsoever The patient made an uninterrupted recovery When seen in March 1926 she complained of some discomfort in the pelvis, and at examination a little thickening apparently in the recto-vaginal space, was felt; this was probably inflammatory

The first genuine case of primary hydatid tumour of the uterus occurring in this country, said Dr Murray, had been recorded by Giles.[3] De Vries,[4] who reported a case in 1904, found at that time only seven genuine cases in literature. Tittell[5] recorded a uterus the size of an eight months' pregnancy with ovaries each the size of a child's head; all three organs contained an enormous quantity of cysts and booklets, without evidence of hydatid cyst elsewhere. The present case could not, of course, be compared with those just quoted, except in its suggestion of infection of the uterus through the blood stream rather than the digestive tract.

Dr **ARTHUR GEMMELL** (Liverpool) reported a case of congenital absence of the vagina associated with full development of the uterus and appendages and the presence of extra digits. The patient was 18 years of age and hæmatometra and hæmatosalpinx were present. The secondary sexual characteristics were well developed Absence of the vagina associated with hæmatometra, said Dr Gemmell, was a rare condition, and he had been able to find only 14 cases in the literature.

Dr **J E GEMMELL** (Liverpool) showed a specimen of carcinoma of the body of the uterus.—Dr **J W A. HUNTER** described a case of acute post-partum œdema of the cervix and Dr **G W THEOBALD** read a paper on the Toxæmias of Pregnancy

## MANCHESTER MEDICO-CHIRURGICAL AND OBSTETRIC SOCIETY

AT a meeting of this Society held on April 21st Mr **A. C MAGIAN**, the President, took the chair and introduced a discussion on the

### *Compulsory Notification of Cancer*

Notification, he said, would show up the enormous number of cases at present unknown to statisticians. Probably many thousands of people died annually without a record of the actual cause of death because the general practitioner was apt to gloss over the matter for the sake of the relatives' feelings. This must not be counted against him, but rather against the system Notification, however, would prevent an incorrect record of a case of cancer and would also compel early treatment Early surgical treatment still gave the most successful results. Unfortunately many patients could not get early treatment at the present time owing to overcrowding of the hospitals. Notification, by calling attention to every case, would compel an increase in hospital accommodation, just as compulsory notification of tuberculosis brought about the provision of sanatoriums and clinics for the tuberculous. No doubt it would involve the appointment of many officials and produce friction and no one would be grateful for its enforcement This, however, must not stand in the way of a measure for the public good In addition to compulsory notification, Mr Magian urged that information on uterine cancer should be posted in all public conveniences for women, and that wherever notices about venereal disease were exhibited similar notices on tubercle and cancer should appear An additional 1*d* on the rates would cover the costs of notification and of new beds and would allow patients to have almost immediate attention

Dr **C MARLEY CASS** said that compulsory notification would be very hard to enforce and might cause sufferers to conceal their complaint even longer Any scheme, however, that would really bring about better accommodation and earlier treatment ought to be supported

Dr **S W H STUART** was opposed to any scheme that would lead to an increase in the present army of officials. The work of the general practitioner was becoming a burden to him by reason of the ever-increasing number of regulations and restrictions and the filling up of forms.

Dr **JOHN HOWE** thought that compulsory notification would probably be in the best interests of the patient.

Dr **ENID STOWELL**, Dr **P T CATTO**, Dr **HELM**, Dr **J G SHANKLIN**, Dr **OLIVER**, and other speakers took part in the discussion.

The **PRESIDENT**, in his reply, said that practitioners keenly resented the delays in admission to hospital. He believed that the State ought to take over the hospitals and pay the bare costs of administration The general public should then be asked to subscribe towards the extra cost of good furniture, equipment, and small luxuries. This scheme would ensure hospital accommodation at an early date for every deserving case, and yet would not remove the praiseworthy element of voluntary effort.

## ABERDEEN MEDICO CHIRURGICAL SOCIETY

A CLINICAL meeting of this Society was held on April 1st, Dr **J CROMBIE**, the President, in the chair

Dr **A. G ANDERSON** showed two patients. The first was a girl of 12 years with amyotonia congenita. The main features of the case were the extreme flaccidity of the muscles diminished reflexes, and the possibility of placing the child in fantastic attitudes. She could sit up but was unable to raise herself into a sitting posture when lying on the back. The second was a man aged 21 suffering from pseudo-hypertrophic paralysis. The condition began between the ages of 14 and 15, which, said Dr Anderson, was rather unusual. There were eight in the family. The eldest was affected, the five next were normal, and the two youngest suffered from the disease. The patient could walk fairly well and was able to pursue his university studies.

Dr **A W HENDRY** showed a woman of 25 with well marked signs of acromegaly She was seen first about a year ago when complaining of headache and fits of an epileptiform nature. These occurred every four to seven weeks. She noted the enlargement of the jaw, hands, and feet when aged 18 No abnormality of the nervous system had been found, but an X ray showed a greatly enlarged sella turcica.

Dr **JOHN CRAIG** showed a little girl who developed whooping cough in December, 1924 There were no convulsions and no unexplained fever, but on getting up in January, 1925, she noticed a weakness of the right hand arm, and leg The case was one of undoubted infantile hemiplegia. Dr Craig mentioned that athetosis was more common in cases of infantile hemiplegia than in adults. The case was shown as illustrating a rare sequel to whooping cough

Mr **G H COLT** showed a female patient aged 20 years who had suffered from a severe non-compound fracture of the right frontal bone. The unconsciousness on admission was not profound and she had bleeding from the right ear A large trephining operation was done on the night of admission and with the exception of a slight recession of the right eye and a slight inconstant nystagmoid movement and loss of memory for names—but not for faces—she had made a very good recovery The question of compensation was discussed at length

### ARABIAN MEDICINE AND ITS INFLUENCE ON THE MIDDLE AGES.

By Dr. DONALD CAMPBELL, late Captain, Royal Army Medical Corps. London: Kegan Paul, Trench, Trübner and Co., Ltd. 1926. Vol. I., pp. 208; Vol. II., pp. 235. 21*s.*

THIS painstaking book is a desirable acquisition to the store of works on medical history in English. So far as we can recollect the only other work on this subject in our language is that by the late Prof. E. G. Browne in his FitzPatrick lectures for 1919–20, a review of which appeared in our issue of August 6th, 1921. These lectures were a brilliant sketch of a period of medical history which is full of romance; while Prof. Browne treated it mainly from the picturesque, Dr. Campbell writes from the scientific point of view. Indeed, the two books may be likened to a drawing by Turner, say, the water-colour of Rouen in the National Gallery, contrasted with a sketch of the same by some strictly accurate architectural draughtsman.

The first volume is an elaborate survey of Arabic medical writings and writers in both the Eastern and Western Caliphates, and of their influence upon European learning, while a whole chapter is devoted to the Latin translators and the College at Toledo; another chapter gives a list of Arabic medical MSS. of Greek authors extant to-day. It is curious that, in speaking of Rhazes and his Liber de variolis et morbillis, Dr. Campbell does not mention Mead's translation into English (1747), although he does refer to Greenhill's (1848). We imagine that the Latin translation, which Dr. Campbell mentions as appearing in London in the same year, was that which Mead caused to be made from the Arabic by Dr. Thomas Hunt, professor of Arabic in the University of Oxford. Dr. Campbell's second volume is, perhaps, even more valuable for purposes of reference than the first, for it is made up of a careful list of translators into Latin of Arabic medical works, and a complete reconstruction of the Galenic Library as it was known in the Middle Ages. This piece of work will be a standby for medical historians. We suggest that in a future edition Dr. Campbell should always specify where a work attributed to Galen is spurious, as, for instance, the treatise De Dinamidiis. We are glad to see that the De Ingenio Sanitatis is rightly stated to be an alternative name for the Methodus Medendi, instead of the De Sanitate Tuenda, which is often given. In Nos. 126 and 205 of the catalogue there seems to be confusion as to the treatise called De Interioribus Membris or Anatomia Interiorum and the treatise De Anatomia, of which Dr. Campbell says that Greek MSS. are known. The treatise called De Interioribus Membris was probably written in Latin in the twelfth century and is often ascribed to Ricardus Anglicus. It was fathered on Galen because the prologue begins "Galienus testatur or Galieno testante," and it was therefore catalogued under Galen in European library catalogues. The old British Museum catalogues have it so, but not the present one. The De Accidenti et Morbo (No. 204) is unknown in Greek and is probably not genuine. The late Dr. Frank Payne conjectured that it might be a compendium or abstract of several books about symptoms such as the De Morborum Causis and De Symptomatum Causis. We have noted a few misprints—e.g., Vol. I., pp. 121 and 122, Chartres is spelt Chatres. In Vol. II., p. 148, De doloris capitis should read De Dolore, and on p. 189, De voce et angelitu should surely read De . . . anhelitu.

Dr. Campbell has done a fine piece of work, and the copious bibliography testifies to his industry and thirst for research. No such work can be original. The ideal medical historian would have to be an Arabic, Syriac, Greek. and mediæval Latin scholar, and in addition an expert palæographer; the equipment is too vast and various for one author. As Dr. F. J. Payne, himself an expert, said: "The whole subject of Mediæval Medical Literature is very interesting and has never been worked out thoroughly. It could only be done by studying the MSS. and comparing the different *groups* of versions which appeared at different times, and were found collected together in the same MS. The association of these versions is by no means fortuitous; but shows what books were adopted as text-books, and hence transcribed into the compendiums which were used by students, and taken away by them from Montpellier and other schools to different parts of Europe." Dr. Campbell's book is a most valuable gathering together of present-day knowledge.

### CANCER OF THE RECTUM.

By W. ERNEST MILES, F.R.C.S., Senior Surgeon to the Cancer Hospital and Surgeon to the Gordon Hospital for Diseases of the Rectum. London: Harrison and Sons, Ltd. 1926. Pp. 72. 7*s.* 6*d.*

THE Lettsomian lectures delivered by Mr. Miles in 1923 have been reprinted from the Transactions of the Medical Society of London in book form. The first lecture deals with the pathological anatomy of cancer of the rectum and its early spread, and expounds views based upon a very large experience. The second lecture describes clinical features of the disease and the general principles of treatment, and the thesis is that any operative attack from below is doomed to failure in the light of facts brought out in the first lecture. Mr. Miles's own experience in perineal excision of the rectum has been wholly unsatisfactory. The third lecture deals with the abdomino-perineal operation of which he has long been the exponent. The mortality, it is interesting to note, has been diminished enormously of late years. The author attributes this to the employment of spinal anæsthesia. The book should be read by all surgeons who operate upon such cases.

### LIGHT AND HEALTH.

By M. LUCKIESH and A. J. PACINI. Baltimore: Williams and Wilkins Company; London: Baillière, Tindall and Cox. 1926. Pp. 302. 22*s.* 6*d.*

A BOOK on biophysics that is designed for "general readers, mothers, nurses, public health officials, and others interested in health" has several obstacles to surmount. The technicalities of language are, perhaps, the least of these. The greatest stumbling-block to an author who would popularise science consists in the fact that the general reader, untrained in scientific method, cannot by himself distinguish an attractive hypothesis from a generalisation that is well substantiated by experiment. The authors plead that "a book of this sort will have little pioneering value if the authors did not venture beyond the definitely known, for conjectures are the lines of communication between the known and the unknown." Unfortunately, the reader is not often informed in the text when these excursions along the lines of communication are in progress, and, indeed, the critical reader will be tempted to wonder whether the authors themselves are always fully aware of their own boldness. The confidence with which they assert, on evidence that might well be conclusive to the general reader but is not impressive to the immunologist, that athletes in training have a greater immunity to typhoid fever than non-athletic bookworms (p. 219) is a case in point. Their suggestion, in this case it is at least plainly a suggestion, that the increase of pneumonia and influenza in the winter months occurs because we are then more anæmic from want of sunlight shows their bias. Their faith in the New York Italians' taste which, they assert, was able to distinguish the absence of vitamins in spaghetti that had been dried indoors rather than on the fire-escape (pp. 239, 240) is typical of their enthusiastic admiration of ultra-violet light.

On the other hand, their ideas on the physics of radiant energy are stimulating, also the later chapters on the physiology of light and the practical value of various systems of lighting. Experts in these subjects will use their own knowledge and experience as a safeguard against the authors' enthusiasms, while the general reader who seeks a new and not necessarily orthodox point of view will find it here.

### THE EFFECT OF FEVER ON METABOLISM.

*Untersuchungen über den Stoffwechsel des Kindes im Fieber.* By Prof. W. BIRK (Tübingen). Berlin: S. Karger. 1926. Pp. 104. M.7.

IN this monograph the author sets out the result of research which he undertook on the effect of fever on the metabolism of protein and salts in children. Previous work on the subject is reviewed, one of the objects of the investigation being to test the validity of Naunyn's expression "toxogenous protein-destruction." An account is also given of the rôle of the autonomic system in regulation of temperature and of the metabolism of albuminoids and salts, the propinquity of the centres governing these functions being indicated. The results obtained by estimation of nitrogen and salts in the food and excreta are tabulated and their interpretation is fully discussed. Disturbance of nitrogen balance was found even in the pre-febrile stage in most cases, but it was not always a loss, nitrogen retention being by no means uncommon. Among other conclusions to which the author was led are the following: the loss of albuminoids is not a direct consequence of the pyrexia, as Naunyn supposed, but is due to a toxic disturbance of the cerebral centres regulating protein metabolism. Nitrogen loss is a constant accompaniment of the febrile stage, and is probably due to temporary undernutrition; no relation could be found between this loss and the weight curve. In the post-febrile stage a loss of nitrogen or a diminished nitrogen retention was found.

### OUTLINE OF SURGICAL NURSING.

By S. J. WOODALL, M.A., M.R.C.S., L.R.C.P., D.P.H. London: Law and Local Government Publications, Ltd. 1926. Pp. 176. 5s.

THIS outline of surgical nursing appears to be a reliable little book and will doubtless be of use to nurses. There is little to find fault with and a good deal to commend. The method recommended for administering rectal saline and the apparatus depicted we should like to see more generally used. There is no reference in the index to proctoclysis or rectal saline administration. There is a slip on page 81, where a nurse, after preparing her hands for taking part in an operation, is enjoined to cover her hair completely with a sterile cap and mask, secured by tapes at the back of the head. Few nurses are likely to do this without contaminating their hands, and it would appear to be the business of an assistant.

## JOURNALS.

JOURNAL OF PHYSIOLOGY. Vol. LXI., No. 1. 1926. London: Cambridge University Press. Pp. 150. 12s. 6d.—This journal is now edited for the Physiological Society by an editorial committee composed of E. D. Adrian, A. V. Hill, J. B. Leathes, and Sir C. S. Sherrington (chairman). The first 27 pages of this issue are devoted to an article on Prof. John Newport Langley, who for over 30 years was editor of the journal, and an account is given of his life and work and a full list of his publications—over 170 in number—on work begun in 1873 and continued without intermission until his death in November, 1925.—The Effect of Stimulation of the Vagi on the Pyloric Region of the Stomach, by E. D. McCrea and B. A. McSwiney. Dissection of the anterior vagal trunk and its hepatic branch in man, dog, and cat show that the strands given off to the pylorus contain vagus fibres. The authors found that the hepatic branch of the vagus in cats and dogs supplies and regulates the pyloric region and that the movements of the isolated pyloric region are similar to those observed in the pars pylorica of the intact stomach. The pyloric region does not exhibit the property of postural adaptation. —The Influence of Exercise on the Inorganic Phosphates of the Blood and Urine, by R. E. Havard and G. A. Reay. As it is very probable that a hexose phosphate, lactacidogen, plays an important part in muscle contraction as the precursor of lactic acid, the authors sought to determine how far the inorganic phosphate of the blood is affected by the changes taking place in muscle. It was shown that after short, vigorous, unaccustomed exercise the inorganic phosphate in the blood first rises a little above, then falls considerably below, the normal value in men. In men in athletic training and taking exercise regularly this fall below normal is much less marked. There is a sudden, fleeting, but very marked increase of inorganic phosphate excretion in the urine for about three-quarters of an hour after short, vigorous exercise, followed in some cases by suppression. There is a less constant but occasionally very marked increase of ammonia excretion. There is a very marked suppression of chloride excretion during the same period. It is thought probable that the changes observed in blood phosphate are due mainly to changes in the lactacidogen content of the muscles. The changes observed in the urine seem to be due mainly to the fleeting acidosis caused by the lactic acid formed.—The Impulses Produced by Sensory Nerve-endings, Part I., by E. D. Adrian. The author has recorded the action currents accompanying afferent impulses in the frog's sciatic nerve when the gastrocnemius is stretched by a weight, and has also obtained records from the cat's internal saphenous nerve, from the cat's and rabbit's vagus when the lungs are inflated, and from the cardiac depressor nerve of the rabbit. Probably many of the oscillations observed represent action currents in a single nerve-fibre, and these have the same general form and time relations in all the sensory nerves in which they can be isolated sufficiently for measurement. There is no evidence that an increase in the stimulus increases the size of the action currents in single fibres, but the frequency of the impulses in the nerve trunk increases and leads to interference and overlapping of impulses in different fibres. When a muscle is stretched by a weight the discharge of afferent impulses continues for as long as ten minutes, provided that the tension is maintained. Similarly the passage of the impulses up the vagus continues (for as long as 20 seconds) if the lungs are held in the expanded state. No evidence was found of any renewed discharge of impulses in the vagus on deflation of the lungs.—The Elasticity of Skeletal Muscles, by J. Lindhard and J. P. Möller. The coefficient of elasticity of the excised sartorius of the frog, when resting and excited, was determined. Excitation decreased the coefficient. The decrease took place rather suddenly, while the original resting level was regained gradually and independently of the simultaneous changes in length.—The Interpretation of the Electromyogram of Striated Muscle during Contractions set up by Central Nervous Excitation, by J. G. Dusser de Barenne and J. F. G. Brevée. In the decerebrate cat the cervical spinal cord was laid bare and by mechanical stimulation, once or twice a second, of the dorsal surface "tetanic" contractions of striped muscle—e.g., *triceps brachialis*—were elicited, accompanied by frequent and irregular action currents. The frequency of these varied in different individuals from 100–200 per second; 100 may be regarded as the average. They resembled closely the action currents led off from striped muscle under other forms of central innervation, such as voluntary contraction in man, the respiratory contractions of the diaphragm, and decerebrate rigidity. In the same individual the frequency of the action currents under central innervation is the same for different strengths of contraction. What differs is their amplitude; this is larger in vigorous contractions and smaller in weaker contractions. In nearly all the experiments no appreciable diminution of the frequency of the action currents of the contracting muscle after section of the posterior roots could be observed. By producing with novocaine a local narcosis of the sensory spinal mechanisms, and thus cutting off the centripetal impulses upon the motor neurons, the frequency of the action currents was distinctly reduced. With increasing narcosis the frequency gradually became lower until there were only 50 to 70 action currents per second. At the same time the irregularity of the normal electromyogram gradually disappeared until a very regular type of action currents, often a true sinusoidal rhythm, occurred. These slow and regular action currents represent the "proper" rhythm of the impulses of the motor neurons, free from the various centripetal impulses, which play normally upon the neurons and give rise to the irregularity seen in the normal. The electromyogram of striped muscle during contractions of central origin is a true image of the central impulses reaching the muscle from the central nervous system along the peripheral motor nerve-fibres.—On the Factors Concerned in the Production of Pulmonary Œdema, by R. K. Lambert and H. Gremels. A dog's heart-lung preparation was used, the circulating fluid being defibrinated dog's blood. Œdema supervened rapidly (½–1 hour) if defibrinated blood which had stood for 24 hours was used or if metallic poisons were introduced into circulation. Degenerative changes occurred in capillary endothelium of lungs and heart. The œdema in its initial stages was unattended by changes in resistance of blood flow through lungs. The authors suggest that toxic action of blood may be partly responsible for pulmonary or cardiac œdema observed clinically.—The In Vivo Permeability of the Red Corpuscles of the Rabbit, by J. T. Irving and H. D. Kay. An attempt has been made to determine whether the administration of insulin to the rabbit brings about permeability changes in certain of its body cells. In preliminary experiments the partition of sugar or, better, reducing substance between the corpuscles and the plasma was determined before and at intervals after the injection of insulin. The reducing substance in the corpuscles did not decrease in a manner parallel with the decrease in plasma "sugar" during the hypoglycæmic period. Can any changes in the permeability be brought about by insulin injected in vivo? It was found that in the blood of the normal rabbit only a relatively small proportion—0·02 per cent. reckoned as glucose—of the reducing substance is present in the corpuscles. Addition of anticoagulants—sodium citrate and others—to shed blood alters fundamentally the permeability of the corpuscular membrane to reducing substance. The amount of reducing substance in the rabbit's corpuscle in vivo is both relatively and absolutely increased by previous injection of insulin, of "inactivated insulin"—i.e., insulin rendered no longer capable of producing hypoglycæmia when injected into rabbits, but otherwise changed as little as possible—and of peptone solutions. It is almost certain that glucose is still present in rabbit's blood at the stage of hypoglycæmia at which convulsions occur. Until a pure substance of definite chemical composition is isolated the name "insulin" cannot be precisely used, and may cover a number of factors beside the one producing hypoglycæmia.—On the Nature and Significance of Vagus Escape, by R. J. S. McDowall. Isolated observations of other workers have suggested that vagus escape may be due to increased blood pressure in right side of heart. Experiments on anæsthetised cats showed striking rise of venous pressure on vagus stimulation; after a brief period heart was markedly accelerated. If the rise in venous pressure was prevented, vagus escape did not occur.—The Action of Adrenalin and Ergotamine on the Uterus of the Rabbit, by J. H. Gaddum. The effects of these two drugs on rabbits' uterus—pregnant and non-pregnant—were studied on parts of the organ suspended in a bath of Ringer's fluid.—The Relation of Secretin Formation to the Entrance of Acid Chyme into the Small Intestine: the Properties of Secretin, by J. Mellanby and A. St. G. Huggett. An account of this paper will be found on p. 920 of this issue of THE LANCET.

THE INDIAN JOURNAL OF MEDICAL RESEARCH for January, 1926, records an accomplished activity in the investigation of clinical, pathological, and sanitary problems in which India may well take interest and pride. Shortt, Bairand, and Craighead describe and illustrate a massive infection of the pharynx of *Phlebotomus argentipes* with *Herpetomonas donovani* eight days after feeding on a kala-azar case.—Hutchinson's well-illustrated and informative paper on photography from the microscope is timely, in view of the growing habit of microphotographic illustration, and its not infrequent failure to illustrate.—Cornwall and Beer, studying paralyses after treatment with antirabic vaccine, find that fresh normal nerve substance is toxic to both rabbits and men when injected subcutaneously; some showing paralysis after less than 20 mgm. per kilo body-weight, others tolerating easily 1 g. per kilo. Phenol renders the nerve substance slightly less toxic. It is desirable to be able to increase the dose of the antigen, and it is more practicable to neutralise the toxicity of the vehicle than to separate the antigen from it.—Greval and Row give a careful account of the first case of undulant fever diagnosed and treated in Aden.—Mundaliar, Raman, and Menon describe a case of kala-azar in whom the infection must have been acquired on the *west coast* of India. They suggest that the geographical distribution of kala-azar in India requires revision.—Covell, using the Clayton Lane technique in a hookworm survey of the troops in Dehra Dun, finds the Gurkhas' infection twice as high as that of the gunners and drivers recruited in the Punjab. It is suggested that a hookworm survey of all Indian troops be carried out, using, for diagnosis, Clayton Lane's method of direct centrifugal floatation; it is easy, rapid, and accurate; and for mass treatment beta-naphthol.—Sinton, from his studies in malaria, with special reference to treatment, concludes that, in the malignant tertian malaria of Northern India, 30 gr. quinine daily for one week, combined with alkaline treatment (mist. sodii bicarb. gr. 60, sod. cit. gr. 40, calc. carb. gr. 2½, aq. ad. 1 oz.) cures at least 80 per cent. of cases, and that patients infected with *P. falciparum* are much more easily cured by the same doses of quinine than are those infected with *P. vivax*. He found little or no advantage was gained in the diagnosis of uncured malarial infections by provocative infections of adrenalin or strychnine.—Arland describes the remarkable rejuvenescence of body and mind, and the sexual recovery, observed in two aged, decrepit, tremulous, and sexually unresponsive Busrah "country" dogs, after vaso-ligation.—Brahmachari records a case of hæmoglobinuria in a boy, aged 14 years, whose peripheral blood and liver puncture smears revealed L.D. bodies and no malarial parasites. Hæmoglobinuria began six hours after oral administration of 8 gr. quinine, and increased and diminished concurrently with the fever paroxysms. There was a large hard spleen, and fever intermittent with double rises every 24 hours. When the hæmoglobinuria was passing off, the blood from liver showed distinct hæmolysis; at the same time the peripheral blood showed very faint hæmolysis, and the urine very slight hæmoglobinuria. In the liver, therefore, there was active hæmolysis, as in the case of quinine hæmoglobinuria previously recorded by him and Sen. This is the second case in which he had found hæmoglobinuria in kala-azar. The whole volume of 26 papers, all of high standard and interest, by various authors, some only of whom have been mentioned above, may confidently be recommended, especially to all engaged in tropical medicine.

THE LANCET.

LONDON: SATURDAY, MAY 1, 1926.

## ECONOMY BILL: SOME MEDICAL ASPECTS.

THE Budget figures put forward with great clearness by the Chancellor of the Exchequer show the difficulty of securing a credit balance in national finances—and that without taking the coal menace into consideration. Thus those who demur at any processes of economy should show grounds for a belief that the particular measures for saving will result either in waste of previous efforts on which money has been spent, or in an increase of expenditure in the near future. On both these grounds many of the medical profession view with apprehension certain sections of the Economy (Miscellaneous Provisions) Bill. Various amendments brought forward when the Bill was in committee, pleading for the omission of clauses which might be worked in a manner prejudicial to health, were rejected by large majorities, voting being practically on party lines. The medical profession recognise as good citizens that money must be found with which to carry on, and it is to be hoped that some of the forebodings expressed in the amendments will not prove true, and that valuable activities in behalf of public health, of the health of children especially, will not have to be curtailed until their utility is gone. Anything like a supervision of local education which allows, for example, the spread of ringworm through relaxation of the methods for its control will be deplorable, even though it can be supported by some calculation of averages extending over and applied to various areas.

In one of the debates Sir JOHN SIMON told a story of a treatise by a learned continental physician. In the body of the treatise it was said that on an average a certain rare disease attacked the human race at about 45 years of age, and in an appendix a record of the cases was given; they amounted to two—in one the disease removed an infant of six months, and in the other it terminated the career of a nonagenarian. The value of averages, wrongly used, is well illustrated by this joke, and Mr. STANLEY MORRISON pointed out that a significant meaning lay beneath it. There are 526 special schools in England and Wales providing education for the blind, the deaf, and the physically and mentally defective, of which London maintains 174. Mr. MORRISON urged that this splendid system of special schools, which ought to serve as a standard to which other centres should average up, might—the watchword being rigid economy—lose its efficiency by the average being taken downwards. In similar vein Dr. HADEN GUEST, speaking as a past medical inspector for the London County Council, indicated the impossibility of arriving at comparisons as between one area and another in respect of school population, a population which, he said, must be regarded medically from the point of view that the children are human beings and not from the point of view of the money expended. Dr. DRUMMOND SHIELS supported an amendment which by limiting the proposed measures of economy to new educational expenditure would leave unhampered existing progressive measures, and found an apt illustration in the practice of dentistry. He pointed out that dental trouble was being reduced to a very large extent owing to the activities of the dental centres, and that a wide movement, successfully inaugurated in London, was fast taking root in the provinces, a position which, he urged, ought not to be altered for the worse, even if it could not be promoted by larger support. The practical outcome of these and similar representations was nil as far as any alteration in the measure, but good must have been done by the warnings. Ill-health, and especially ill-health in the young, is a costly and wasteful affair to the community, and under the wide discretions which the Economy Bill will allow, it must be hoped that this will always be remembered by the authorities. It is far easier to closure health activities than it is to set them going—levelling-down is simple and levelling-up is hard.

◆

## CEREBRAL TUMOURS.

THE second scientific sitting of the International Congress of Surgery, held a few days ago at Rome, was given up to the consideration of cerebral tumours, and was remarkable for the great variety of opinions expressed as to the best methods of treatment and the results which might be expected. The wide differences in technique of the different surgeons who shared in the discussion showed what an immense amount of attention has in recent years been paid to this difficult branch of surgery, and it suggested that, in spite of all the advances which have been made, the perfect technique for opening the skull has yet to be discovered. On certain points there was universal agreement such as:—the importance of early diagnosis and of operation before the symptoms of general pressure have appeared; the necessity for perfect hæmostasis in the early stages of each operation, and for conserving the patient's resources to meet the formidable demands made upon him when pressure is released; and close collaboration between the surgeon and the neurologist at every stage both of diagnosis and of treatment.

In opening the discussion Mr. HANS BRUN (Lucerne) described in great detail his technique for craniotomy, founding his observations on his own series of 458 cases. Operating entirely with local anæsthesia he takes the most extreme precautions to prevent the slightest loss of blood, making his incision in very short sections and ligaturing every artery as it appears. After drilling a preliminary hole with a burr, he divides the bone exclusively with Krause forceps, packing each section of the groove with gauze impregnated with a solution of gelatin. Where he operates in two stages he does not raise the osseous flap at the first stage, but contents himself with a mere division of the bone around the free margin of his flap. On raising the flap at the second operation he thus has the advantage of exposing a dura mater which has not been disturbed. Dr. DE MARTEL (Paris) adopts an entirely different technique (in his absence his paper was circulated at the Congress), although he also operates under local anæsthesia. After incising the scalp with every precaution to avoid loss of blood he divides the bone by mechanical means, using a powerful engine of his own device, fitted either with a special burr or with a circular saw. By these means the dura mater is reached with rapidity and apparently without discomfort to the patient. He lays stress on opening the dura only after reducing cerebral tension by ventricular puncture, hypotonic intravenous injections, or rectal injection of magnesium sulphate. Mr. PERCY SARGENT (London) (also unable to be at the Congress) presented a paper of great interest founded upon his own series of 336 operations for cerebral tumour. He laid great stress upon a knowledge of the exact situation of a tumour, its pathological nature, and the degree of intracranial pressure to which it had already given rise. He pointed out how mistaken was the idea that the trinity of headache, vomiting, and optic neuritis was the true index of cerebral tumour, regarding these rather as indications of impending death, and he urged the importance of learning to appreciate early symptoms, and especially the first signs of papillœdema. It was possible, he thought, to diagnose the situation of a tumour correctly in 90 per cent. of cases by clinical means alone, and he deprecated the necessity for such methods as ventriculography. A consideration of the history of the case and of the ascertained situation of the tumour often made it possible to form a shrewd idea of its histological nature. Thus cerebello-pontine tumours are mostly neuro-fibromata, pituitary tumours are adenomata, and cerebellar tumours are gliomata. Tumours of the cerebrum are almost invariably gliomata or endotheliomata, and even in the frontal and post-central regions where endotheliomata are most common, the gliomata out-number them by two to one. Mr. SARGENT'S statistics repay study. In summing up his experience of cerebral glioma, he stated that about 25 per cent. of the patients die shortly after operation, about 50 per cent. within eight months, leaving 25 per cent. to make a good recovery, many of them being able for several years to live useful lives and earn their own living. The outlook is more favourable than this with cerebellar glioma, for symptoms tend to arise at an earlier stage, the tumours show a remarkable tendency to cystic degeneration, and lost cerebellar function is readily compensated. As compared with glioma of the cerebrum the operative mortality is less than half, the proportion of good recovery is higher, and the average survival nearly twice as long. Oddly enough the operative mortality of endothelioma exceeds that of glioma, presumably owing to the radical nature of the procedure, but Mr. SARGENT can point to 46 per cent. of good recoveries after removal.

Later in the sitting Prof. ARCHIBALD YOUNG (Glasgow) contributed some interesting statistics and described a novel procedure for supporting the bulging brain after extensive trephining for decompression. Prof. ADSON, of the Mayo Clinic, gave a fine cinematograph demonstration of trigeminal neuralgia and its treatment. The discussion concluded with a debate on different methods of opening the skull. Mr. A. R. JENTZER (Geneva) showed an ingenious trephine by means of which a disc of bone, two and a half inches in diameter, can be rapidly removed without the slightest risk of injury to the dura; and Mr. H. S. SOUTTAR (London) showed a new form of craniotome in which a cutter, fitted to a powerful lever, turns round an axis which has first been fixed to the skull itself, so that large osteoplastic flaps can be fashioned with ease and rapidity. The sitting suffered, as all such international occasions must suffer, from the volume of material presented and the limited opportunity available for discussion. All who are interested in cerebral surgery should read the papers as they appear at length in the printed proceedings of the Congress.

# THE TECHNIQUE OF PERORAL ENDOSCOPY.

DIRECT visual examination of the bronchi and œsophagus has its home in Jefferson College, Philadelphia, where the genius of a CHEVALIER JACKSON has brought its technique to a high level of exactitude. In his Lumleian lectures, delivered before the Royal College of Physicians of London two years ago, one of Prof. JACKSON'S colleagues, Prof. THOMAS MCCRAE, told the story of the bronchoscopic clinic associated with the University Hospital in Philadelphia as seen by the physician attached to it. In a series of 1300 cases of foreign body in the bronchus JACKSON, we learn, did not fail once to remove the body by means of the bronchoscope, usually within a few seconds. This exploit was brought home graphically to the medical profession in this country by Prof. MCCRAE'S illustrations of the varied foreign bodies removed in this way. These pictures, which were reproduced in our columns [1] at the time, showed dental plates and instruments of various kinds found impacted in the air-tubes, numberless safety-pins removed from trachea and bronchi, tacks and staples retrieved from all parts of the bronchial tree, a variety of toys, of which the larger sorts had lodged in the œsophagus, and a wonderful collection of seeds and shells which had found a nidus in some part of the respiratory tract. The inhaled objects of vegetable origin had a certain local colour, for in 100 consecutive cases a pea-nut or a portion of one was found in 45, a grain of maize in 17, and a water-melon seed in 15. Prof. MCCRAE'S lectures dealt in detail with the signs and symptoms produced by foreign bodies so introduced, with the diagnosis which was often only made after radiological examination, and quite briefly with the treatment. We are now able to publish a description from Prof. JACKSON'S pen (see p. 924) of the technique used at the bronchoscopic clinic.

One of the outstanding features of this clinic is the team of perfectly trained assistants of which, as Prof. JACKSON says, "every member is drilled for months in the steps" of the routine of endoscopic procedure; as a result, in easy and in difficult cases alike, the necessary manipulations are performed as though by clockwork. Doubtless the number of cases dealt with at the clinic, and the consequent opportunities for practice, are far greater than fall to the lot of any institution in this country. This is partly due to geographical conditions, partly to the pea-nut habit—and it may be noted in this connexion that the majority of foreign-body cases occur in babies—but largely, no doubt, to the reputation which Prof. JACKSON and his clinic have acquired. Where the opportunities are less, such a high degree of perfection is unattainable; and it is difficult to see how an approach to this perfection can be made in a London hospital, with its frequent changes of house surgeons and clinical assistants. Nevertheless, a careful study of Prof. JACKSON'S methods must be of great value to any endoscopist, particularly in the matter of the "Boyce position" for the patient, and of the duties and attitude of the first assistant. A further point of great interest is the question of anæsthesia; at the Philadelphia clinic general anæsthesia is not used for any endoscopic procedure, the chief reason being that "it is dangerous in certain cases and needless in any case." Cocaine is used in adults for direct laryngoscopy and for bronchoscopy, but not for œsophagoscopy, and not at all in children; morphia is usually given before a first bronchoscopy, and is sometimes combined with atropine or hyoscine. It is well known that the œsophagus is almost insensitive; the bronchial tree is now shown to be less sensitive than has been supposed. and doubtless the endoscopist might dispense with anæsthesia more often in this country. But the temperament of patients is a very variable factor; in nervous cases, with throats rendered irritable by tobacco and alcohol, it is sometimes difficult to make an adequate examination even of the tonsils We all know the spoilt, undisciplined, frightened child of 7 or 8 years old, in whom the simplest examination is very troublesome, and it is hard to understand how such a child is persuaded to submit quietly to bronchoscopy without the use of any form of anæsthesia. The highly perfected team-work of the Philadelphia clinic doubtless makes for great dexterity, but the American, as a race, is not more phlegmatic than the Briton, and it is probable that the occasional bronchoscopist will still have to resort to general anæsthesia, at any rate, for his more nervous and irritable subjects.

## THE ARCH OF THE FOOT.

ALTHOUGH the various forms of pes cavus and claw-foot are common enough in England and are in general adequately treated, not much has been written about them in this country. In some of the largest and best known works on orthopædic surgery in our language the subject is dismissed without much consideration of details, as though its importance were small or its cure easy by obvious methods Yet this deformity often gives rise to grave disability and pain, and shows itself most obstinately defiant of many attempts at cure. In considering pes cavus, as to a lesser degree in considering flat-foot, we are met at the outset with the difficulty of defining the normal arch of the foot. At the two ends of the scale of severity it is easy enough to distinguish flat-foot and pes cavus respectively, but the further we go from the extremes the more difficult does definition become. Races of men and individuals differ very widely in the shape of their foot-soles; the aristocratic foot "under which a mouse could run" on the one hand, and the foot with an almost non-existent arch on the other, may both be perfectly good feet from a functional point of view, and give no trouble to their owners Some years ago an attempt was made at a large New England hospital to forecast the future of the feet of some hundreds of nursing probationers The result was disappointing, for the observers failed to find any constant relation between defects detected on entry and subsequent breakdowns in training in the wards of the hospital. In severe and advanced cases, where radical operations on the bones are justifiable, treatment may no doubt be simple if severe But in the vast majority of cases in which such mutilating procedures cannot be justified, the cure is often uncertain and the treatment is nearly always tedious. Dr. Hackenbroch[1] describes and discusses the pathological anatomy of the different grades of deformity and their operative treatment, ranging from fasciotomy to tarsectomy, not omitting the various tendon-transfer operations which have found favour with some surgeons. In something like 30,000 words and with the help of 40 illustrations he has given us a very full account of the subject, and one which should be of practical use to all surgeons who may be in doubt as to the best means of treating this deformity, for in this monograph they may find recorded most, if not all, of the procedures that have been devised for its relief.

"Ne quid nimis."

## THE MAUDSLEY HOSPITAL.

PSYCHIATRY, which among primitive peoples is the earliest and most important branch of medicine, is, in civilised countries, only just coming into its own. In the middle of the last century many great physicians recognised that the mind had its diseases, and gave themselves to its study; then came a sudden expansion of interest in pathology and a dark period during which men declined to believe in the reality of diseases for which they could find no physical cause. From this attack of "parallelism" the science of mental disease is just rallying. Although it has not yet reached the position it deserves, it has attracted some of the greatest minds in medicine, and is subduing the forces of pathology to its own ends. It was only to be expected that the swing of the pendulum would bring uppermost the opposite view, that all disease, physical and mental, is the result of mental disturbance; the schools of psychology have increased and multiplied, and signs are not wanting of a tendency to neglect the demonstrable facts of biology and to introduce into the study of mental disease an element of ingenious psychological speculation that, while affording great satisfaction to its exponents, is not likely to contribute much help to the clinician, who is, after all, the person who matters most. Against this danger the Maudsley Hospital is a valuable defence. Those who direct its policy are not only psychiatrists of experience and skill, but they have a deep respect for hard work and patient research in pathology, biology, and chemistry. The essence of their attitude is that mind and body are one, that one cannot become disordered without the other, and that the only way to a full understanding of the secrets of mental disease is the proof, step by step, of the accompanying physical changes. Everyone knows in what a chaos the science of psychiatry is to-day; each author has his own classification and his own explanation of its problems, and nearly everything is empirical. But clinical certainty can only be built on a basis of pathological proof, and the workers in the well-equipped modern laboratories of the Maudsley Hospital have every chance of building the foundations of a scientific psychiatry. Their work on metabolism, vaso-motor reactions, hydrogen-ion concentration, and many other subjects is well known, and they are fortunate also in being connected with a hospital where the nurses are enthusiastic enough to give up their time and comfort to act as controls, and where the medical officers add to their heavy routine work by collaborating in or initiating research work.

It is regrettable that the issue of the report of the Maudsley Hospital, in common with many other official publications, is so tardy. The booklet just published only takes the history of the institution up to Jan. 31st, 1925, and the work reported is already out of date It serves to remind us, however, that this important experiment of the London County Council is fulfilling the hopes of those who conceived it and achieving its objects of facilitating research and teaching in psychological medicine and providing treatment for voluntary patients suffering from mental disorders of all degrees of severity. During its second year 1304 patients were treated, an increase of 300 over the number in 1923. The preponderance of female applicants for admission was so unexpectedly large that the accommodation had to be rearranged, until finally 96 out of the 144 beds were allotted to women. The hospital's policy of admitting mild, severe, and psychophysical cases together has met with a good deal of criticism, but the results have justified the innovation. The Maudsley has ample facilities for treating cases of slight mental disturbance accompanying such physical conditions as exophthalmic goitre and chorea, for it has the advantage of the coöperation of the consulting staff of King's

College Hospital. Moreover, in the present empirical state of psychiatric science, it is of the first importance to study those mental conditions that have a well-defined pathological basis, if the pathology of those which are as yet little understood is ever to be made clear. To make the Maudsley a clinic for mild cases only would defeat its end of furthering the study of mental disease as a whole, and would deprive it of a unique and valuable characteristic. The work of the out-patient department has increased considerably since the beginning of 1924, and the now insufficient accommodation is to be extended. The medical superintendent feels that the future success of the department will depend on an adequate supply of experienced clinical assistants, who will see most of the cases and leave the senior medical officers free to see new patients and those whose disposal is still uncertain. For chronic cases out-patient treatment can be only palliative, but it is none the less valuable in enabling many to "carry on" who would collapse without the periodic encouragement of "therapeutic conversation" and a little bromide, and it is actually preferable for watching and stimulating neurotics, who might drift into an asylum to shirk their difficulties. The arrangements for treating in-patients are exemplary. It is possible to keep three-fifths of the acute cases in bed in the open air in all weather, and when two bridges are covered in this accommodation will be increased. Massage, remedial exercises, and electrotherapy are extensively used. A special "occupations officer" attends three afternoons a week to instruct patients in a large number of handicrafts, at which many display great skill. Practically all the patients who are up do some gardening, clerical work, or tasks in the wards. Singing and dancing classes, entertainments arranged by the patients themselves, parties and picnics keep the patients cheerful and happy. The consultant staff includes a general surgeon, an ophthalmic surgeon, a gynæcologist, a surgeon for diseases of the ear, nose, and throat, and a dental surgeon.

The steadily increasing waiting list and the results of the treatment are sufficient proof of the need for other hospitals such as this. Systematic investigation into after-histories is carried out three months after discharge and then annually, and these statistics will become valuable material later on. The medical superintendent remarks on the party held last January of about 100 ex-patients, and the almost incredible contrast between the health of the guests then and the memory of what it had been at their worst when they were patients. The most urgent need now is for an associated convalescent home where recovering cases can be treated less expensively under the same general supervision.

## THE QUARTERLY REVIEW OF BIOLOGY.

THERE are, says Prof. Raymond Pearl in the preface to the first number of this new paper, about 25,000 reputable scientific journals in the world to-day, and the promoters of *Biological Abstracts* judge that they will deal with some 4000 journals devoted to their sections of natural knowledge. It sounds almost hopeless to expect that more than a fraction of these printed researches will ever be assimilated, brought into their proper relationships, and made adequate use of. It seems as if we need a group of students who will forswear the fun of exploration for laborious lives of reading, contemplation, and synthesis. Till Mr. Rockefeller endows the appropriate colleges we must get what help we can from such papers as *Physiological Reviews*, *Science Progress*, *Nature*, and the present specialised biological quarterly. Biology moves fast nowadays, and it is of real importance that medical men should have such means as can be provided for keeping themselves aware of what is being done; for medicine is a branch of biology, it has much to receive from general biology, and it has much to contribute from its own unique experience; man is studied on a far greater scale and in much more detail than any other animal. We welcome, therefore, this attempt to make some of the modern developments of biology available for the ordinary reader. It is edited by Prof. Raymond Pearl and R. W. Hegner, of Johns Hopkins University, the form is tolerably agreeable, and the difficulty of reading the long lines of a quarto page is obviated by printing in double columns. The articles in this number deal with the mammalian testis and scrotum, symbiosis among animals, especially termites, experimental morphogenesis of the nervous system, the influence of the length of daylight on the growth of plants, recent work on the amœba and adaptation; there are as well notices of recent biological books.

## HERPETOMONIASIS.

STUDIES [1] carried out by Dr. Jaroslav J. Drbohlav in the Department of Comparative Pathology at the Harvard Medical School serve to clear further the ground for the consideration of the probable, and peculiar, rôle of *Phlebotomus* species in the transmission of human leishmaniasis. Wenyon, investigating Oriental sore in Bagdad in 1910, found a herpetomonad in a *Phlebotomus*, and recent work by others has, at least, gravely implicated this fly as the vector of kala-azar and Oriental sore. Laveran and Franchini (1913–20) reported the successful inoculation of certain insect and plant flagellates into laboratory animals. They concluded that a relationship existed between the herpetomonads of insects and leishmaniasis. Fantham and Porter (1914–15) from their own experiments went further in claiming that leishmaniasis is herpetomoniasis of almost general insect origin, and especially that canine kala-azar is herpetomoniasis due to *Herpetomonas ctenocephali*, a flagellate occurring in the dog-flea. This flea was claimed by Basile (1912) to be the specific host of *Leishmania infantum*. About 115 species of herpetomonads have been reported, 96 of them in insects and arachnids. If the conclusions of Fantham and Porter be accepted, then flagellates from various insects should produce infections in mammals similar to, if not identical with, the leishmaniasis that occurs spontaneously. A considerable number of other investigators experimenting with the same species of flagellates, injecting them in the same way into the same or other similar species of animals, obtained negative results. The results of Drbohlav's work are in entire agreement with these investigators—viz., Wenyon, Novy, Macneal, Torrey, Bruce, Chatton, Delanoe, Rodhain, Pons, V. d. Branden Bequaert, Nöller, Tyzzer, Walker, Patton, Sundara Rao, Glaser, and Becker.

Inoculation of *Herpetomonas ctenocephali* of the dog-flea, from both old and freshly isolated cultures, into warm- and cold-blooded animals was invariably unsuccessful in Dr. Drbohlav's hands. The parasites rapidly degenerated and diminished in number, few could be found after six hours, and none after 24 hours. Up to three hours the parasites could usually be recovered in culture. Crithidia from the water strider, *Gerris remigis*, inoculated into mice, rats, and frogs gave negative results. The inoculated flagellates disappeared in six hours. *Herpetomonas muscarum* from the gut of *Lucilia* genus, and from freshly isolated cultures, inoculated into mice, rats, and frogs, and the same monkey as that used for (unsuccessful) inoculation of flea flagellates, produced no infection. Several species of plants of genus *Euphorbia* and a species of *Asclepias* were all found free from flagellates. In hanging-drop preparations from these Euphorbiaceæ inoculated with *Herpetomonas ctenocephali*, *H. muscarum*, *Leishmania infantum*, and *Trypanosoma rotatorium* motile forms were present after five days; but there was no multiplication and all forms degenerated and were dead after six days. The Euphorbiæ were inoculated with different cultures of herpetomonad flagellates, but no forms were found in the latex. In no animal or plant inoculated was there any sign of multiplication of the above flagellates; in fact these decreased in number and vanished after a few hours. The positive results reported by others may be explained by a confusion of natural infections with the inoculated, especially since proof such as might be obtained by the isolation in culture of the flagellate inoculated is lacking. Drbohlav's experiments indicate no ætiological relationship between *H. ctenocephali*, *H. muscarum*, *Crithidia gerridis*, and leishmaniasis, thus confirming the results obtained by American and most European investigators.

---

[1] Studies on the Relation of Insect Herpetomonad and *Crithidial Flagellates to Leishmaniasis*, Amer. Jour. of Hygiene, vol. v., No. 5, September, 1925.

Whether a single herpetomonad species may be widely distributed among different species and genera of insect hosts is another question which Dr. Drbohlav set himself to answer, using for this purpose pure cultures and the method of cross infection. His experiments show that fleas may be artificially infected with their natural parasite, *H. ctenocephali*, but not with *L. infantum* (thus disproving Basile's contention), *H. muscarum*, or *C. gerridis*. Larvæ of *Ctenocephalus canis* were artificially infected by feeding them with fæces of infected fleas and with cultures of *H. ctenocephali*. Since such infected larvæ remained infected throughout the larval, pupal, and adult stages, it is probable that the natural infection of fleas is acquired in the larval stage by feeding on infected fæces of adult fleas, and not in the adult stage when only animal blood is taken as food. Attempts to infect flagellate-free *Gerris remigis* with *H. ctenocephali*, *L. infantum*, and *C. gerridis* failed. Cross infection experiments with cultures of *H. muscarum* on certain species of the genera *Musca*, *Fannia*, and *Lucilia* gave positive results, all of these species serving as suitable hosts. The flagellates described as different species from these various flies represent therefore one and the same organism, *Herpetomonas muscarum*.

## IRON THERAPY IN INFANTS.

THE efficacy of iron in the treatment of infants has been the subject of frequent dispute, and reference to the literature reveals considerable conflict of opinion, apparent or real. American authors have in recent years been almost unanimous in regarding iron as useless in the treatment of infantile anæmias. The basis of this opinion has in most cases been the result yielded by animal experiment. Dr. Murray Bass and Dr. Bernard Denzer[1] have approached the question from a standpoint which required an ætiological classification of the anæmias before passing judgment on the value of iron. Adopting the continental classification into constitutional, alimentary, and infective anæmias, they draw attention to the different way in which these forms respond to the ingestion of iron, and admit that the third type is not improved by it. The constitutional anæmias include those found in premature infants and twins, and are due to a deficiency of the "iron depôt" posited by Bunge. The alimentary anæmias result from unduly prolonged feeding on milk alone, and consequent exhaustion of the iron depôt. Both these types were found to benefit immediately and unequivocally from the administration of inorganic iron. Some interesting and very convincing case-histories are given as illustrations of the improvement obtained, particularly those of two twins of 1 year who were suffering from severe anæmia of chlorotic type with practically identical blood-pictures. One of them was treated with iron and the other used as a control, their diets being identical. The hæmoglobin percentage of the first rose steadily from 30 to 60 per cent. in six weeks; that of the control remained stationary until transfusion was performed as a necessary life-saving measure. Doubt has been expressed as to the infant's power of absorbing inorganic iron. Experiments referred to in this paper suggest that the administration of iron to a child who is fed exclusively on milk does not bring about an increase of hæmoglobin, but that it will do so if vegetable extract is added to the diet; the fault is not in the absorption of the iron, but in the synthesis of the hæmatin portion of the hæmoglobin.

The views which we have quoted are held by many observers in Europe, especially in France. To a certain extent the conflict of opinion between them and the majority of American authors is more apparent than real. The statement that the great majority of anæmic infants do not benefit by iron is true, because the great majority of them belong to the class in which the anæmia is a symptom or sequela of some infection. In this country there is probably no pediatrist who will decry the use of iron in a primary anæmia of the chlorotic type, but there is a notable divergence of opinion on the frequency of their incidence. It is likely that the comparative infrequency of prolonged breast-feeding in this country may affect the question. There can be little doubt that suitable solutions of inorganic iron are absorbed by the infant's intestinal tract, but it is a common experience that they set up an irritation of that tract, with resulting dyspepsia and anorexia. That this is due to the absorption and not to the excretion of the metal is rendered likely by the fact that these symptoms usually disappear when oral administration is replaced by intramuscular injection. Some excellent preparations intended for the latter method are obtainable, and have added considerably to the applicability of iron therapy.

## THE ATTACHMENT OF THE EXTRA LIMB.

Samuel Butler rightly pointed out that a spade, a typewriter, and a locomotive could be regarded as detachable and artificial limbs. As such they come within the province of medicine, for an inefficient joint or contact between an operator and his machine may affect his health and his efficiency just as much as a diseased articulation between two bones. The efficiency or otherwise of industrial methods may not be the direct concern of medicine, but it is its concern to diminish the damage done by asymmetrical and dysharmonious effort. Physiology is the study of the mechanism of the normal vital processes and the way in which they react to environmental change, and it offers information on the conditions under which work can be done efficiently. It is very desirable that this information shall reach those who have to preserve and increase the health of the public, and that it should be applied in industry. We welcome, therefore, the announcement of a course of lectures, by Prof. R. J. S. McDowall, designed to meet the needs of candidates for the D.P.H., on Physiology as Applied to Hygiene, which was recently announced as beginning on May 7th (vide THE LANCET, April 17th, p. 837). The Industrial Fatigue Research Board and the related scientific committees of the Medical Research Council continue to produce a steady flow of really useful information on the attainment of efficiency. The results already obtained on the comparative physiological cost of muscular work carried out at different speeds and of variations in the position of the load carried, on the influence of rest pauses, and of changes of posture on the capacity for muscular work, and on the extent and effects of variety in repetitive work, are the groundwork of industrial physiology—the groundwork of an immensely important science. It ought to be familiar to hygienists, and it ought to be continued. Only last week an interesting publication was issued by the Board describing an investigation by two engineers, Mr. L. A. Legros and Mr. H. C. Weston, into the Design of Machinery in Relation to the Operator.[1] As an introduction to the report they describe the evolution of the bicycle from a hobby-horse of 1818 to the relatively efficient machine of to-day. In 1840 McMillan fitted a crank-drive to the two-wheeled frame—he combined machine and rider in one mechanism. But the bone-shaker, in use in the 'sixties, necessitated a cramped position for the body and caused suffering to the rider by vibration and jolting on its solid metal tyres, and gradually it had to be modified and improved. At first the modification was mechanical, so as to obtain high efficiency; then it was psychological, so as to reduce the risk of falling and difficulty of balance; and finally it was physiological, so as to reduce vibration and enable the force exerted by the rider to be more efficiently applied. The bicycle, as they point out, has had the advantage of being tested in races, and its effect in producing fatigue has been severely tried. Industrial machines do not receive these direct tests, and it is not unusual for inefficient clumsy models to be reproduced (like inaccurate literary references) through many generations. The evolution of many varieties, moreover, has been impeded by too slavishly copying manual movement. This report does not, perhaps, specially concern medical men except in so far as it illustrates a principle; but the specific improvements which it suggests in various types of machine—notably of those in the laundry and leather-work trades—will be of such help to manufacturers that they will certainly ask for more.

## GLAND-GRAFTING.

GRAFTING of glands is still on its trial. The experiments of Steinach, Voronoff, and others gave ground for hope that a new weapon against hitherto unconquerable diseases was to be placed in our hands. But grafting soon revealed itself as very uncertain. The proportion of grafts that take is not large, and the laws that govern a graft's chance of survival are still imperfectly understood. The vitality even of a slip that seems to have taken hold is open to dispute, and the slip itself always seems to disappear after a short time. No proof has indeed been offered that a graft ever acquires cellular activity of its own, or that its virtue is appreciably greater than so much glandular tissue introduced into the alimentary canal. This being so, the report of Dr. Frugoni and Dr. Scinone, of Florence,[1] on a case of chronic tetanus treated by a graft of human parathyroid into the tunica vaginalis, after the method described by Voronoff, is worth study. No one case can prove a theory or establish a method, but this success will encourage other investigators to take heart. Undoubtedly many experiments which have failed through a bad choice of site for the graft would, if repeated on the lines indicated, give more decisive results.

The patient was 21 years old, electrician by trade, a very heavy smoker. Family history good. At 16, after a heavy meal of plums, he had an attack of acute gastro-enteritis accompanied by a typical tetanic attack—"obstetrical" hands, painful rigidity of the arms with the forearm flexed and the upper arm pressed against the trunk, spasmodic rigidity of the lower limbs, abdominal contraction, difficulty in breathing, opisthotonos, diplopia, and lockjaw. This attack lasted three days; psychic and sensory function remained normal. After five months he had another and thereafter further attacks, at diminishing intervals, up to four in a single night. Between the attacks he sometimes lost consciousness and fell. His constitution was robust, but his general condition was not good; panniculus poor and mucosæ pale. Pulse and respiration regular and intelligence normal; but disposition impulsive and restless. He had a slight exophthalmos, a weak conjunctival reflex, and nystagmus on glancing sideways, with strabismus due to spasm of the internal rectus. Chvostek's sign was well marked; percussion of the facial muscles or of the sterno-mastoids, especially at their insertion, and of the abdominal muscles, would produce lively contraction. Trousseau's sign was actively present. The sign of Lasègue was absent, but if the extended leg were flexed on the pelvis severe cramp overtook all its muscles, especially those of the foot, which showed a hollow sole with the great toe in violent flexion. The attacks were sometimes accompanied by genuine epileptic seizures, with loss of consciousness. The effect of calcium chloride injections was transitory and the most intensive antisyphilitic remedies gave no result. The cause of the deficiency was probably a specific syphilitic lesion. An active gumma or arteritis would hardly have taken so long to produce the effects, nor would it have been so intractable to the ordinary remedies. The operation followed the technique of Voronoff. Under novocaine anæsthesia an incision 7 cm. long was made in the tunica vaginalis, the testicle withdrawn, and the graft fixed on its medial side in the cul-de-sac near the epididymis, fine catgut being used and drawn, not through the glandular tissue, but through the fringe of fat and connective tissue surrounding the gland.

When the operation was performed the patient was undergoing six or seven long and extremely painful attacks every day. The graft effected on June 11th had an almost instantaneous effect. On the next day but one following it took three minutes to provoke the Trousseau sign, which hitherto had appeared at once; two days later the leg would not cramp under flexure and Trousseau's sign had disappeared. It came back from June 16th to 25th, and then vanished for good. Chvostek's sign, although much less conspicuous, was still present up to the date of the report, showing that a slight parathyroid deficiency remained which the graft had not succeeded in compensating. Others have noted this persistence. Meanwhile the patient, released from his pain, picked up amazingly. Excitability tests, taken after 15 to 25 days, showed that while the state of the facial muscles was unaltered, the threshold for those of the arm was considerably raised. Most important of all, the ingrafted gland was felt on palpation firmly attached to the testicle, and at the end of five months it had lost nothing of its volume. Much of the interest of the case depends on how long the graft will survive, but it has served to prove the connexion between chronic tetany and parathyroid deficiency and to demonstrate the advantage of Voronoff's innovation. Even if the hopes of the authors are destroyed by the ultimate disappearance of this, as of most grafts, they have at any rate made a substantial contribution to the resources of gland therapy.

## A REVISED VIEW OF PANCREATIC SECRETION.

ACCORDING to Bayliss and Starling the hormone called secretin which stimulates the pancreas to activity is derived, by the action of acid, from a precursor called prosecretin and therefore exists only in that part of the small intestine where there is acid to promote the change. It is supposed that when the acid contents of the stomach pass into the duodenum they act at once upon the prosecretin present in the walls to form secretin; this is absorbed into the circulation and thus is carried to the pancreas. If this view is correct it is clear that the secretion of pancreatic juice depends to a large extent on the production of hydrochloric acid by the gastric mucosa; but an account of recent investigations of J. Mellanby and A. St. G. Huggett, published in the *Journal of Physiology* (1926, lx., 25), suggests that this explanation does not altogether fit the facts. These workers began by determining the distribution of prosecretin in the alimentary canal, making an extract from the mucous membrane with 0·2 per cent. hydrochloric acid as recommended by Bayliss and Starling. They discovered, however, that hydrochloric acid has no specific capacity for the preparation of secretin extracts from the alkaline mucosa and found that dilute alcohol is in fact much more effective for the purpose than acid. They claim, moreover, that their experiments prove the presence of considerable quantities of pre-formed secretin in the mucous membrane of the upper two-thirds of the small intestine; a relatively small quantity may also be extracted from the lowest third. The secretin contained in the mucous membrane is, they state, soluble in water and is relatively stable in dilute solution of acid or alkali, alcohol, and acetone. It may therefore be obtained by extracting the mucous membrane of the upper two-thirds of the small intestine with water, 0·2 per cent. NaOH, phosphate solutions (pH 7·5, 6·5), 0·2 per cent. hydrochloric acid, 75 per cent. alcohol or 75 per cent. acetone. There is no evidence, they consider, that gastric hydrochloric acid converts a precursor (prosecretin) present in the duodenal mucous membrane into *secretin and thus excites a flow of pancreatic juice,* as was suggested by Bayliss and Starling. Secretin, they remark, possesses all the properties of a secondary albumose, being soluble in water, precipitated on full saturation with $Am_2SO_4$ and destroyed by pepsin, trypsin, and the intracellular enzymes of the small intestine. It is not derived from the alimentary digestion of protein, since it is present in considerable quantities in the small intestine of the fœtus. In conclusion, they find no evidence that the chemical group to which secretin owes its activity is of the nature of a primary amine.

---

## THE FUNCTION OF AURAL CERUMEN.

THE function and purpose in nature of the cerumen secreted by the external auditory canal is a subject which has not attracted much attention from experts. In a recent issue of the *Journal of Laryngology and Otology* (April, 1926), Dr. E. ff. Creed and Mr. V. E. Negus contribute the results of some investigations they have made. Of 60 individuals examined, only five had no cerumen, and all of these had healthy ears. Neither age nor the width of the meatus had any definite effect on the amount, consistence, or colour of the wax; but the tendency was for the quantity to be smaller in the female sex. A bacteriological examination of the cerumen from 49 specimens was made, and in only two cases was there no growth; staphylococci, moulds, and diphtheroid bacilli were the most frequently found organisms. The writers come to the conclusion that cerumen is most decidedly not bactericidal; on the contrary, it serves as a medium in which organisms of great variety may multiply. They suggest that it has no important function in man, and that the only useful function it can *serve is to prevent mechanically* the entrance of such things as dust and insects to the deep meatus. There is, we think, another useful function. As well as making people deaf by occlusion of the meatus, and being a source of trouble, if also of emoluments, to doctors and aurists, is it not possible that it is of service in aiding the removal of shed epithelial débris from the auditory canal? The external auditory meatus is the only example in the body of a deep narrow cavity lined by ordinary skin, which is constantly shedding its outer layers. On the surface the shed flakes are removed imperceptibly, but in the meatus the cerumen forms a lubricant which adds bulk to the desquamation and assists its discharge. In the great majority of cases it performs this function admirably, and the wax comes away in frequent small quantities, which are almost unnoticed. But it is necessary that its consistence should be correct; if it is too stiff it collects and may in time occlude the meatus. Accumulations of shed epithelium in the meatus are not infrequent and are far more troublesome than collections of wax; they may be due, in part at least, to the absence of the secretion.

## THE BOXER INDEMNITY AND PUBLIC HEALTH.

THE funds due under the Boxer Indemnity are to be allocated by the Powers to undertakings for the benefit of China. An earnest appeal to the British Government has been issued by two representative leaders of Chinese medicine, Dr. S. M. Howe and Dr. W. L. New, who suggest that a portion of the sum to be remitted by Great Britain shall be devoted to public health work. The Americans, they remark, have encouraged higher education amongst the Chinese; the French have used their funds partly for financial stabilisation and partly for education; the Dutch have begun a conservancy scheme on the Yellow River; the Japanese intend to spend the money on an Oriental library and research laboratory. As yet the British Government has come to no decision, though a Commission has been appointed. What could be more appropriate, it is suggested, than that Britain should give to China "that part of its culture in which it leads the world"? Modern *industrialism and rapid transport took their origin in* England. The sanitary evils which they brought in their train first appeared in this country, and naturally the British became the pioneers of health legislation. This position they have maintained, but unfortunately, in other lands, the antidote is slow in following the poison. In China industry and communications are making headway, and there has, of course, always been a crying need for hygiene and sanitation. We publish on page 946 some account of the present situation, and it is satisfactory to note the rising standard of medical education. But public health work in China is still hardly more than sporadic, and the tasks to be faced are stupendous. Dr. Howe and Dr. New, who speak for the two principal medical organisations of China, suggest that as an initial step a Public Health Commission should be set up. According to their proposal this would involve the use of £100,000 per annum, which is less than a quarter of the sum to be remitted by the British Government. The function of the Commission would be to encourage the attempts of provincial and local city governments to inaugurate health measures, and to give them technical direction. In the past little result has followed municipal schemes because the officials have had a wrong outlook on public health and because there has been a lack of funds and coördination of the existing facilities. Certainly even a relatively small sum, judiciously expended, has been known to act as catalyst in a large public health movement. A Commission could secure the local appropriation of funds by offering partial support over an initial period of years and could lend out medical personnel while local officials were being trained abroad. On these lines, it is clear, much good might be done. "We are confident," *says the appeal,* "that no other expenditure on such a small scale could be made to affect within a decade the welfare of as many persons as the plan proposed." Plague, cholera, small-pox, and typhus cause appalling havoc in China, and their control can only be hoped for if schemes of preventive medicine are begun.

MR. Guy Capper Birt, M.R.C.S., L.R.C.P. Lond., L.D.S., has been appointed surgeon-dentist to His Majesty the King, in the room of Sir Harry Baldwin, C.V.O., who has been appointed honorary surgeon-dentist to His Majesty.

BY an Order of the Committee of Privy Council, Lieut.-General Sir William B. Leishman, Director General, Army Medical Services, has been appointed a member of the Medical Research Council. The vacancy thus filled was consequent upon the recent approval of amendments to the Royal Charter of the Medical Research Council, which provide, inter alia, for an increase in the number of members from 10 to 11. Under the amended Charter, two of the eight scientific members will retire in each year, and one of the three other members in each second year, the scientific members being not eligible for reappointment before the end of one year after retirement.

---

WILLIAM NICHOLLS CONVALESCENT HOME.—A convalescent home in connexion with Cardiff Royal Infirmary was opened on April 24th by Lady Nicholls, the wife of the donor. The house, formerly known as Ty-to-Maen, was built by the late Mr. Richard Allen, and his nephew, Sir William Edgar Nicholls, has presented it to the Infirmary as a memorial to his uncle. Thirty-five convalescent patients are already installed in the home, which has beautiful grounds. It is situated at St. Mellons, about midway between Cardiff and Newport. Lady Nicholls has presented a wireless installation for the use of the patients in the home. Among the speakers at the opening ceremony, which was largely attended, was Sir Ewen Maclean. He drew attention to the urgent need for more hospital beds in Wales, where there were only two general hospital beds to every 1000 of the population.

# Modern Technique in Treatment.

## CLXXI.—THE TREATMENT OF DIABETES.

### I. DIETETIC TREATMENT.*

THE aim of treatment of a patient with diabetes mellitus, whether dietetic measures alone are used or whether insulin therapy is added, is to contrive that the blood-sugar before breakfast is within the normal limits of 0·08 to 0·13 per cent.; that it does not exceed 0·18 per cent. at any time of the day, and is not raised above 0·15 per cent. for more than two hours after a meal. The proportion of carbohydrate, protein, and fat should be such that either no acetone bodies or only minimal amounts appear in the urine. The caloric value of the diet should be sufficient to enable the patient to maintain his weight, lead his ordinary life, and, if a child, to grow and develop properly. The urine which is passed after the evening meal should be tested for sugar. Benedict's qualitative solution should be used in preference to Fehling's solution as it is easier for the patient to learn. The general health of the patient must be cared for and minor complications, such as constipation and any form of focal sepsis, must receive the appropriate treatment.

### *Dietetic Measures.*

The normal diet may be altered in either of two ways: (1) by a reduction in its caloric value to about one half the normal amount and a careful balancing of the carbohydrate and fat to prevent ketosis—the so-called maintenance diet; (2) by ordering a short fast, to be followed by a rapid increase in the diet to the same level as the maintenance diet—the ladder diet. Both methods have their adherents and merit discussion.

### *The Maintenance Diet.*

The maintenance diet was introduced in America as a reaction from prolonged fasts and severe undernutrition and partly to prevent any ketosis. It is useful in dealing with patients who have already been under treatment for diabetes. In the hands of physicians specially experienced in the management of diabetic patients it gives excellent results even in new cases, though for the reasons set out below I personally prefer the ladder diet for these.

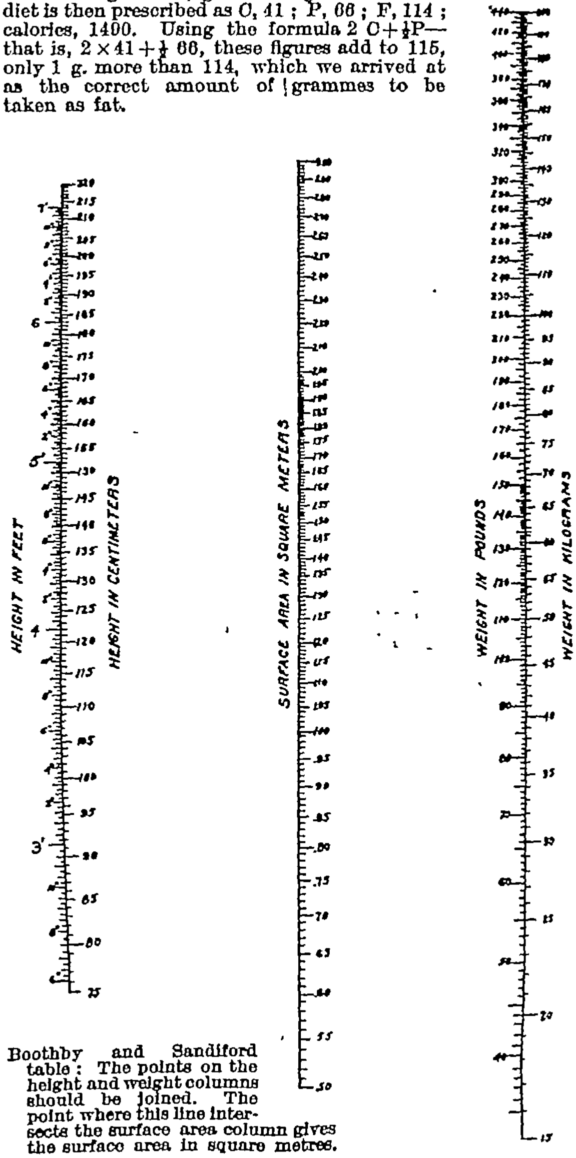
In order to construct the maintenance diet certain calculations are necessary.

The patient's body-weight and height are ascertained, and using the Boothby and Sandiford table (see figure) the surface of the body in square metres is read off. Example: Height, 63 in.; weight, 132 lb.; surface area, 1·62 sq. metres. If the patient is a male aged 40, the calories required for the metabolism, while at rest in bed, are read off from the Aub-Du Bois table. In this case it is 924 per sq. metre, or 1497 per 1·62 sq. metre. This amounts to 11·3 cals. per pound. If this calculation is impossible an approximate result can be obtained by multiplying the patient's weight—132 lb.—by 11·3 = 1492. In our example the result is practically identical, and although this is not always the case the error will never be very great.

In order that the diet may be correctly balanced it must fulfil the following conditions. The number of grammes of fat must equal the sum of twice the number of grammes of carbohydrate and half the number of grammes of protein. This is best expressed as an equation. $F = 2\,C + \frac{1}{2}\,P$.

The caloric value to be given—in this case 1490—is then divided between the carbohydrate, protein, and fat in the following way.

For an adult ½ g. of protein is allowed per 1 lb. of body-weight; in this case the allowance amounts to 66 g. This figure multiplied by 4·1 (caloric value of protein) gives 270 calories from the protein and leaves 1220 for division between the carbohydrate and fat. In order to prevent any ketosis the balance between these two must be carefully struck. If the caloric value (1220) still available is divided by the arbitrary figure 30 the quotient is the amount of carbohydrate to be consumed per day in grammes—in this case 41. This figure multiplied by 4·1 (caloric value of 1 g. carbohydrate) gives 168 calories. 1220 minus 168 leaves 1052 calories for the fat, and this number divided by 9·3 (the caloric value of 1 g. of fat) gives 114 g. of fat. The diet is then prescribed as C, 41; P, 66; F, 114; calories, 1400. Using the formula $2\,C + \frac{1}{2}P$—that is, $2 \times 41 + \frac{1}{2}\,66$, these figures add to 115, only 1 g. more than 114, which we arrived at as the correct amount of grammes to be taken as fat.



Boothby and Sandiford table: The points on the height and weight columns should be joined. The point where this line intersects the surface area column gives the surface area in square metres.

AUB-DU BOIS TABLE.—*Caloric Requirement per Square Metre of Body Surface.*

| Age (years). | Cal. per day. | | Age (years). | Cal. per day. | |
|---|---|---|---|---|---|
| | M. | F. | | M. | F. |
| 10–12 | 1236 | 1200 | 20–30 | 948 | 888 |
| 12–14 | 1200 | 1116 | 30–40 | 948 | 876 |
| 14–16 | 1104 | 1032 | 40–50 | 924 | 864 |
| 16–18 | 1032 | 960 | 50–60 | 900 | 840 |
| 18–20 | 984 | 912 | 60–70 | 876 | 816 |

M. = males. F. = females.

Calculate requirement in children according to weight. Up to—

| | |
|---|---|
| 22 lb. .. .. .. .. .. | 27·5 cal. per lb. |
| 22–33 lb. .. .. .. .. .. | 25·0 „ |
| 33–44 lb. .. .. .. .. .. | 25·0 „ |

The total amount of calories to be consumed in the day—in our hypothetical case, 1400—is divided into four meals of approximately the following amounts: Breakfast: C, 18·5; P, 22; F, 38; calories, 490. Midday: C, 9; P, 15; F, 25; calories, 330. Tea: C, 5; P, 7·5; F, 12; calories, 103. Evening: C, 18·5; P, 22; F, 38; calories, 490.

* Part II., on the Insulin Treatment of Diabetes, will appear in THE LANCET next week.

### *How to Use this Diet.*

In order to use this diet reference must be made to diet tables such as those of Poulton[1] and Harrison and Lawrence,[2] for it is essential to give variety. Some patients learn to calculate their diet very accurately with these tables, but the majority need another method. A simpler way has been devised by R. D. Lawrence,[3] who has calculated the amounts of protein and fat in the following dishes and made these approximately equivalent to each other by adding different amounts of fat.

The following articles of food contain approximately 7·5 g. protein and 15 g. fat: Bacon, 1 oz. Ham, tongue, or sardines, 1 oz., with ¼ oz. fat. Cheese, ¾ oz., with ¼ oz. fat. One egg or salmon, 1 oz., with ⅜ oz. fat. Lean beef, mutton, lamb, veal, pork, chicken, or liver, 1 oz., with ⅓ oz. fat. Pheasant, grouse, partridge, or rabbit, ¾ oz., with ½ oz. fat. White fish, crab, lobster, 1¼ oz., with ⅝ oz. fat.

In order to know how many of these rations should be eaten in the day the amount of protein to be consumed is divided by 7·5. In the case we have been considering, where the patient was allowed 66 g. of protein, he would get approximately nine rations. Of these, three rations are eaten at breakfast, two at midday, one at tea, and three at the evening meal. The total fat in these nine rations is 135 g., or 20 g. more than is allowed in our example. In order to correct this four-fifths of an ounce of fat must be deducted from the fat ration.

The carbohydrate ration is worked out separately because the daily carbohydrate ration allowed for in the maintenance diet should, in my opinion at least, only be reached by stages. At the outset of treatment, when the patient is still passing sugar, only 20 g. of carbohydrate are given.

5 g. of carbohydrate are contained in approx. 5 oz. of the following vegetables: asparagus, broccoli, cauliflower, brussels sprouts, celery, cucumber, endive, French beans, leeks, lettuce, vegetable marrow, rhubarb, spinach, tomato, sea kale, turnips, Jerusalem artichoke.

5 g. of carbohydrate are contained in: apple, 1 oz.; apricot, 1½ oz.; banana, ¾ oz.; blackberries, 1¾ oz.; black currants, 1¾ oz.; cherries, 2¼ oz.; damsons, 3¼ oz.; gooseberries, 2½ oz.; greengage, 1½ oz.; grape, 1 oz.; grapefruit, 2 oz.; Brazil-nuts, 2¾ oz.; hazel-nuts, 1½ oz.; walnuts, 1½ oz.; oranges, 1¾ oz.; peaches, 8 oz.; pears, 1½ oz.; boiled peas, 1½ oz.; plums, 1½ oz.; raspberries, 1½ oz.; red currants, 1½ oz.; strawberries, 2¼ oz. (Harrison and Lawrence.)

The carbohydrate is kept at this level (20 g.) until the urine is sugar-free and the blood-sugar normal. As soon as this occurs the carbohydrate is increased by 5 g. portions until 40 g. are reached, at which stage there should be no acetone bodies in the urine. If this is not the case the carbohydrate must be again increased. If, on the other hand, the urine does not become sugar-free on 20 g. of carbohydrate per day, insulin treatment is called for.

### *The Ladder Diet.*

The ladder diet is in many ways simpler than the maintenance diet. Moreover, I prefer the principle of the preliminary short fast for the following reasons: (1) Symptoms are relieved at once, and in many cases the blood-sugar falls to normal in two or three days. (2) It has a valuable psychological effect; every addition to the diet is appreciated and a scale of half rations, such as the maintenance diet, which seems meagre except after a fast, is tolerated. A fast day is less tiresome than a half-ration day. (3) The fast day also has a use in that the patient starts the treatment with a period in bed and is more willing to treat his condition seriously. Three to four weeks should be devoted to the preliminary treatment so as to give the beta cells of the islands of Langerhans the best chance of recovery and to enable the patient to learn the details of the new diet and get accustomed to the change. It is suitable without variation for an adult of about 130 lb., but must be somewhat reduced for children and young adults.

On the fast day as much fluid as is desired may be taken—tea, coffee (with no milk or sugar), gravy soup or meat extract, fresh lemonade sweetened with saccharine.

*Diet 2.*—The fast is broken by a modification of the von Noorden egg and vegetable diet. Breakfast: two eggs, ½ oz. butter, 2 oz. of lettuce or tomato, tea or coffee. Midday: one egg, 6 oz. of green vegetables (5 per cent. group), ½ oz. butter, 10 oz. gravy soup. Tea: two eggs, ½ oz. butter, 2 oz. of salad, tea or coffee. Supper: 6 oz. of green vegetables, ½ oz. of butter, 10 oz. of gravy soup. One ounce of cream is taken in the tea and coffee. Carbohydrate, 17·5 g.; protein, 38·5; fat, 58·5; calories, 778. If the patient does not like eggs, an equivalent amount of meat or fish can be substituted, using diet tables.

*Diet 3.*—2 oz. of meat are added to the midday meal: C, 17·5; P, 52·8; F, 72·5; calories, 968.

*Diet 4.*—2 oz. of bacon are added for breakfast and the egg at midday is deducted: C, 17·5; P, 56·6; F, 97; calories, 1208.

*Diet 5.*—3 oz. of ham or other meat or equivalent of fish are added for the evening meal and one egg is deducted: C, 17·5; P, 59·2; F, 112; calories, 1360.

*Diet 6.*—4 oz. of milk are added as desired: C, 24·5; P, 64·3; F, 117; calories, 1450.

*Diet 7.*—5 g. of carbohydrate in the form of fruit are added: C, 29·5; P, 64·3; F, 117; calories, 1470.

If the patient has responded well to the diet the blood-sugar will be normal and the urine will only contain a trace of acetone bodies. If not, then insulin will be required. This level of diet is nearly the same as the maintenance diet, but the carbohydrate allowance is a little lower. The carbohydrate can be cautiously increased each week until it reaches 40 g.

### *Total Amount of Food.*

In both schemes the next step is to determine the total amount of food which the patient needs. Some patients need very little food and gain weight on very low diets; others require a very big increase in the diet before they gain weight. The test of whether the diet is adequate is the weighing machine, and the patient should be weighed each week. If the patient's weight is much below the normal for age and sex the diet must be increased each week by 50 or 100 calories. In order to keep the balance right the increase should be made in the proportion of 12 g. protein to 6 g. fat (½ P = F). If the patient exceeds the normal weight for the age and sex the diet must be decreased. While this is being settled the patient should be instructed how to vary the diet. The carbohydrate ration is best taken in the form of milk, vegetables, and fruit, since the most variety can be obtained in this way. Some patients crave so much for bread that it is necessary to allow some in the form of toast. The protein can be varied by using any kind of meat, fish, cheese, or eggs. Their composition must be worked out approximately from diet tables, but it is unnecessary to be too meticulous in considering whether the meat comes from the undercut or topside of beef. The margin of error in the cooking is so large that these differences need not be considered. The fat can be taken as butter or cream. The real deprivation comes from the lack of an appetising bread substitute to eat with meals. In proportion as the bread substitute contains less starch so it becomes less palatable. Many preparations which are supposed to be suitable for diabetics contain a considerable amount of starch, even up to 40 per cent. No diabetic food should be eaten whose percentage composition is not clearly stated. It is an advantage to have the amounts of C.P.F. set out in terms of 1 oz., as this permits the patient to make the substitutions for meat and eggs easily. The special diabetic foods should not be taken in addition to the diet unless the caloric value is being intentionally increased. Diabetic jellies, jams, and preserved fruits all contain glycerine which is burnt as sugar, and must be calculated as a part of the carbohydrate ration.

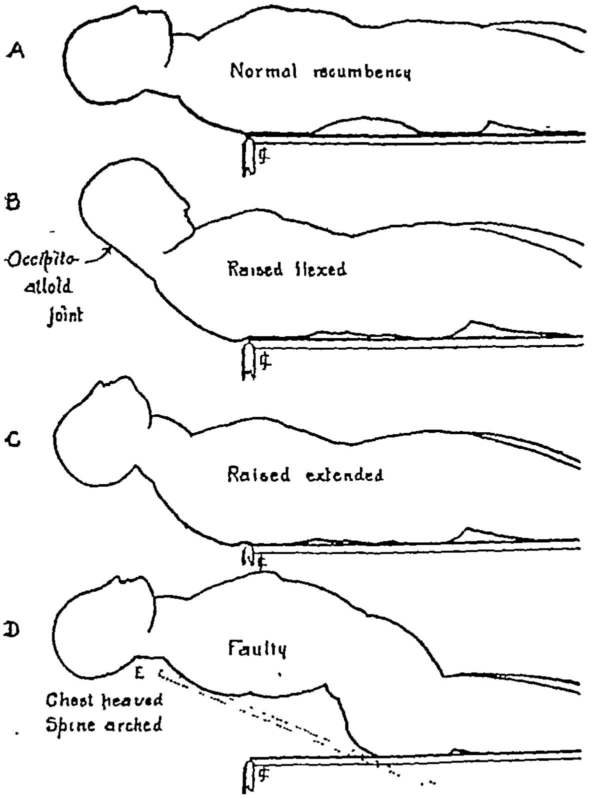
## THE TECHNIQUE OF PERORAL ENDOSCOPY.

BY CHEVALIER JACKSON, M.D., Sc.D.

*(From the Bronchoscopic Clinic, University Hospital, Philadelphia, Pa.)*

IN presenting here, in response to a request, a description of the technique used at the Bronchoscopic Clinics of Philadelphia, I have no thought of urging others to adopt any of the methods we use here. It seems necessary to state our reasons in connexion with some of the details; but these reasons, cogent to us, may not appeal to others. In this field, as elsewhere, every operator should decide all questions in relation to his patient as an equation in which the given terms are the operator, the available armamentarium, and all the various features of the particular case under consideration. The latter will include the age and condition of the patient, the presence or absence of secretions and secondary pathology, the mechanical problem, and especially the presence or absence of dyspnœa.

FIG. 1.



Schema of position for endoscopy. A. Normal recumbency on the table with pillow supporting the head. The larynx can be directly examined in this position, but a better position is obtainable. B. Head is raised to proper position with head flexed. Muscles of front of neck are relaxed and exposure of *larynx thus rendered easier*; but for most endoscopic work a certain amount of extension is desired. The elevation is the important thing. C. The neck being maintained in position B, the desired amount of extension of the head is obtained by a movement limited to the occipito-atloid articulation by the assistant's hand placed as shown by the dart (B). D. Faulty position. Unless prevented, almost all patients will heave up the chest and arch the lumbar spine so as to defeat the object and to render endoscopy difficult by bringing the chest up to the high-held head, thus assuming the same *relation of the head* to the chest as exists in the Rose position (a faulty one for endoscopy), as will be understood by assuming that the dotted line E represents the table. If the pelvis be not held down to the table the patient may even assume the opisthotonos position by supporting his weight on his heels on the table and his head on the assistant's hand. (From a drawing by the author.)

### *Drill.*

We study all these factors but our procedure is always the same, and every member of the team is drilled for months in the steps. If the case is a difficult and dangerous one every member of the team is going through the same old routine and confusion is avoided. If the case is an easy one no harm has been done by our excess of preparedness. The object of drill in an army is not for purposes of parade. Its fundamental advantage is that when anything is to be done it will be done with promptness and precision. Without drill the army would be a mob. In endoscopic work, especially with babies, who constitute the majority of foreign body cases, serious emergency cases will come to the operator, and lack of the promptness and precision which only drill can give will surely increase the mortality-rate of the clinic. Fortunately, the widespread development of bronchoscopy and œsophagoscopy for the diagnosis and treatment of disease affords abundant opportunity for the drilling of an organisation on adult patients without risk, while at the same time these patients are receiving benefits that alone fully justify the procedures.

### *Anæsthesia.*

We do not use general anæsthesia for any endoscopic procedure. The chief reason is that we think it is dangerous in certain cases, and needless in any case. Since we are accustomed as a routine to work without it, the work upon a patient in whom the use of general anæsthesia would probably be fatal is an everyday matter of the same old routine, involving no unusual procedure. Most of the deaths during endoscopy under general anæsthesia are due to mechanical obstruction of the airway, usually in a patient dyspnœic beforehand. It is accepted that the risks of general anæsthesia in the general run of surgical work are so slight as to be negligible. It is also accepted that safety in general anæsthesia depends upon an unobstructed airway, the maintenance of which is the anæsthetist's chief duty. In endoscopic work, laryngeal, tracheobronchial, or œsophageal, the airway to the lungs is often obstructed, either by the lesion, the foreign body, or the manipulations. The obstruction of the airway can reach a degree productive of deep cyanosis or even arrest of respiration without the slightest danger, if no general anæsthetic is being used, because the moment the airway is cleared respiratory movements return, or if they do not, intermittent pressure on the chest will promptly start them. Respiratory arrest in an anæsthetised patient is always a dangerous condition. More deaths on the table have occurred from general anæsthesia for œsophagoscopy than from that for bronchoscopy because of compression stenosis of the trachea caused by the crowding forward of the "party wall." Foreign bodies at the bifurcation may shut up both bronchi. Laryngeal foreign bodies and lesions cause extreme dyspnœa. The diagnosis of diphtheria of the larynx when no membrane exists in the fauces, in children too young for mirror examination, can be made only by direct laryngoscopy. It requires but a moment to take a diagnostic look at the larynx, and to get a swab specimen, in any child with croupy cough. We feel that the laryngologist should be able to look at the larynx of a croupy baby without anæsthesia, general or local, otherwise the practitioner will not avail himself of this diagnostic procedure. The unusual degree of bronchial expansion accompanying the deep inspiration that follows cough, when no anæsthetic is used, has been of the greatest aid to us, by opening up forceps spaces in cases of tightly fitting foreign bodies. The foregoing is not an effort to persuade anyone to work without anæsthesia. Everyone should do as he thinks best. It has seemed necessary for us to give our reasons for working as we do.

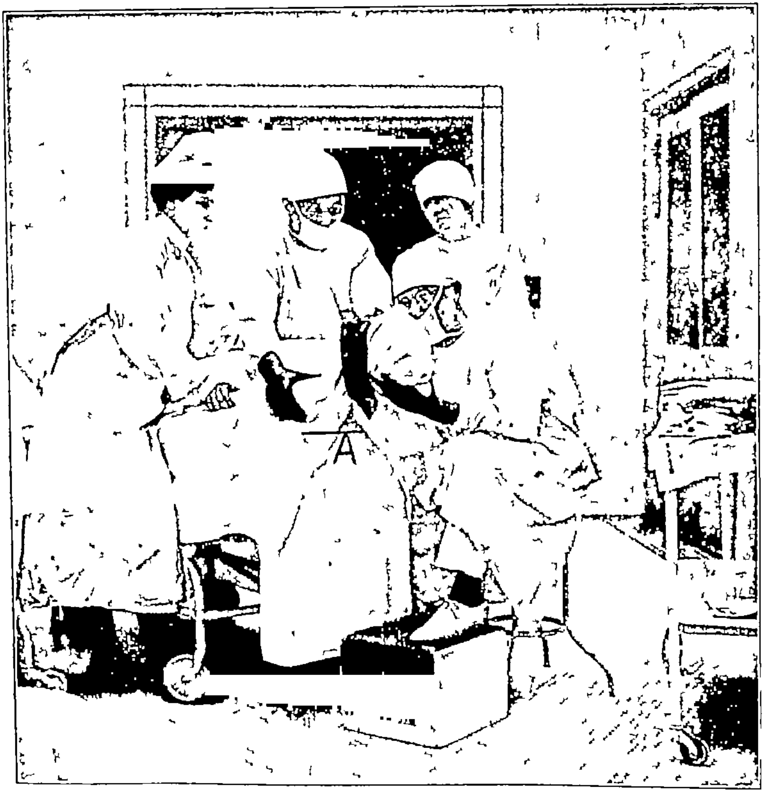
Our custom in regard to anæsthesia may be summarised as follows.

1 No anæsthetic, general or local, is used for œsophagoscopy in either adults or children

2 No anæsthetic, general or local, is used for any endoscopic procedure in children

3 In adults, for direct laryngoscopy and for bronchoscopy, the first few times, cocaine solution is applied to the pharyngeal mucosa in the region of the superior laryngeal nerves with two curved applicators used simultaneously If bronchoscopy is to follow the direct laryngoscopy cocaine solution on a bronchial applicator, or from an atomiser, is sometimes applied through the larynx, but in most cases endobronchial application is deferred until the bronchoscope has been inserted, and it may then be omitted

FIG 2



Position of patient and assistants for introduction of the bronchoscope and œsophagoscope. The middle of the scapulæ rests on the edge of the table the head and shoulders free to move, are supported by the assistant, whose *right* arm passes under the neck the *right* middle finger inserts the bite block into the *left* side of the mouth. The *left* hand, resting on the *left* knee maintains the desired degree of elevation extension, and lateral deflection required by the operator The patient's vertex should be 10 cm. higher than the level (A) of the top of the table. It is essential for the assistant to have constantly in mind that the *right* forearm must not support the neck, all the support must be of the head only and must come from the *left* hand. This is the Boyce position, which has never been improved upon for bronchoscopy and œsophagoscopy, but for satisfactory results every detail must be precisely adhered to

4 As a sedative, morphine, sometimes combined with hyoscine or atropine, is usually given for the first bronchoscopy to lessen apprehension and diminish reflexes. Sedatives are not ordinarily used for œsophagoscopy, though there is no objection to their use

5 If repeated bronchoscopies are necessary, as in the bronchoscopic aspiration of pulmonary suppurations of other than foreign body origin, the sedative and the cocaine are diminished in dosage and are soon omitted altogether in most cases.

### *Position of the Patient*

We always put the patient in the recumbent position The head is held high above the level of the table and the shoulders are held down on the table (Fig 1) The trunk must be controlled to avoid the arching of the spine, as in opisthotonos The knees are held down on the table. The foregoing refers to work in the larynx and to the starting of the tube downward in bronchoscopy and œsophagoscopy As the tube goes downward the head is lowered as required by the operator in order for him to follow by sight the lumen of the trachea, bronchi, or œsophagus. Exposure of the orifice of the middle lobe bronchus requires a very low head; so does the passage through the lower third of the thoracic œsophagus and the abdominal œsophagus; so also does exploration of the stomach. In endoscopic work in the lower œsophagus and stomach relaxation of the diaphragm and abdominal muscles is favoured by flexion of the knees. For direct laryngoscopy the patient's head is held above the table. When the laryngoscopy is preliminary to the introduction of a bronchoscope the patient's head is held out in the air, toward the operator and above the level of the table, the head end of which is dropped (Fig. 3).

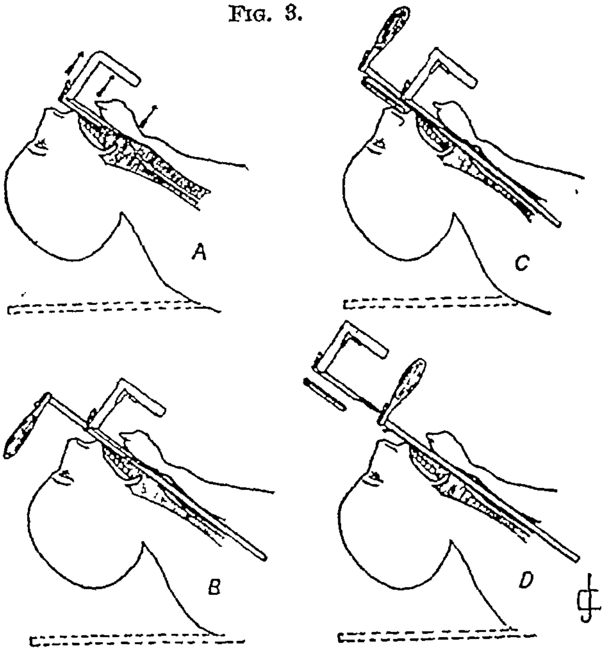
*Direct Laryngoscopy.*—Exposure of the larynx to direct inspection with the patient properly placed and held in the recumbent position is easily done on any patient whose mouth can be opened. Any deviation from the proper position may render it exceedingly difficult. We always use the *left* hand to hold the laryngoscope. This leaves the right hand free for handling laryngeal operating instruments and for the insertion of the bronchoscope without changing hands; and it calls for no greater degree of ambidexterity than the left-handed use of thumb-forceps in dissection, or the left-handed use of the fork while cutting meat on one's plate. It is all a matter of starting right in learning to use the instruments. The coördinate use of the laryngoscope in the left hand and the forceps in the right gives a facility in endolaryngeal operating that seems to us unobtainable with a mechanically held laryngoscope; but we may be biased. Be this as it may, there is no question as to the necessity for left-handed use of the laryngoscope if any degree of facility is to be acquired in bronchoscopy.

The laryngoscope is introduced back along the dorsum of the tongue and the tip of the epiglottis is exposed to view. The lip of the laryngoscope is inserted beyond the proximal edge of the epiglottis for a distance of not more than 1 cm. in a child or 2 cm. in an adult. Then a powerful lifting motion, sufficient to sustain the weight of the patient's head, is imparted to the laryngoscope in the direction of the dart shown at A, Fig. 3. At this point particular care to keep the patient's shoulders down on the table is necessary. Prying on the upper teeth as a fulcrum must be avoided. The patient not being anæsthetised, there will be no glottic chink until he takes a deep breath. If the patient is 3 years of age or over he is told to take a deep breath. If he is under that age he will soon do so without being told.

*Insertion of the Bronchoscope.*—Once the vocal cords are exposed with the direct laryngoscope held in the left hand the insertion of the bronchoscope is easy. The bronchoscope, illuminated with its own lamp, is passed to the operator in exactly the proper position for insertion (point forward, "handle" to the right). The operator, after inserting the bronchoscope in the laryngoscope, transfers his eye to the bronchoscope, and, making sure of the presentation of the vocal cords, insinuates the slanted end of the bronchoscope carefully between them. The exploration of the tracheobronchial tree is a matter of following the lumen, and is greatly facilitated by the position above described, which leaves the head of the patient free to be moved about widely in every direction.

*Introduction of the Œsophagoscope* calls for the exact position of the patient described above. With the œsophagoscope vertical the operator finds the right pyriform sinus by sight, no mandrin being used. Passing downward, the first obstacle is found at the bottom of the hypopharynx, in the rigid contraction of the cricopharyngeus muscle. It is necessary to wait for this to relax, but while waiting continuous *gentle* advancing pressure must be maintained and at the same time the œsophagoscope must be pressed anteriorward by the left thumb, to lift it away from the posterior weak point, where it otherwise is almost certain to perforate. This must be done without lowering the head of the patient. The "handle" of the œsophagoscope is not grasped in the hand. It must be up, by which we know the lip of the tube-mouth is anterior and away from the danger point. The general direction of the entire œsophagoscope is maintained by aiming for the median line as indicated by the midline of the sternum, notwithstanding the fact that we are starting from one side, in the right pyriform sinus. The opening of the lumen is watched for in the *anterior* part of the field. The relaxation of the cricopharyngeal pinchcock is usually accompanied by a regurgitation of saliva, and the slanted end of the tube-mouth glides over anterior to the relaxing cricopharyngeus muscle. Exploration of the thoracic œsophagus is simply a matter of following the lumen as it opens up ahead, a procedure easy of accomplishment when the head is held in the air, free to be moved in every direction, as indicated above. At the hiatus œsophageus the œsophagus goes through the diaphragmatic pinchcock. Just as the rubber tube of a curette is pinched tightly shut by the spring clip known as a pinchcock, just so we have the œsophagus pinched together at the hiatus by the crura and the muscular fibres of the diaphragm. The point in the lumen of the œsophagus corresponding to this pinchcock closure is found by lowering the patient's head to the right and aiming the œsophagoscope (or gastroscope) for the anterior superior spine of the left ilium. Gentle but continuous pressure on the proper place will be rewarded after a few moments of patient waiting by the relaxation of the pinchcock. The opening of the hiatal constriction is usually accompanied by a rush of gastric fluid, which will be clear if the stomach is "empty" and normal; otherwise it may be mixed with pus, blood, or food. Once the hiatus is passed the œsophagoscope slips so quickly and easily through the abdominal œsophagus that the existence of an abdominal œsophagus is not realised. There is no constriction of any kind, functional or structural, noticed at the cardia, only a faint difference in colour and a marked difference in the form of the folds.

FIG. 3.



Schema illustrating oral bronchoscopy. The portion of the table here shown under the head is, in actual work, dropped all the way down perpendicularly. It appears in these drawings as a dotted line to emphasise the *fact* that the head must be above the level of the table during introduction of the bronchoscope into the trachea. A, Exposure of larynx; B, bronchoscope introduced; C, slide removed; D, laryngoscope removed leaving bronchoscope alone in position. (The three figures are from Bronchoscopy and Œsophagoscopy. W. B. Saunders Co.)

*Gastroscopy.*—Exploration of the explorable area of the stomach is carried out in the collapsed state with the open tube œsophagoscope by traversing it upward and downward, moving the tube laterally to a new location at the end of each traverse, as with the mechanical stage of the microscope. If desired a lens system may be inserted in the open tube and the stomach inflated for inspection. The greatest obstacle to reaching the pylorus, especially in adults, is the forward bulging of the spinal column. In children it is not very difficult to reach the pylorus; we have removed perorally a number of times foreign bodies jammed in it.

## ROYAL MEDICAL BENEVOLENT FUND AND GUILD.

### THE FUND.

THE annual meeting of this Fund was held on Tuesday, April 20th, when the Committee of Management, in presenting their report for the previous year, were able to show an increase of £1000 in new subscriptions and a larger distribution of moneys. Altogether 559 persons had been relieved, 392 by grants and 167 by annuities. The income derived from subscriptions and donations amounted to £6685, as against £4780 received in 1924, and that from invested property £4790, as against £4343 in 1924. The amount expended in grants was £5371, as against £5001 in 1924, and in annuities £3870, as against £3467 in 1924, making a total distribution of £9241. The total expenditure was £10,549, including working expenses, £1308, of which £80 was spent on furniture for the new office.

#### *Legacies and Special Donations.*

The following legacies were received: Dr. E. Riley, £250; Dr. E. A. Edelsten, £25; Sir Anderson Critchett, £100; Dr. M. G. Evans (in stocks) to the nominal value of £3325; Dr. W. H. Mason, £200; Dr. Bowen Hogg, £300; Miss E. J. Humby, £100; and Sir Rickman Godlee a contingent legacy of £5000. As the invested funds have now reached over £100,000, the legacies received during and after 1925 will be divided equally between the annuity and grant departments, the amount to be spent annually by the grant department not exceeding one half of the average of the legacies received in the previous five years.

Grateful acknowledgments were made in the report of a special donation of £1000 from Dr. W. Tinker; a grant of £525 from the Medical Insurance Agency; sums of £100 from Messrs. Wanders Ltd. and from Prof. T. K. Monro; of £50 from Mr. E. Hurry Fenwick, from Dr. and Mrs. Smyth of Bristol (towards the Christmas gifts), and from a subscriber as a donation, based on two guineas for every year he had practised. This donation was supplemented by a gift of £20 and accompanied by a letter stating: "I have a very guilty conscience for not having supported the most excellent Fund." The total amount received towards the Christmas Gift Appeal was £113 18s. 0d.

#### *Grant Department.*

The demands on this department, said the report, have increased, and an increased income has not been sufficient adequately to meet the urgent applications. Grants are divided into two categories, those of a temporary nature of £5 or under and those of £12 to £40 payable in monthly instalments, and the report regrets the want of money which prevents larger grants from being given. "The Committee feel," the words run, "if the distressing nature of the cases brought before them with the appalling state of poverty and frequently of starvation which investigation proves to exist were more widely recognised, a much more liberal response in the shape of subscriptions and donations would be forthcoming, and without this it will be impossible to continue assistance, even on the present basis.

#### *Annuity Department.*

The funded property now stands in the balance sheet at £103,887, the income realised was £4580, an increase of £237 over the figure for 1924, and £3850 was distributed to 167 annuitants in sums of from £10 to £40. During the year 11 annuitants died. The Committee elected 39 annuitants and in 17 instances the annuities were increased. The Fund is able to grant 20 annuities of £40; 19 of £30; 30 of £26; and 64 of about £20.

#### *War Emergency Fund.*

A full account of the origin and working of this Fund, together with the names of the Committee, was given in the report issued in 1923. During the past year £1778 4s. 2d. has been distributed, the greater part—viz., £1848—for the education of 29 children, and the remainder in grants to six medical officers. There remains a balance of £523 13s., which has already been allocated.

#### *Election of Officials.*

Sir Thomas Barlow, Bt., was re-elected President. Sir Charters Symonds, K.B.E., Hon. Treasurer, and Dr. Newton Pitt and Mr. R. M. Handfield-Jones were re-elected Hon. Secretaries. Mr. George Bethell, who has been secretary for over 20 years, has retired in serious ill-health and has been granted a pension. Mr. Haines Carter was appointed in September last to succeed him.

### THE GUILD.

The Guild gives help to the beneficiaries of the Fund by distributing comforts in the shape of special foods, clothes, and coals, and renders invaluable assistance in coöperating with the Fund in cases where there are children to be educated. The heavy demands which those in extreme poverty make on the Fund unfortunately prohibit the Committee from contributing more largely towards the educational work of the Guild.

Constant and close coöperation is maintained between the Fund and its Guild, whose increasing importance on the educational side is recognised. Those having opportunity of obtaining special terms at schools in the way of foundation scholarships or bursaries, or again, the means of obtaining training for young people of both sexes, are urged in the report to communicate with the secretary of the Guild, for while the parent Fund deals with the aged and the infirm, the vast importance remains of enabling the rising generation to become self-supporting.

The report closed with a tender of "thanks to the hon. auditors, Messrs. Deloitte, Plender, Griffiths and Co., and to the editors of THE LANCET and of the *British Medical Journal* for their readiness at all times to help the Fund, and for publishing monthly reports of the meetings."

### RECENT GRANTS.

At the last meeting of the Committee of the Royal Medical Benevolent Fund 53 cases were considered and £548 was voted to 40 applicants. The following is a summary of some of the cases relieved:—

Widow, aged 47, of M.D. Aberd. who practised in London and died in 1924. Two sons, aged 18 and 14. Eldest is a cadet in Royal Air Force. Youngest at school; fees paid by Officers' Association. Applicant and younger boy have been living on proceeds of sale of practice. She is a medical woman and her chief difficulty arises from lack of work. A special grant of £14 was made by the Fund to meet outstanding rent.

Daughter, aged 50, of M.R.C.S. who practised in Surrey and died in 1889. Was in a home for several years. Latterly has been able to do light work, but had to leave her last employment through ill-health. An emergency grant of £1 was given to tide her over. She has now secured another post.

Daughter, aged 39, of M.D. Irel. who was in the Navy and died in 1897. All money invested in Germany was lost in the war. Applicant has supported herself and her invalid mother, but owing to recent ill-health has not been able to earn enough to keep them. Neither the applicant nor her mother is eligible for a naval pension as her father commuted his pensions and retired three years before he died. An emergency grant of £3 10s. was given. The applicant is a B.A. and is at present seeking some light post: her health is very indifferent.

Widow, aged 94, of M.R.C.S. who practised in Somerset and died in 1867. Up to the age of 75 supported herself by taking in lodgers. She has made her home with friends for the last 20 years, but now is so old and feeble that she requires constant attention. She has the Old Age Pension and £20 from the Lenoup Charity, and we are asked to supplement this to enable her to have an attendant. Rent 10s. per week. Voted £10 in 12 monthly instalments.

Daughter, aged 66, of a surgeon who practised in the Midlands and died in 1875. Applicant and her sister, aged 61, have managed to maintain themselves since their father died, but owing to illness and ill-health are now without money for necessities. The applicant has managed to earn her living as a hosiery machinist until recently and now receives 9*s.* a week disablement benefit. Her sister at present is very ill and in hospital. Voted £12 in 12 monthly instalments. A grant for the sister will be considered later.

Daughter, aged 74, of M.R.C.S. who practised in Wiltshire and died in 1876. She had a school for 35 years and has had to sell it in order to refund money to the estate of her late partner. Nothing left after sale; she hopes to be able to live with a friend who has a small income of £80 per annum. Applicant has secured the Old Age Pension. Fund voted £30 in 12 monthly instalments.

Subscriptions may be sent to the Hon. Treasurer, Sir Charters Symonds, K.B.E., at 11, Chandos-street, Cavendish-square, London, W. 1.

## MINERS' PHTHISIS IN SOUTH AFRICA:

### COMPENSATION CLAIMS.

THE Miners' Phthisis Medical Bureau, Johannesburg, have issued certain recommendations in regard to medical evidence in support of claims for benefits by miners or dependents of deceased miners.

Medical practitioners attendant upon miners who are believed to be seriously ill or dying from miners' phthisis, or from any other disease to which silicosis is believed to be predisposing or contributory, are urged in all cases to have the sputum examined for the presence of tubercle bacilli, if necessary more than once. The sputum should be expectorated by the patient in the presence of the medical attendant and should be examined at an institution where such examinations are made by experts. In South Africa the Government pathological laboratories at Cape Town and Durban and the South African Institute for Medical Research at Johannesburg carry out such examinations free of charge. A miner resident in the area of the Witwatersrand should be sent to the Miners' Phthisis Medical Bureau for examination during life. A complete clinical and bacteriological examination will thus be assured, and also a radiographic examination, if the patient is able to be subjected to the latter. The evidence obtained by either of these procedures may, in a number of cases, enable the Bureau to place the miner in the pensionable stage of miners' phthisis during life, and thus to secure his position and that of his dependents. A miner resident at a distance from the Witwatersrand, who has not been previously certified by the Bureau to have silicosis or tuberculosis, or who has not been proved to be expectorating tubercle bacilli, should obtain, wherever possible, a good instantaneous X ray negative of the chest, preferably on a film. This should be certified by the radiographer to be that of the miner in question.

In the event of death, in cases in which the above steps have not been adopted or have been adopted with inconclusive results, the Bureau suggest that a post-mortem examination should be made of the lungs of the deceased, in order that the exact condition of these organs should be determined. In all post-mortem examinations held within the Union of South Africa upon the body of a miner or ex-miner, if silicosis or tuberculosis is found in the lungs, the Miners' Phthisis Act of 1925 requires that such lungs shall be forwarded to the Medical Bureau for examination. When autopsies are held outside the Union of South Africa, the lungs, certified to be those of the deceased, should be forwarded for examination and report to an expert pathologist, preferably one who is attached to a public institution. A detailed report by the latter upon the appearances found in the lungs should thereafter be transmitted to the Medical Bureau.

A final paragraph urges the need of a post-mortem examination in all cases unless the presence of silicosis has already been certified by the Bureau, or has been definitely revealed by X ray examination during life, and in addition tubercle bacilli have been found in the sputum. An autopsy is frequently the only possible means of deciding whether a slight degree of silicosis, previously incapable of detection, is associated with a condition of tuberculosis. In the experience of the Bureau the result of a post-mortem examination has just as often confirmed an opinion, formed upon clinical grounds during life, as to the presence of silicosis, as the reverse, and the evidence which such an examination affords may thus be of decisive importance in respect of a claim by the dependents of a deceased miner.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

### *Municipal Administration of Dublin and Cork.*

DURING the past few years the control of the local authorities has been suspended in no less than 17 areas in the Irish Free State, and in these areas commissioners are exercising the normal functions of the local authorities. The most important areas so administered are the cities of Dublin and Cork, and it is recognised that in both cases there has been an increased efficiency accompanied by a decrease in the rates. The Local Government (Temporary Provisions) Act, 1923, which empowers the Minister of Local Government and Public Health to suspend local authorities and appoint commissioners, limit such suspension in each case to three years. In the case of both Dublin and Cork this limit is now nearly reached, and it is expected that the Minister will seek further powers by legislation to enable him to prolong the period of administration by commissioners in those two cities, if not elsewhere.

### *Suspect Shaving-brushes.*

Some alarm has been caused in Dublin by the warning given last week by the medical officer of health for the city that a consignment of suspicious shaving-brushes had reached Dublin last winter. Dr. M. J. Russell, in a letter to the papers, states that he has been informed by the medical officer of health for Glasgow that shaving-brushes imported from Czecho-Slovakia are infected with anthrax, and that, in December, two gross of these brushes were consigned from Glasgow to a firm of auctioneers at an address in O'Connell-street, Dublin. This firm is stated to have since gone out of business. Dr. Russell advises anyone who may have bought shaving-brushes at any of the auctions at the address stated to have them destroyed at once. No case of anthrax has yet been notified, but Dr. Russell's warning is very wise.

### *Death of Major-General R. H. S. Sawyer, A.M.S.*

The medical profession of Dublin, as well as his old comrades in the Army Medical Service, will learn with great regret of the death of Major-General R. H. S. Sawyer, C.B., C.M.G., which took place after a short illness at his residence in Dublin on April 23rd. General Sawyer was educated at Trinity College, Dublin, and passed Bachelor of Medicine in 1879. He became a Fellow of the Royal College of Surgeons in 1887, and has been a member of the Council of that College since his retirement from the Service in 1918. He entered the Army Medical Service early in life, and served in the Hill Expedition of 1898, in the South African war, and in the Great War, being frequently mentioned in despatches. He was promoted major in 1893, lieutenant-colonel in 1901, and colonel in 1910. In the European war he was for some time Deputy Director of Medical Services at Boulogne, retiring at the beginning of 1918. Since his retirement he lived in Dublin, where he renewed many old and formed several new friendships. He was a modest, unassuming man, courteous to all, and much liked by those who were privileged to serve under him. He was in his sixty-ninth year, and enjoyed good health until a few weeks ago, when he contracted broncho-pneumonia, to which he succumbed.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *Ultra-violet Rays and Growth.*

Springer and Tardieu, of Paris, have been studying the effects of depriving animals of sunlight and the therapeutic action of ultra-violet rays. A litter of five rabbits born in underground obscurity was kept under observation. At the sixth week three of them—the least heavy and least developed of the five—were irradiated, and this treatment was repeated on about a dozen occasions with increasing dosage. All three at once underwent a remarkable change in their general development, weight, and vitality. The other two rabbits, which were more vigorous and were therefore chosen as controls, were kept without sunlight or irradiation, and showed a steady diminution in growth; their weight became less and less and at last they died paralysed in the hind quarters. Post-mortem examination revealed no definite macroscopic lesion and no sign whatever of rickets. The three rabbits which were irradiated had not been shaved, which proved that a covering of hair does not stop the rays. According to the authors, there are two main factors which have a part in the production and utilisation of the energy of growth, and which may explain the way in which ultra-violet radiation acts. One of these is the osmotic pressure; this regulates the amount of penetration into the body cells of the molecules whose fixation represents the degree of growth activity. The other is the production of intra-organic electricity All the causes which increase the production of organic electricity—and notably ultra-violet rays—increase the phenomena of nutrition and growth. Ultra-violet rays appear to have effects apart from those of light, for they produce ozone and thus promote tissue oxidation, and they also augment the intra-organic electricity and osmotic pressure.

### *A New Treatment for Parkinsonism.*

Three Lille doctors, M. Polonovski, P. Combemale, and Nayrac, have been treating patients with Parkinson's syndrome with N-oxide of scopolamine, a new compound belonging to the group of genalkaloids. The results obtained have been very satisfactory. Much less toxic than scopolamine, this alkaloid has a therapeutic action in every way similar or even better. It has a considerable effect in reducing the troublesome rigidity, muscular hypertonus, tremor, and excessive salivation so characteristic of this condition The doses used were from 2 to 4 mg. daily, and administration could be continued for several months without leading to tolerance.

### *Gastric Ulcers and Foreign Bodies.*

Dr. Victor Pauchet, of Paris, recently operated on two false gastro-duodenal ulcers. One of the patients had swallowed a pin and the other four needles. These foreign bodies were implanted in the coats of the pylorus and remained there for several years. A diagnosis was only made at operation, for radiographic examination did not reveal the foreign body In the first case he found an inflammatory mass in the pylorus produced by four needles shut in the walls of the stomach; in the second there was a pin which had been there for 30 years. The symptoms in both cases were pain and repeated hæmatemesis. Sometimes there were definite crises of pain with periods of freedom just like those met with in ordinary gastric ulcer.

### *Lymphatic Influenza.*

Dr. Rousseau Saint-Philippe, of Bordeaux, has just described a special form of influenza that he has observed in children. It chiefly affects the lymphatic glands, connective tissue, and muscles of the cervical region. The symptoms begin with acute rhino-pharyngitis and they may be latent, subacute, or frankly acute. In this last form the puffiness suggests acute inflammation and suppuration seems likely; but resolution is the rule, and an abscess occurs only very exceptionally. The characteristic features of the disease are that it is always preceded or accompanied by slight catarrh of the upper respiratory tract, and that the subsequent swelling of the lower cervical region comes on abruptly and is afterwards definitely painful. It is best treated by hot applications, though local and general disinfection should not be forgotten.

### *Medical Responsibility.*

A workman invited one of his friends, an orderly at a private hospital, to give him some injections of cacodylate, and these injections were made in the hospital clinic unknown to the doctor in charge. After the twelfth injection inflammation developed, which resulted in the workman being admitted to another hospital, and so he brought an action for 50,000 francs damages against the medical practitioner of the clinic, whom he tried to make responsible for the acts of the orderly. The tribunal dismissed this demand, considering that the workman had made a direct application to the unqualified man to take care of him, had not approached the doctor, had had the injections at his own risk, and, therefore, had no claim on the director of the clinic.

### *Payment of Interns in Paris Hospitals.*

The interns in Paris hospitals receive from the Ministry of Public Assistance during the first year of their service an annual salary of 488 francs. This is raised gradually until, in the fourth year, they get 533 francs. They are also entitled at midday to food, whose value is estimated by the Ministry at Fr.2 90. These sums are inadequate nowadays. Five or six years of medical study are required before a man can become an intern, and he remains in that position for another four years. These doctors demand that their salary shall rise from 9000 francs a year for the first year to 10,200 francs for the fourth. They also ask to be lodged and to be paid during their month's holiday as is done in provincial hospitals. It is clear that a sum of 1000 to 1200 francs a month is the least that they can live on in Paris.

### *Salaries of Teaching Staffs.*

Recent decrees have altered the payment of the teaching staff of the faculties. At Paris the professors of the third class receive 29,000 francs annually; those of the second class get 32,000, and those of the first get 35,000. The agrégés engaged in teaching receive 21,000 francs; if they give no instruction they have only 13,500. The chefs de travaux receive, according to their class, from 18,000 to 21,000 francs and the préparateurs from 14,000 to 17,000 francs. In provincial faculties the scale of payment is rather lower.

---

## VIENNA.

(FROM OUR OWN CORRESPONDENT.)

### *Cause of the Deaths following Toxin-Antitoxin Administration.*

SOME 18 months ago there was a most unfortunate occurrence in one of our children's institutes. Six children died soon after receiving prophylactic injection against diphtheria, the chief symptoms being those of heart failure, and although the incident was at first kept secret the facts soon leaked out and a good deal of public feeling was aroused. Official explanations followed which culminated in the assertion that by an unknown and hitherto novel process a disintegration of the liquid must have taken place which destroyed the antitoxin and left only the toxic substance in action. The entire supply of the toxin-antitoxin mixture which had been manufactured at this time was withdrawn from the market; this was an easy matter because there is only one institute making this product in Austria. Naturally the confidence of the public, not to speak of the medical profession, was seriously shaken, and many people refused to have anything more to do with this kind of prophylactic injection although it is used extensively in other countries. There were those, however, who remained dissatisfied with the official version, and after prolonged investigation Prof. R. Grassberger, head of the public health department and professor of hygiene in the University of Vienna, now states that the cause of the accident was that in filling the ampoules the antitoxin was forgotten. According to this view the method was not in any way to blame, and it was simply negligence that was responsible for the disaster. Prof. Grassberger's open and bold statement has caused immense excitement, especially in the official quarters responsible for the institute which prepared the serum, and when he announced his intention of reporting on the affair and of producing his proofs in a paper to be read before the Medical Society such pressure was brought to bear on the society that the professor resigned his membership and withdrew his paper. Public attention, however, has now been thoroughly roused and both sides will have to produce their evidence; undoubtedly the matter will be cleared up before the courts in a short time.

### *Vacancies in the Medical Faculty of Vienna.*

A serious situation in the University of Vienna has been caused by the unexpected death of several professors within a short time of one another. A few weeks ago Prof. Friedrich Dimmer, the well-known ophthalmic surgeon, died at the age of 70 years, and his eye clinic, of which he had been the director for many years, will perhaps be dissolved. Such at any rate was the intention of the Ministry of Finance which has to find the funds for the institution, and naturally it has caused widespread consternation in medical circles. It has been justly pointed out in numerous articles and resolutions that the ever-increasing importance of ophthalmology, and of Vienna ophthalmology especially—we may recall the names of Fuchs, Fäges, and Arlt—did not allow of a purely bureaucratic measure of this kind, which would drive away many students and doctors from this country, and thus result in the loss of more money than could be saved in abolishing the expenses of the clinic. It is to be hoped that the idea will be definitely abandoned. The University staff has suffered another serious loss by the sudden death of Prof. Josef Kyrle at the age of 46 years. He had already done important work in dermatology, his principal investigations being concerned with the treatment of syphilis by malaria, the histology of skin diseases, and the eunuchoid conditions. He was destined to succeed Prof. Gustav Riehl, who is now finishing his honorary year and has passed his seventieth year, when he has to retire according to the rules of the University. Kyrle was a brilliant teacher whose clarity and impressive diction were reminiscent of the famous teachers of 40 years ago when Vienna was the Mecca of medicine.

### *Luetic Infection from a Corpse.*

At a recent meeting of practitioners a case was demonstrated of a rare infection with lues, when a student had injured his finger at a post-mortem on a prostitute who had been dead for about four hours. An ulcus durum appeared in due course at the site of the lesion and a salvarsan course is being given to the student. A similar case was reported by Prof. Lang in Vienna in 1900, and his patient was demonstrated some time ago by Dr. J. Löwy in Prague suffering from luetic hemiparesis, whilst Prof. A. Ghon has also reported the occurrence of luetic infection from a corpse only two hours after death. These cases prove the vitality of the *Spirochæta pallida* and should be a warning to pathologists.

---

Manchester Dental Hospital.—The forty-second annual report, whilst recording an increase of nearly 2000 in the number of patients treated during the year, states that only £504 has been subscribed in answer to an appeal for £10,000, and that the deficit is now over £2000.

---

## BUCHAREST.

(From our own Correspondent.)

### *Public Instruction in the Laws of Health.*

At a meeting of the Medical Society held recently Prof. Manicatide recommended the teaching of hygiene in the lower classes of secondary schools. As he pointed out, nearly every medical officer of health year by year deplores the immense wastage of infant life, and, though some of this wastage is the result of neglect and indifference, very much more is due to ignorance. Hundreds of lives are lost every year because the public does not know the simple laws of health, and a large number of infants' lives are sacrificed because people cling to old superstitions about measles and whooping-cough. These are still thought of as mild diseases of no account, in spite of oft-repeated warnings that they kill more than all the other so-called dangerous infectious diseases put together. In some parts of Roumania it is commonly supposed that if a child with whooping-cough be set near an open fire so that he inhales the smoke he will get rid of the disease after one or two sittings. Efforts have been made to enlighten the public by scattering broadcast leaflets dealing with infant feeding and the like, and popular lectures are given. But the fact remains that amongst the poorer classes most mothers are unteachable, and it is now accepted that the best way to conduct the campaign for health is to give lectures and introduce the teaching of hygiene in the lower classes of secondary schools instead of leaving it till the children reach the top form, as has been done heretofore. By inculcating a few of the elementary facts about personal hygiene, domestic hygiene, and the feeding of infants into the next generation of school-children—and especially of girls—the public health would undoubtedly gain enormously.

### *Mental Derangement after Typhoid.*

In a recent paper on this subject Dr. Munteanu referred to the great vagueness of the literature, the only comprehensive work attempted having been done by some Paris students a score of years ago, and later by an American, Dr. Edsall. The frequency of mental changes, the character of the psychosis, and the prognosis when they have developed are the points of special interest. The idea among clinicians that derangement is relatively rare is an erroneous one, about 100 cases being easily found in literature. It is commonly stated that the changes are maniacal, but many cases of dementia and melancholia have been recorded. A boy of 11 years in Dr. Munteanu's practice, who had severe typhoid and was subsisting on a low diet on account of hæmorrhages, developed delusions and symptoms of meningitis. He recovered from both. Another child developed a psychosis characterised by irrelevant fears, delusions of all the senses, and extreme irritability. His condition gradually improved. Clinicians say that the cases recover; psychiatrists say that they do not. The best policy is to feed the patient well whenever mental symptoms occur, as a prophylactic against dangerous psychosis, for there is certainly some relation between the period of starvation and the incidence of insanity in these cases.

### *Changing Mortality Statistics.*

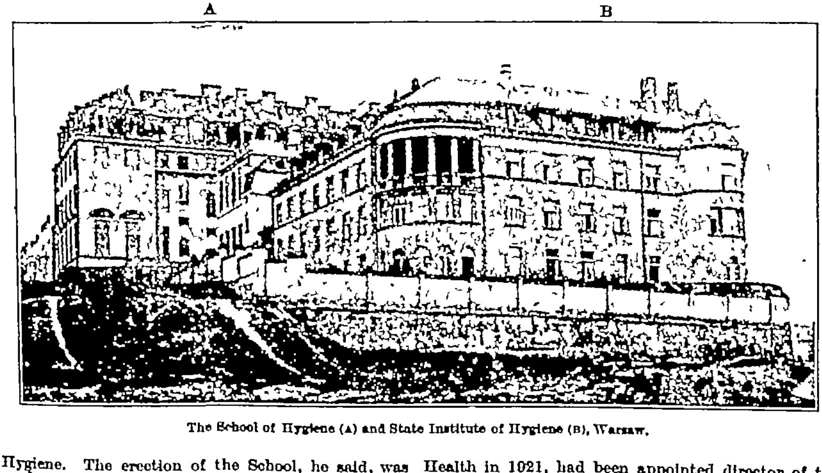
The Roumanian Statistical Bureau was established in 1923, and the first exact report on general mortality was published last month. It is demonstrated that the increase in pneumonia deaths from 1922 to 1925 was 2 per cent.; of heart disease, 5 per cent.; of apoplexy, 7 per cent.; and of cancer, 8 per cent. On the other hand, there has been a decrease of nearly 25 per cent. in deaths from consumption and of 15 per cent. in bronchitis. Better knowledge of infantile complaints and the growing use of the different antitoxins and serums have considerably reduced the mortality from the diseases of childhood in the last

20 years. From 1922 to 1925 there has been a decrease of deaths from cholera infantum of 16 per cent.; from diphtheria of 18 per cent.; and from convulsions 24 per cent. Some common ideas about the prevalence of diseases in certain areas are dispelled. Consumption caused, in 1925, deaths to the number of 118 per 100,000; in the same year the death-rate from this disease in Poland, a much colder country, was 138 deaths per 100,000.

## PUBLIC HEALTH SERVICE IN POLAND:

### NEW SCHOOL OF HYGIENE.

(FROM A CORRESPONDENT.)



The School of Hygiene (A) and State Institute of Hygiene (B), Warsaw.

THE new School of Hygiene was opened in Warsaw on Tuesday, April 20th, with appropriate ceremonial. The Prime Minister of Poland, Count SKRZYNSKI, opened the proceedings in French to an audience which included representatives of many European countries, of the United States of America, and Japan. He was followed by Dr. WROCZYNSKI, General Director of the Public Health Services of the Republic, who, speaking on behalf of the Minister of the Interior, welcomed the assembly who had been invited to participate in the inauguration of the new section of the Institute of Hygiene—namely, the School of Hygiene. The erection of the School, he said, was rendered possible by a generous subvention from the Rockefeller Foundation, and while he felt much gratitude for this most effective help, which had enabled his Government to open the new School, he expressed special appreciation of the moral support thus evidenced. In response to the subvention the Polish Government would provide for the maintenance of the School, which was erected on land belonging to the State; but he indicated that while the School is open it is not yet finished, equipment and such essentials as a library having yet to be found, in spite of additional and considerable expenditure incurred by the Government.

"The Rockefeller Foundation," he continued, "have done more for us. The housing difficulties make it imperative for us to provide dormitories for the students of the School. We were anxious, too, to set up a field station giving opportunity for practical work for the teaching staff and students, an office for the district medical officer of health, and a series of preventive medicine institutes. The Foundation, being prevented by its programme from giving financial assistance for the establishing of dormitories, was good enough to obtain for us coöperation with the Joint Distribution Committee, of New York, who will acquire jointly the necessary property for the Government.

"The creation of the School of Public Health," he said, "dates back to 1920, the first period of political existence of independent Poland, when epidemics were still raging on eastern territories and great effort was necessary to control the spread of infectious diseases consequent upon the war and the movements of refugees. We have learnt during that period that the efficiency of an epidemiological campaign and the effectiveness of all sanitary measures depend, in the first place, upon the standard of training of public health services, of their scientific equipment, and ability to perform the important task of safeguarding the safety and health of the people. The Institute of Hygiene, under its first name, that of the Central State Epidemiological Institute, was created in 1919, on the initiative of Dr. Ludwik Rajchman, its present director, and also the director of the Health Section of the Secretariat of the League of Nations, Dr. Tomasz Janiszewski, at the time Minister of Public Health, giving full support to the project."

Dr. Wroczynski then detailed the aims of the Institute and School, showing them to be designed to cover all the usual activities for the production of serums and vaccines, for biochemical work, for the investigation of epidemiological problems, and for providing machinery for the technical researches which form the basis for State and scientific measures. He showed that a school of public health was the logical development of the Institute, the object being to train fully qualified officers for administrative service, and added that Dr. Witold Chodzko, Minister of Public Health in 1921, had been appointed director of the School. An agreement had been concluded, he said, for full coöperation between the Rockefeller Foundation and the Government, the Foundation providing scholarships which enabled the present teaching staff to acquire the American methods of sanitation, raising the technical standard of the sanitary personnel. A legislative measure now enjoined that candidates for first-grade public health posts had to undertake a special course of hygiene lasting one year and including practice as well as technique. He pointed to the rapid development of public health service in Poland since the war, and insisted that the training of the public health officer could not stop at theory, for such an officer required practical knowledge of administration, of the organisation of sanitary institutes, and of the general importance of public health as it presented itself to the statesman and the legislator. He continued:—

"Our School of Hygiene, which proposes not only to train medical officers for the public health of the State, but also men destined to work in the State administration or the boroughs, has evolved a programme in which special attention is being given to the practical development of their work. A series of model sanitary districts, which keep in direct contact with the School as well as other institutions, has already been organised—one of an urban type and the other of a rural. This School forms, with the Institute and the public health service of the State, a complete unit, in a position to teach in the light of immediate requirements and in close contact with the problems which present themselves in collective life. The welfare, the physical and moral standards of the population, the efficiency of labour, and the progress of the country depend upon the competence of the administration. At the very moment when the reorganisation of the public administration must be effected on strictly economical lines, it is necessary to increase the efficiency of the individual to as high a level as possible. The realisation of the ideals can only be reached with a perfectly well-trained personnel, if a small one."

The ceremony received a special significance in view of the presence of representatives of foreign Governments, of members of the Public Health Training Commission, and of members of the Health Committee of the League of Nations. It closed with a formal welcome in the name of the Polish Government to the eminent guests and to the representatives of the Rockefeller Foundation.

### *New Buildings.*

The picture of the School and Institute shows the buildings in juxtaposition. The new School, over which the assembly was conducted, is a large building excellently adapted for the various purposes which it is intended to serve, and a good beginning has been made in the equipment, whose deficiencies were noted by Dr. Wroczynski. The building is on five floors with a basement. The top floor is reserved for the residential accommodation of the staff; the third floor is devoted to the chemical laboratory and chemical class-rooms; the second contains the grand amphitheatre and various lecture-rooms; the first floor is devoted to a museum of hygiene, in which exhibits relating to industrial hygiene and occupational physiology are included. On the ground floor are placed the students' bacteriological laboratory and class-rooms, and in the basement, in addition to the various electrical and other installations, there are a dining-room for the staff and the additional amenities.

Visits were also paid to two model sanitary districts, one urban and one rural, and the general opinion of the representatives of other countries present at the function was one of high approval of the energy and comprehensiveness displayed in the construction of the buildings and in the ideals of work.

## MEDICINE AND THE LAW.

### *Time-limits in Actions of Negligence against Hospital Doctors.*

THE legal point left outstanding in the case of Venn *v.* Todesco and Elder has been decided in Mrs. Venn's favour. At two previous trials the jury disagreed over the charges of negligence in diagnosis which she brought against the two doctors who are the defendants. The way is now open for her to proceed to yet a third trial if she is not deterred by the strong personal opinions expressed by Mr. Justice McCardie [1] as to the inadequacy of the grounds of those charges. The defence was a denial of negligence and a reliance upon the Public Authorities Protection Act of 1893. The points of law now decided were twofold. First the plaintiff contended that Dr. Todesco and Dr. Elder could not rely upon the Act at the second trial last February because they had voluntarily abandoned that line of defence at the first trial last June. The judge was against the plaintiff here. He said the February proceedings were a trial de novo and the defendants were not precluded from pleading the Act. The second point was more complicated. Mrs. Venn's husband was in the Croydon Borough Hospital at the period when the alleged negligence of the two defendants occurred. Dr. Todesco was resident medical superintendent of the hospital, and Dr. Elder was assistant resident medical officer. Mr. Venn left the hospital and passed out of their care on April 26th, 1922. If the Public Authorities Protection Act, 1893, applied, then Drs. Todesco and Elder could not be sued unless the writ was issued within six months of that date—i.e., before Oct. 26th, 1922. The action was, in fact, begun (by the issue of a writ) on Dec. 6th of that year—after the time-limit had elapsed. But there is another Act, Lord Campbell's Act of 1846, which gives widows certain rights of action on the death of their husbands provided that they sue within 12 months of the death. Mr. Justice McCardie, in the face of a network of legal decisions which only the House of Lords would have power to overrule, has felt obliged to decide that Lord Campbell's Act applies to the exclusion of the Public Authorities Protection Act, and therefore Mrs. Venn's action, begun within 12 months of her husband's death, was not time-barred.

The learned judge hardly disguises his view that, as a general principle of statutory interpretation, there is no reason why the two Acts should not be construed together, in which case the defendants would have been able to protect themselves by means of the narrower time-limit of six months under the Act of 1893. And on general considerations he points out that his ruling may be unfair to persons in the position of Drs. Todesco and Elder. If the 1893 Act does not operate where death has occurred, if the time-limit in such cases is fixed only by Lord Campbell's Act, what follows? A man may be injured by alleged negligence and may not die till many years afterwards. His widow will then have a further 12 months in which to issue her writ. Thus the unfortunate defendant will be seriously prejudiced by the passage of years in meeting the case and dispelling the allegations made against him. This prejudice, due to lapse of time, is the very evil which the Act of 1893 was designed to prevent. It is to be hoped that the House of Lords may have an early opportunity of reversing the decisions by which Mr. Justice McCardie as a judge of the High Court was bound, and of assuring to the medical officers of hospitals the protection which Parliament presumably intended them to enjoy.

### *The Harnett Case: Dr. Fisher Wins.*

In Harnett *v.* Fisher the defendant doctor has succeeded upon the legal point, though the jury had found—as stated in this column last week—that the plaintiff had been sane in November, 1912 (when Dr. Fisher certified him), and that Dr. Fisher had not used reasonable care in certifying him. Dr. Fisher was able to plead the Statute of Limitations, an Act of James I., which bars out claims of this kind unless they are brought within six months of the date when the cause of action arose. Section 7 of the Act is a proviso that, where a plaintiff has been an infant or *non compos mentis* at the time when the alleged breach of duty towards him occurred, the period shall not begin to run until he comes of age or becomes sane. This would have helped Mr. Harnett if he had been *non compos mentis* when Dr. Fisher examined him in 1912, but the jury has decided that he was sane at that date, and by this finding in his favour they have deprived him of his extension of time for suing. It had been argued for the plaintiff that a man who has been shut up in a lunatic asylum must have the rights of a lunatic under the proviso to Section 7 of the Statute of Limitations. This the judge could not accept, as the plaintiff could not be simultaneously sane for one purpose and insane for another. Mr. Justice Horridge was impressed by the hardship to Mr. Harnett. Others will not forget that a doctor who is sued in 1926 for an incident which occurred in 1912 is at a grave disadvantage in defending himself. Dr. Fisher's case was conducted for him throughout by the London and Counties Medical Protection Society.

### *A Flaw in the Children Act.*

The Children Act of 1908 gave new powers of removing children from the custody and control of undesirable parents, but these powers do not go far enough. A serious omission is disclosed by a recent prosecution at the Hertfordshire Quarter Sessions, where a father pleaded guilty to three counts charging him with indecently assaulting his own daughter, aged 14 After he had been sentenced (to nine months imprisonment with hard labour), the court made an order—presumably under Section 21 of the Act—giving the custody of the child to her uncle and aunt until she reaches the age of 16 But there is another younger daughter, aged 8, in respect of whom there was no charge against the father, but of whom the father hardly seems a suitable person to have custody, the mother having died some years ago As the law stands, when the father is released at the end of his sentence he will be legally entitled to demand custody of this younger child Questions have been asked in Parliament of the Home Secretary, who replies that steps have been taken for the protection of the younger daughter, but that there is admittedly a defect in the Act The position is partially dealt with in paragraph 99 of the report of the Departmental Committee on Sexual Offences against Young Persons (Cmd 2561) The Committee there recommends that incest should be inserted among the offences enumerated in the first schedule of the Children Act; this would allow magistrates to take all the means provided by the Act for the protection of the girl victim if under 16 and to make maintenance orders In the interests of the girl's sisters the report goes on to recommend that machinery should be devised (in cases like that which was recently heard before the Hertfordshire sessions) to refer the circumstances of the girl and her sisters to a petty sessional court so that action may be taken for the guardianship of them all, due regard being had to the rights of the mother Not much has yet been done to give legislative effect to the Committee's recommendations.

---

[1] THE LANCET, March 13th, p. 560.

### *Abnormal Conduct and the Inference of Insanity*

In the proceedings just mentioned counsel for the defence asked the Bench to consider the medical aspects of the case, and expressed the hope that the day was not far distant when a man like the accused would be put in a hospital ward instead of a prison cell This was said by way of plea in mitigation of sentence; insanity was not raised as a defence The Bench does not seem to have paid special attention to the plea, but, just before Easter, there was a somewhat unusual case in which the Court of Criminal Appeal went out of its way to infer insanity from the abnormality of the accused person's behaviour At a criminal trial at the Cornish assizes it appeared that a man had induced a firm of solicitors to draw up a will under which his nephew left him his money. He then forged his nephew's signature and formed, as it seems, a plan to bring the will into operation He borrowed his nephew's gun and he lay in wait in his nephew's garden, watching for his nephew to come out of the house. Unaware of their danger, the nephew's wife and maidservant came out and were shot at one being injured slightly, the other seriously Eventually the accused was apprehended and put upon his trial. He was sentenced to 14 years' penal servitude at the assizes, but the Court of Criminal Appeal reduced the sentence to one year's imprisonment The appeal was not very fully reported, but it appears to have been thought that the facts indicated insanity and that the court below had not given sufficient attention to this aspect of the man's conduct. It is believed that counsel for the defence at the assizes did, in his address to the jury, dwell upon the indications of insanity, but counsel's speeches are the only part of the trial which is not officially reported on the shorthand notes; consequently, they do not appear on the dossier of documents which is presented to the Court of Appeal. That court presumably felt that it had not the power or the justification to change the verdict into one of acquittal on the ground of insanity. In the absence of further information it seems a strange result, for, if a man is insane enough to make it proper to cut his sentence down from 14 years to one year, then even the one year's imprisonment seems a year too many, and one would expect to see him treated as a criminal lunatic. And if the judges found this strong inference of insanity in the mere recital of the prisoner's strange behaviour, and if they partly acted upon the inference unassisted by mental experts' evidence, is this not one of those cases which suggest that a trained alienist would be exceedingly useful if called in to act as examiner and assessor to the Court of Criminal Appeal?

The Home Secretary has withdrawn from Dr. Samuel Grahame Connor, of 21, Dryden Chambers, Oxford street, London, the authorisations granted by the Regulations made under the Dangerous Drugs Act, 1920, to duly qualified medical practitioners to be in possession of and supply raw opium and the drugs to which Part III of the Act applies.

# The Services.

## ROYAL NAVAL MEDICAL SERVICE.

Surg Rear-Admiral E. Sutton succeeds Surg Rear-Admiral C. M. Beadnell at the Royal Naval Hospital at Chatham; and Surg. Rear-Admiral D W Hewitt succeeds Surg Rear Admiral A. Maclean at the Royal Naval Hospital, Haslar

## ROYAL ARMY MEDICAL CORPS

W D Dyson and J R. Stokes to be temp Lts.

### TERRITORIAL ARMY

Capt J E. Rusby (R.A.M C. Res. of Off ) to be Capt.
Capt. W J Hirst resigns his commn. and retains his rank.
Capt. H B Dodwell (late R.A.M C., Spec. Res.) to be Capt
Lt A. Swindale (late R.C of Signals, T.A.) to be Lt.
Lt. W T de Vere Thomson (late R.G.A., T.F ) to be Lt

## ROYAL AIR FORCE.

No 602 City of Glasgow (Bombing) Squadron: J C.H Allan to be Flight Lt.

## INDIAN MEDICAL SERVICE.

Majs. Khandu Ganpatrao Gharpurey, D C. V FitzGerald, B Higham, S. T Crump, and J MacG Skinner to be Lt.-Cols.

Capts. Kotyvenkata Rama Rao, Hari Chand, Nehchal Das Puri, Monindranath Das, Jagannath Balkrishna Vaidya, J M. R Hennessy, C. H N Baker, M L. Treston, Amir Chand, R. Lee, and C de C Martin to be Majs.

The King has approved the retirement of Lt.-Col. W. J Collinson and Maj R. B Nicholson.

Colonel F H. G Hutchinson, A D M S. of the United Provinces District, will succeed Major-General T H. Symons as Surgeon General with the Madras Government. Lieut Colonel R. Row, O B E., has been appointed Professor of Morbid Anatomy and Curator of the Museum Grant Medical College Major J D Sands, professor of medicine Medical College, and first physician College Hospital, officiates as Principal of the College. Major A. W Truter has handed over charge of Central Jail, Montgomery, to Captain N D Puri Dr O C. Vardon officiates as Director of the Pasteur Institute, vice Lieut -Colonel Hodgson. Dr M. Stowe has been appointed to the Agra Women's Medical School, vice Dr N E. Trouton transferred. Dr R J L. Sladen, district surgeon G I P Railway, has been appointed Chief Medical Officer, Eastern Bengal Railway, vice Dr T. H Bishop, granted leave Dr K W. Blinkworth has been appointed Civil Surgeon, Garo Hills, Assam. Major W O Walker, civil surgeon, Serampore, has been appointed Civil Surgeon of Hooghly Dr J F C. Rose Meyer has been appointed Resident Medical Officer, European Civil Hospital at Allahabad, vice Dr H. P Burns transferred. The following have been granted leave: Lieut Colonel F A. F Barnardo, principal, Medical College, Calcutta; Captain G Shanks, professor of pathology, Medical College, Calcutta; Lieut.-Colonel E. C Hodgson, director, Pasteur Institute; Lieut.-Colonel W Lapsley, civil surgeon, Agra; Major A. E Mathews, civil surgeon, Hardoi; Dr T H Bishop, chief medical officer, Eastern Bengal Railway; Dr H. G H Munrowd, civil surgeon, Garo Hills; Lieut.-Colonel C A. Godson, civil surgeon, Hooghly.

## DEATHS IN THE SERVICES.

Fleet Surgeon Hugh Winckworth Macnamara, R.N , retd , who died on April 10th at Peppard, near Reading, at the age of 69, qualified with the M.R.C.S. Eng in 1880 and obtained the L.R.C.P Lond two years later In the following year he joined the Royal Navy and served as surgeon in various ships, including the *Surprise* in the Mediterranean, when the Duke of Edinburgh was Commander-in-Chief. In 1890 he was appointed to the *Excellent* gunnery school at Portsmouth, and later to the dockyard at Gibraltar, when in 1895 he was promoted to staff surgeon. In the meantime he had taken the D.P.H., *being one of the first*, possibly the first, naval medical officer to do so. He then joined the *Cordelia* in the West Indies, and in 1899–1901 was on the staff of the Chatham Hospital. In 1901 he was appointed P.M.O. to the *Ophir*, which conveyed the Prince and Princess of Wales, now the King and Queen, to India, and later served in China, being promoted Fleet-Surgeon in 1903. Other posts which he held were those of senior medical officer of the training ship *Impregnable* and of the *Royal Arthur* and *Euryalus*, flagships of Admiral Sir Day Hort Bosanquet in the West Indies, while he was also in medical charge of the R.M.L.I. at Portsmouth, and subsequently was afloat in the *King Alfred*, of the Home Fleet, at Devonport. In September, 1912, he joined the *Lion*, flagship of Rear-Admiral David Beatty, and retired in 1913.

Col. *Charles Arthur Johnston*, C.B., D.S.O., I.M.S. (*retd.*), who died in a nursing home in London on April 23rd in his sixtieth year from encephalitis lethargica, was the son of the late J. W. Johnston, of Rajahmundry, India, and was educated at Edinburgh University, where he graduated in medicine and surgery in 1888. He entered the Indian Medical Service in 1890. He served in Manipur in 1891 (medal with clasp), in the Burma campaign, 1891–92 (mentioned in dispatches and clasp), the Tirah Campaign, 1897–98 (medal with clasp), and in China in 1900 (medal). During the war he served in East Africa in various capacities and was several times mentioned in dispatches, and awarded the C.B., Military Division, and D.S.O. in 1917. He was severely injured during the campaign by being blown up on the railway. He was promoted to Major in 1902, to Lieut.-Colonel in 1910, and to Colonel in 1920. Colonel Johnson was a keen medical officer and rendered valuable service in connexion with the treatment of malaria. He was a popular officer throughout the Indian Army and married, in 1912, Isabel, elder daughter of the late Dr. J. H. Honeyman, of Auckland, New Zealand, and of Lady Bruce-Porter. He leaves a widow and one son.

The death on April 5th of Major George Pritchard Taylor, R.A.M.C., who was mauled by a tiger near Mhow while out duck shooting, is reported from Bombay. Major Taylor was appointed lieutenant in 1909 and captain in 1912.

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 17TH, 1926.

*Notifications.*—The following cases of infectious disease were notified during the week: Small-pox, 213 (last week 190); scarlet fever, 1388; diphtheria, 893; enteric fever, 36; pneumonia, 1876; puerperal fever, 46; cerebro-spinal fever, 6; acute poliomyelitis, 2; encephalitis lethargica, 64; dysentery, 13; ophthalmia neonatorum, 112. There were no cases of cholera, plague, or typhus fever notified during the week.

Of the 213 cases of small-pox 103 were notified from the county of Durham, scattered over 20 or more boroughs and urban districts, while cases were reported from all except two of the nine rural districts, the areas most affected being Chester-le-Street, Easington, Houghton-le-Spring, and (especially) Lanchester. From the county of Derby 46 cases were reported, all except three from Derby C.B. itself. A second case has been reported from the county of Lincoln, Gainsborough being the new centre; the remaining cases as before from the counties of Northumberland, Nottingham, and Yorks, West Riding.

*Deaths.*—In the aggregate of great towns, including London, there was 1 (0) death from enteric fever, 99 (43) from measles, 9 (3) from scarlet fever, 59 (4) from whooping-cough, 41 (13) from diphtheria, 66 (11) from diarrhœa and enteritis under 2 years of age, and 302 (59) from influenza. The figures in parentheses are those for London itself. The notified deaths from influenza for the 105 great towns are only eight in excess of those of the previous week, London itself showing a substantial diminution from 74 to 59. The number of measles deaths has just failed to reach 100.

INFLUENZA IN SCOTLAND.—In the Registrar-General's weekly return for the week ending April 17th the deaths from influenza in the principal towns of Scotland numbered 84, being 31 fewer than in the previous week. In Glasgow the recorded deaths from influenza numbered 45 (including cases where influenza was a contributing cause of death), and from all respiratory diseases (not tuberculous) 184.

---

Dr. J. Hall-Edwards, of Birmingham, who has lost one hand and several fingers of the other as a result of dermatitis due to work with X rays, has been elected an honorary life member of the British Medical Association.

## MINERS' NYSTAGMUS: A TENTATIVE THEORY.

*To the Editor of* THE LANCET.

SIR,—The suggestion of Dr. J. Prosser Davies as to the origin of miners' nystagmus contained in your issue of April 24th is certainly ingenious, all the more so that interference with the vestibular nerve may produce nystagmus. At the same time whole areas and, indeed, whole countries are free of the disease. Are we to infer that in these areas and countries the engine-drivers are all very cautious and careful men and that in the districts where the disease abounds they are all somewhat reckless?

To my mind the disease is due to a poison of some kind. Dr. Robson suggests that it is due to carbon monoxide inhalation. There is something to be said for that view, but, personally, I regard it as due to some toxin. In its paroxysmal characters it shows some similarity to ague and in other features it reminds me of encephalitis lethargica.

I am, Sir, yours faithfully,

Glasgow, April 24th, 1926. FREELAND FERGUS.

## X RAYS IN CANCER.

*To the Editor of* THE LANCET.

SIR,—Most surgeons in this country will be surprised to read Dr. Reginald Morton's letter (THE LANCET, April 17th) in regard to their views and prejudices and to learn that they have taken no very serious notice of what has been going on at the Erlangen clinic for some years past. And they will, I think, be interested to learn that a "fair and honest" trial of the Erlangen technique in place of operating would alter the lot of the patients suffering from cancer for the better, "mentally, physically, and materially." There are many surgeons far better fitted to reply to these criticisms than myself. But it so happens that on March 30th I had the honour of delivering the ninth Silvanus Thompson lecture before the Röntgen Society, and I took for discussion my experience of the treatment of growths of the urinary organs with the hard X rays. And it further happens that I have had the privilege of Dr. Morton's assistance in treating a number of cases of malignant disease of the urinary organs with the Erlangen technique.

The use of the hard rays in cancer has been for some time under careful trial in this country. If all the cases that are seen in the early stage have not been turned over to the radiologist the reason is that good results are obtained by operation in early cases, whereas the result of treatment by the hard X rays in such cases has not come up to the extravagant claims made for it in some quarters. In my experience the results of operation for, say, carcinoma of the bladder, are good in regard to immediate and remote results and are steadily improving as early diagnosis becomes more common. Dr. Morton's statement that surgery in malignant disease is at a "dead end" is, so far as my experience is concerned, quite inaccurate. Further, Dr. Morton claims for radiology that it is without the risks of operation. This is simply not true. There are many serious risks connected with the use of the hard rays, and of these Dr. Morton must be perfectly aware.

Dr. Morton claims for himself "a high degree of success in the relatively few early cases of malignant disease that have been referred to me before there had been any surgical interference." This brings me to a second point. I submitted ten cases of malignant growth to Dr. Morton for treatment by the hard X rays. None of these cases had been operated upon; eight were early cases in good and even robust health, and with a small or moderate-sized circumscribed local growth. Two were advanced cases. Nine of these patients are dead (one from cause apart from the cancer) [illegible] and one is alive without any recurrence. The final result of these cases must surely have been overlooked by Dr. [illegible] in making the claims embodied in his letter.

I do not wish to give the impression that I am antagonistic to the use of X rays in cancer. The reverse is the fact, and my [illegible] Thompson lecture is evidence of this. But I feel most strongly that Dr. [illegible]'s statements in regard to surgical results are misleading, and that his claim as to the results of the Erlangen technique is extravagant.

I am, Sir, yours faithfully,
John Thomson-Walker.

[illegible], W., April [illegible], 1926.

## EARLY PROGNOSIS IN CANCER AND TUBERCULOUS DISEASE.

*To the Editor of* THE LANCET.

Sir,—In these diseases the general practitioner has to answer the natural anxiety of the patient and of the immediate relations and friends; this anxiety takes the form of inquiry as to the chances of a permanent cure. Long experience teaches that what is told in "utmost confidence" to a relation or friend sooner or later leaks round the entire family, and so it becomes a matter of self protection to maintain continuity of opinion when trying to give real help to people in distress.

The general intelligence of the public in the matter of disease is far in advance of, say, 20 years ago. In putting a question requiring an opinion they are not to be put off with an answer devoid of "yea" or "nay," nor with a quotation from long-worded reports of the bacteriologist, pathologist, or radiologist; it will not unload the responsibility for an opinion from the practitioner in attendance.

We "G.P.'s" are not in the happy position of the medical or surgical specialist hidden away in the impersonality of a consulting-room; we are on the ground every day to minister to the latest mental or physical requirement. I suggest the following as a good working basis for prognosis; I am leaving out the obviously hopeless cases, applying it only to those who look well and who the uninformed think only "out of sorts."

The subject first gains knowledge of anything wrong by a hæmorrhage from the lung or vagina, or the discovery of a small tumour in the breast or neck, or possibly abdomen. He or she is reported "out of sorts and avoids people." The two early symptoms forming an unfavourable prognosis are: (1) a continuously increased pulse-rate; (2) an altered mentality, taking usually the form of secretiveness.

1. *Increased Pulse-rate.*—Here I exclude Graves's disease and primary endocardial trouble, but I do not exclude anæmia, often the first symptom of tuberculous disease in the lungs, or pleura, or of a "silent" malignant growth. This increased pulse-rate is of ill omen if it is out of proportion to the temperature of a problematical pulmonary tuberculous infection. When I say it is "problematical" that the lung has become *involved*, it is because many early cases lack the usual physical signs, the stethoscope failing to find a small deposit *in the centre of a lobe of the lung*; happily the hyperæsthesia of an intercostal nerve is an unfailing signpost, and explains the increased pulse-rate.

*Illustrative Cases.*—A woman, aged 31, consulted me about a tumour. It was the size of a large walnut, situated in the upper and inner quadrant of the left breast; there was no other *evidence of disease*; pulse-rate 80–90, temp. subnormal, and *continued so* morning and evening *for* seven days before operation. I excised the breast and subcutaneous tissues and muscles from the axilla to below the costal margin, and the pathological report was duct carcinoma. *In answer to the usual question from the friends I gave a bad prognosis.* The increased pulse-rate continued until my patient died *within 12 months of cancer in the region of the stomach.* This is typical of many cases that [illegible].

[illegible]

A woman had a cancer of the breast removed [illegible] months [illegible].

The pulse-rate of [illegible] from 80 to 90, [illegible].

2. The Mentality of the patient [illegible]; it is equally helpful with the pulse-rate in suggesting a good or bad prognosis. Dealing [illegible], my observations over a period of 25 years lead me to distinctly believe that in tuberculous and [illegible] disease, where there is a distinctly altered mentality, however slight, a bad outlook [illegible]. The friends of the patient will describe this condition in various ways—"not the same," "funny in her ways of late," "odd," "not so open as she used to be." The sum total of all this can be covered by the word secretiveness. When an ordinary individual gradually alters the usual mode of dealing with friends and becomes "peculiar" in small matters—just very reticent or reserved, but not spiteful or malicious, and displaying no hallucinations—then search for a blood infection cause.

3. The individual with altered mental condition avoids a consultation with a doctor even when the latter is an old friend.

*Illustrative Cases.*—A deep ulcer in the breast of an old lady was discharging foul-smelling pus, but her husband and maid knew nothing about it until she sent for me, so that I could sign her death certificate. The employer of an elderly butler asked me to see him as the butler had "[illegible] smell." I found a large fungating growth of the anus, but as in the former case, no one in the house had any knowledge of the condition or had heard any complaint. In a case of slight melancholia the patient had "pain in the back," when aspiration in the region of the right sacro-iliac joint found pus teeming with [illegible]. Once I was called to see a delicate looking woman who had cut her throat. She had a tuberculous deposit at the left apex, which was unknown and untreated, and she died a few weeks after the attempt at suicide from general tuberculous infection.

Early cases are missed over and over again because the modern practitioner is not taught that clinical observation is the first line of knowledge, the help of the various specialists being the second, and "team work" is not available in scattered country districts. The practitioner having no "team" at his command, his usefulness and success depend upon his skill as a clinician, and the good clinician notices small symptoms. With him the chronic cough leads to an examination of the middle ear; the *type of pain* in the sole of the foot calls for an examination of the sacral plexus via the rectum; a persistent pain over the occiput calls for a digital examination for a tender area in the maxilla, and later an X ray to prove the clinical belief that there is a buried end of a tooth.

4. I quote such cases to show that the clinician can and must be *self-dependent*; such dependency is strengthened and encouraged by reading the inspiring article in THE LANCET of last week by Mr. Hastings Gilford on "A Method of Cancer Research." The true clinician must try and know all that is to be known. *Again and again he has to ask for proof of his findings from the bacteriological and biochemical laboratories; he is a partner in research work.*

A persistent increased pulse-rate and a slightly *altered mentality I have found* important signposts in early tuberculous and cancerous infections. Marcus Aurelius said: "*He who does (I says) nothing makes no blunders.*" He evidently had forgotten the medical practitioner.

I am, Sir, yours faithfully,
W. H. [illegible], M.D.
Consulting Surgeon, [illegible] Hospital.

Dorchester, April 26th, 1926.

# Obituary.

## JOHN ALFRED KNOWLES RENSHAW, M.D. CAMB.

THE death of Dr. Knowles Renshaw, which occurred at his home at Sale on April 25th, came unexpectedly, although for some time he had suffered from heart trouble. Dr. Renshaw belonged to a family of doctors which has made its home in the Altrincham and Sale district. At one time there were 12 Renshaws whose names appeared in the Medical Directory, and they all belonged to this family and lived within four miles of the house where Dr. Knowles Renshaw lived. With his grandfather, Jeremiah Renshaw, who qualified in 1833, and his father, Charles Jeremiah Renshaw, he kept up the succession for nearly 100 years. He received his medical education at Cambridge, Manchester, the London Hospital, and Vienna, and qualified in 1895. After graduating in medicine at Cambridge in 1896 he became house surgeon at the Manchester Royal Infirmary and later went into general practice in his own district of Sale. Gradually, however, he devoted himself more and more to aural and laryngeal work, and in the end he specialised exclusively in it. His chief public work was on the staff of the Manchester Consumption Hospital and of the Crossley Sanatorium. Always friendly and helpful, and certainly without any enemies, Dr. Renshaw leaves a gap which will be hard to fill, and Manchester is the poorer for the loss of his genial presence. The greeting received a few days before his death from Cambridge medical men assembled at their annual dinner gave him special pleasure. He leaves a wife and children.

## FREDERICK STEPHEN PALMER, M.D. DURH., F.R.C.P. LOND.

THE death of Dr. F. S. Palmer on April 21st removes a physician of ability whose career was unusual in the profession.

The son of a practitioner at East Sheen, Surrey, Frederick Palmer received his medical education at Westminster Hospital and became M.R.C.S. and L.S.A. as long ago as 1869. After holding the post of house surgeon at Westminster Hospital, he was for four years resident medical officer at the Radcliffe Infirmary, Oxford; having thus equipped himself for his life's work, he settled down at East Sheen like his father before him. Here he carried on for many years a very successful general practice. Amongst his patients were the ex-Royal Family of France, and he was on friendly terms with the late Comte de Paris. In 1885 he graduated as M.D. at the University of Durham, and in 1901, 32 years after qualification, he left his practice in Surrey, settled in London, and successfully sat for the examination for Membership of the Royal College of Physicians. As clinical assistant at the Hospital for Sick Children, Great Ormond-street, and at the National Hospital, Queen-square, he acquired further experience, and such were his energy and determination that he was able to establish himself as a consulting physician and neurologist. In 1904 he was elected physician to the West End Hospital for Nervous Diseases, where he rendered excellent service for many years both in his clinic and as chairman of the committee of management. He was at the disposal of everyone whom he could help and his skill and sympathy ensured that these were many. During the war his energy and business acumen made him invaluable to the hospital, and it was not until 1921 that he joined the consulting staff, the age of retirement having been postponed for him. For many years Dr. Palmer was also physician to the Hostel of St. Luke and to the Royal Society of Musicians, and his experience found expression in numerous contributions to medical journals. He was president of the West London Medico-Chirurgical Society, and in 1911 his successful work as a consultant led to his election as F.R.C.P. Lond.

The bare record of Dr. Palmer's life is evidence of courage and ability. To his personal charm and character his friends bear witness. "Dr. Palmer was a fine specimen of the courteous Christian gentleman with high ideals," writes a colleague, "and he retained his mental and physical vigour to the end."

Dr. Palmer leaves a wife, and a daughter married to Surgeon-Captain Campbell, R.N. (retd.).

## HENRY WICKLIFFE FISHER, L.R.C.P. EDIN.

THE death of Dr. H. W. Fisher on April 20th removes a general practitioner of high reputation in the Sefton Park district of Liverpool. Dr. Fisher was 60 years of age. Educated at University College, Liverpool, he took the conjoint Scottish diplomas in 1889 and settled in Sefton Park some 20 years ago. Early in his medical career he had the misfortune to suffer from serious deafness, but in spite of this affliction he continued undaunted with his work, so that his practice, instead of dwindling because of his disability, continued to increase. Acumen, energy, and devotion combined to make him a very valuable adviser, and those with whom he came into consultation testify to his diagnostic skill. His energy for work was irrepressible. Dr. Fisher was a keen cricketer and took a great interest in the local club. He is survived by his widow and a family of three.

THE LATE DR. D. T. BELDING.—Dr. Davy Turner Belding, who died on April 15th at the age of 62, had been medical officer of health to the East Dereham U.D.C. for the past 30 years. He was a son of the late Mr. Davy Turner Belding, of South Creake Hall. Receiving his medical education at St. Bartholomew's Hospital, he acted as prosector at the Royal College of Surgeons from 1886 to 1887, and qualified as M.R.C.S., L.R.C.P. in the following year. Then he returned to East Dereham and entered into partnership with Dr. H. C. Hastings, whose pupil he had earlier been and to whose practice he ultimately succeeded. During the war Dr. Belding, who was a Territorial officer, acted as A.D.M.S. to the East Anglian division and later served under the Eastern Command, eventually taking rank as brevet lieut.-colonel. He was a keen golfer, being at one time captain of the Royal Norwich Golf Club, and a prominent Freemason. He leaves a widow and daughter.

THE LATE DR. MAXWELL ROSS.—Until the end of last year Dr. James Maxwell Ross, who died on April 10th, was medical officer of health for the county of Dumfries. He was born in Ross-shire 72 years ago and graduated in Arts at the University of Edinburgh in 1876, proceeding to a degree in medicine in 1881. Two years afterwards he became F.R.C.S. Edin. and he also took the degree of B.Sc. in public health. In Edinburgh he acquired considerable experience of aural work and thoroughly qualified himself for his post as a medical officer of health. He was responsible for the sanitary administration of a number of towns and villages besides the county of Dumfries and carried out his duties with tact and sympathy. Dr. Ross's ability and knowledge were recognised by his appointment as examiner in public health to the Royal College of Surgeons of Edinburgh and as a member of one of the consultative councils of the Scottish Board of Health. He was also at one time President of the Society of Medical Officers of Health of Scotland and a member of the Council of the British Medical Association. Dr. Ross's wife died some years ago and his elder son, Dr. Dermid Ross, died in 1920. There is one surviving son.

---

QUEEN CHARLOTTE'S MATERNITY HOSPITAL.—Sir Samuel Scott, presiding at the annual meeting of governors and subscribers of Queen Charlotte's Maternity Hospital on April 26th, said that there were only 700 beds for maternity patients in the voluntary hospitals of London. More beds were urgently needed at Queen Charlotte's Hospital, which constantly had to refuse applicants owing to lack of accommodation. Last year nearly 2000 patients were admitted to the wards, and the committee was considering the addition of an operating theatre. An interesting fact had recently come to light regarding the foundation of the hospital. Dr. G. C. Peachey had discovered an old manuscript in the British Museum from which it was clear that the hospital was founded in the year 1739 and was thus the oldest maternity hospital in the United Kingdom. The hospital was still in debt to the extent of £0000, and contributions were urgently needed.

## NOTES ON CURRENT TOPICS.

### THE MIDWIVES AND MATERNITY HOMES BILL.

THE Midwives and Maternity Homes Bill, a measure introduced by Lieut.-Colonel Fremantle and supported by the Government to amend the Midwives Acts, 1902 and 1918, and to provide for the registration of maternity homes and other purposes, was read a third time on April 27th. The Bill had been previously considered by Standing Committee A of the House of Commons, with Sir Richard Barnett in the chair, when important amendments were introduced.

#### *Elimination of the Handy Woman.*

Clause 1 provides that the following subsection shall be substituted for Section (2) of Section (1) of the Midwives Act, 1902 (relating to the certification of midwives):—

> "Any person not being certified under this Act who attends a woman in childbirth otherwise than under the direction and personal supervision of a duly qualified medical practitioner shall, unless that person satisfies the court that the attention was given in a case of sudden or urgent necessity, be liable on summary conviction to a fine not exceeding £10."

Sir Kingsley Wood (Parliamentary Secretary to the Ministry of Health) moved a drafting amendment to leave out the words "any person not being," and to substitute the words "if any person being either a male person or a woman not." The object, he said, was to make it perfectly clear that there should be no possibility of admitting any man to the Midwives Roll.

Dr. Vernon Davies asked how this would affect medical students who, as a part of their training, had to undertake a certain number of midwifery cases on their own and not under the supervision of a doctor from the hospital. In cases of necessity or difficulty such students could send to the hospital for skilled help.

Sir Kingsley Wood said he thought that such students would have to act as they had done hitherto, under the responsibility of the doctor who sent them.

Dr. Davies said they could not under this clause, because it said "Under the direction and personal supervision of a duly qualified medical practitioner." It might happen, if the case was a normal one, that a qualified doctor did not see the case from beginning to end.

Sir Kingsley Wood said they could discuss that when they came to the question of "personal supervision," but he wanted to make it clear so far as this part of the Bill was concerned, that they must not in any way, even by implication, suggest that there was anything like a male midwife. There had been certain cases, particularly in the county of Durham, in days gone by, where an undesirable practice had at any rate been in existence, and men had acted in these cases. They wanted to avoid that. He would give further consideration to the question of medical students if necessary.

Colonel Fremantle said he thought that the case was perfectly met under the Bill by the words "under the direction and personal supervision of a duly qualified medical practitioner," because in all the medical schools the attendance on women in childbirth was under the direction and supervision of a qualified medical officer of the hospital all through. As the clause was to be amended it would meet the case.

Major Hills had an amendment on the paper to substitute for "the personal supervision of a duly qualified medical practitioner," the words "in the presence of a duly qualified medical practitioner." As the Chairman ruled that this amendment would be cut out by the passing of Sir K. Wood's amendment he was allowed to discuss certain points in connexion with it along with the new subsection before the Committee.

Major Hills said that he objected to the words "personal supervision," as they were too vague, and it might be held that a doctor was in personal supervision of an uncertified woman if he had employed that woman and given her a general direction as to the conduct of the case. It is felt by the Central Midwives Board that these words were too uncertain, and, while it was admitted that in cases of emergency it might be necessary for an uncertified woman to act, it should not be the general practice that she should do so, except in the presence of a duly qualified doctor. He agreed that that proposal raised certain difficulties, one of which was that nobody could say exactly when a birth was going to take place, and it would, of course, make the clause much more stringent. Nevertheless, they wanted to prevent the practice of midwifery by unqualified women, and he was rather afraid that if the clause was left as it was in the Bill that they would admit the unqualified woman midwife. It might be the case that the clause in the Bill would be fulfilled if the doctor telephoned or talked to the uncertified woman.

Colonel Fremantle said that on behalf of the Central Midwives Board he had an amendment on the paper which was very similar to that of Major Hills. He thought that the Midwives Act worked extremely well, but even in his profession there were a few black sheep. There were undoubtedly cases where diehards of the medical profession, who had been used to working with certain handy women, continued to do so within the letter of the law. The question they had to deal with was the exceptions. He had put down a proposal that the handy woman should be allowed to practise only in the case of the personal attendance of the doctor, and that is an amendment which was suggested by the Central Midwives Board and other bodies who worked with them. When they were considering the actual working of this proposal he was asked at what stage in the confinement should the doctor be required. If they said during labour, that lasted sometimes 24 hours, sometimes 36 hours, and even 48 hours, and the doctor, in justice to his other patients, could not be expected to be present the whole time. On the other hand, if they said "actual delivery," then the doctor had to wait and wait. Of course, he had other pressing cases, and while he was away, and before he could get back, often the child was born. One other objection to his proposed amendment was that it would penalise the handy woman for the fault of the doctor. The medical man was the person who should be made primarily responsible in these cases. He would be prepared to withdraw his amendment if he could see that definite steps would be taken to induce the General Medical Council to regard the conduct of a medical man, in deliberately abstaining from being present in the case of childbirth, as infamous conduct. If the General Medical Council would tune up doctors to carry out the letter and spirit of this clause that was all that was required.

Mr. Rhys Davies said he was in favour of the amendment, but he failed to understand the meaning of what was stated about men doing midwifery, who were not qualified men. He wished to know how many there were of these unqualified men, and whether it was intended to rule out these men who were acting in confinements and who were not medical men. If so, were there sufficient women to do the work? He would not like to do anything to reduce the number of those who were doing this kind of work, whether they were men or women.

Sir Kingsley Wood said there had been a practice in certain parts of the country, which the Central Midwives Board had expressed themselves very strongly against, of men acting in cases of this kind without any experience or training such as that received by medical students and without any doctor behind them at all. At the back of a medical student there was always some medical man who must take the responsibility, but in the case of these unqualified men that was not the case. One of the reasons why the Government were supporting this Bill was that it was making for the time when unqualified persons, male or female, would be prevented from acting as midwives. But they could not achieve that object all at once, because they had not sufficient women at present to do the work. He thought the proposed new clause was a great step forward. The Act of 1902 simply laid down that—

> "From and after April 1st, 1910, no woman shall habitually and for gain attend a woman in childbirth otherwise than under the direction of a qualified medical practitioner."

The words "habitually and for gain," in practice had proved not particularly helpful, and people had been able to avoid the restrictive character of the clause by proving that it was an isolated case and that they were not habitually engaged. The words in the old Act which states simply, "under the direction of a qualified medical practitioner," were really very vague, and it might well be, as had been proved in several cases, that a man by being present simply at the beginning of a case would have strictly complied with the section, and that was the end of his responsibility. The new clause took the matter very much further, and anything about habitually practising was left out and, in order that there should be no quarrel over that particular matter, the clause said, "Under the direction and personal supervision of a duly qualified medical practitioner." He believed those words threw a much greater obligation on the woman who was attending these cases than on the medical man himself. Obviously, if this phrase had to be interpreted in the courts, it really meant taking over the whole responsibility and conduct of the case. It did not simply mean a direction on the telephone, because that might very well have taken place under the Act as it was at present. Personal supervision meant that a medical man had actually to take charge and the woman had to act under him. If they said "In the presence of," it would practically mean that the whole proceedings under this clause would be a dead letter, It would mean that the doctor would have to be present throughout the whole of the confinement to be absolutely safe, not only during labour, which, unfortunately, sometimes occupied a good deal of time. It was perfectly true that the Central Midwives Board did at one time favour the words "and in the presence of," but it had been pointed out to them where those words would lead them, and he understood that the Central Midwives Board were now content with the clause as on the paper. The Ministry of Health took the same view. Anxious as everyone was to bring about a better state of affairs, one often ruined a reform by going too far. It had been suggested to him that it would be useful if he could see whether the General Medical Council would do something in those cases, which, so far as his knowledge of medical practitioners was concerned, were very rare, where a medical man covered an unqualified woman and allowed her to proceed; and that the mere fact that he did so might be held to comply with this section. He thought that it was far better, as in a case of other professions, if the medical profession could itself bring about the necessary reform in a small number of cases. They might perhaps be able to take action in the case of a medical man who so far forgot his professional duty as to allow a woman to proceed in this way. He would undertake on behalf of the Ministry of Health to consult the General Medical Council to see whether something could be done in that direction.

After further discussion Sir KINGSLEY WOOD's amendment was agreed to, and Clause 1, as amended, was added to the Bill.

### *Fees to Suspended Midwives and Called-in Practitioners.*

Clause 2 of the Bill provides that:—

> (1) Where on an appeal to the Central Midwives Board by a midwife who has been suspended from practice by the local supervising authority it is shown to the satisfaction of the Board that the suspension was not due to any default on the part of the midwife, the Board shall (notwithstanding anything in Subsection (2) of Section 6 of the Midwives Act, 1918) direct the local supervising authority to pay to the midwife such sum by way of compensation as, having regard to the circumstances of the case, seems just to the Board, and the local supervising authority shall forthwith make a payment to the midwife in accordance with the direction.
>
> (2) Subsection (2) of Section 14 of the Midwives Act, 1918 (which imposes a condition on the payment of a fee to a medical practitioner called in to assist a midwife in case of emergency), shall have effect as though at the end thereof there were added the words "and shall submit his claim within two months from the date on which he was called in."
>
> (3) Subject to the sanction of the Minister of Health, a local supervising authority may make arrangements with any pregnant women in their area for the payment by such women to the authority, whether by instalments or not, of such sum as may be agreed to cover any liability which the authority may incur under Section 14 of the Midwives Act, 1918, in respect of fees payable to medical practitioners who may be called in by midwives in pursuance of that section, and Subsection (4) of that section shall not apply in the case of any woman who has entered into such an arrangement and has duly paid the agreed sum.

Sir KINGSLEY WOOD moved an amendment to leave out Subsection (1) and insert in its place the following:—

> (1) Where a midwife has been suspended from practice in order to prevent the spread of infection she shall, if she was not herself in default, be entitled to recover from the local supervising authority such amount by way of compensation for loss of practice as is reasonable in the circumstances of the case.
>
> In Subsection (2) of Section 6 of the Midwives Act, 1918, the words from "or where" to "infection" shall be repealed.

He said that in the great majority of cases the local supervising authorities had paid this compensation, but there had been a few cases where they had declined to do so. It was obviously unfair that a certain number of midwives should not get any compensation while their colleagues in other parts of the country did receive it. This clause made the matter obligatory and brought about uniformity in practice on this matter. The alteration in the Bill, as drafted, was to bring the Bill into conformity with the original Act, which did not admit of an appeal to the Central Midwives Board.

Dr. VERNON DAVIES said he thought the main idea of the Bill was to prevent the spread of infection. It was not always easy to decide whether a midwife was really at fault or not. It was sometimes extremely difficult to prove and it was worthy of consideration whether they should not leave out the words "that she was not herself in default," and say that all cases which were suspended should receive compensation. A midwife might attend a confinement and it might go wrong and there might be puerperal fever. Possibly—almost certainly—that woman was responsible, but they could not be quite certain. It was held by some authorities that women could get autogenous infection, and in that case they might be penalising the midwife. He said, therefore, that they should pay them all.

Sir KINGSLEY WOOD said he did not quite go so far as that. If the midwife was in default they could not ask a local authority to pay her the money, but if, on the other hand, it was purely due to a spread of infection, his clause secured for the first time that a local authority should be liable to pay such amount of compensation as was reasonable.

The amendment was agreed to, and Clause 2, as amended, was added to the Bill.

### *The Midwives Roll.*

Sir KINGSLEY WOOD moved to leave out Clause 3, which deals with the fee for the retention of names on the roll of midwives.

He said that the clause, as it stood, sought to impose upon the midwives an annual fee of 2*s.* 6*d.* and its real object was to keep the Midwives Roll up to date. There had been a great deal of difficulty about the roll. It had to be published annually and it contained at present some 70,000 names, but there were really only about 14,000 persons actively pursuing their profession. The names of the people who were really engaged in this work were supplied from year to year by the local authorities under whom they were acting, and they were the people who were really doing the work and whose names ought from time to time, at any rate, to be published. One could understand the desire of people who were administering this Act to have the roll kept up to date, and to eliminate, if possible, from it people who had dropped out, and at the same time to avoid expense, but this particular clause on the paper had been rather strongly objected to by a number of midwives who were not perhaps in very flourishing circumstances, and who were not very anxious to pay this half-a-crown every year. Secondly, there was an objection from the administrative point of view, and that was that it would mean a communication to each of these 70,000 persons every year in order to collect the money. Therefore, under the circumstances, they thought that the best way of dealing with the situation would be to have a new clause which the Committee would discuss at a later stage.

The clause was negatived.

Sir KINGSLEY WOOD moved to leave out Clause 4 of the Bill, which, he said, was no longer necessary. The clause was negatived.

### *Maternity Homes: the Administering Authority.*

Clause 5 of the Bill deals with the registration of maternity homes, and provides as follows:—

> (1) Any person who on or after the appointed day carries on a maternity home within the meaning of this Act shall, unless that person is registered in respect of that home, be guilty of an offence against this part of this Act, and shall be liable on conviction to a fine not exceeding £50 or, in the case of a second or subsequent offence, to imprisonment not exceeding three months either in lieu of or in addition to any such fine.
>
> (2) Application for registration shall be made to the local supervising authority in writing in the form prescribed by the Minister of Health, and shall be accompanied by a fee of 5*s.* All fees received by a local supervising authority under this section shall be paid into the county fund or the borough fund as the case may be.
>
> (3) Subject as hereinafter provided, the local supervising authority on the receipt of an application for registration shall register the applicant in respect of the maternity home named in the application:
>
> Provided that the authority may refuse to register the applicant if they are satisfied (*a*) that the applicant or any person employed by the applicant at the home is not a fit person, whether by reason of age or otherwise, to carry on or to be employed at a maternity home; or (*b*) that for reasons connected with situation, construction, accommodation, staffing or equipment, the home or any premises used in connexion therewith are not fit to be used for a maternity home, or that the home or the premises are used or to be used for purposes which are in any way improper or undesirable in the case of a maternity home.

Sir D. NEWTON moved an amendment to secure that the councils of non-county boroughs and urban districts should be established as the authority to administer the Midwives and Maternity Homes Bill in their areas. The whole question of the administration and regulation of midwifery and child welfare and the question of registration of maternity homes and matters of that kind was now dealt with under three statutes. There was the Midwives Act of 1902, the Midwives Act of 1918, and the Maternity and Child Welfare Act of 1918. This Bill would, of course, strengthen those Acts which were already on the statute book. The Midwives Acts of 1902 and 1918 were administered by the county council, and originally under the Midwives Act of 1902 the county council was authorised and empowered to delegate its powers to other local authorities within its area, but under the Act of 1918 those powers of delegation were withdrawn in respect of authorities to whom those powers had not then been delegated. As matters now stood there was no power of delegation on the part of the county council or the county borough in regard to these powers under the Midwives Acts of 1902 and 1918, and in regard to maternity and child welfare. Under the provisions of the 1918 Act, the Ministry of Health was definitely charged with the duty of determining which authority should administer the Act. The Ministry of Health had been given discretionary power to decide whether the Act should be administered through the county council or through a non-county borough council, or an urban district council. He understood that already through the exercise of these powers the Ministry of Health had authorised no less than 261 borough councils and non-county boroughs and rural and urban district authorities to carry out the provisions of the Maternity and Child Welfare Act. That was to say, within the area of 43 county councils the Ministry of Health had authorised 261 other councils to administer the Maternity and Child Welfare Act. He thought that indicated clearly that the view of many county councils was that the question of maternity and child welfare could best be administered by non-county boroughs and urban and rural district councils. It might be that there was a fear of overlapping, because even now there was a certain amount of it in regard to midwifery and the administration of child welfare and maternity laws. In urging that these powers under this Bill should be given to non-county boroughs in cases where they already administered the Maternity and Child Welfare Act he would like to point out that this question was one which was interlocked with the general question of health administration. These authorities were well qualified and well fitted to carry out the duties which would arise under this Bill. The registration of these homes was not really just a formal matter, but a matter which needed to be very carefully carried out. The registering authority had to see that the applicant was a fit and proper person to carry on a home, and here again he suggested that the local authority, fully conversant with all the local conditions, was the most sympathetic and the most suitable body to hear the applicant and to consider her side of the case. It was clear that the enforcement of by-laws dealing with the question could really be dealt with best by the local authorities on the spot, rather than by the major body, the county council.

Sir KINGSLEY WOOD, in opposing the amendment, said that the local supervising authorities under the Midwives Acts were the county councils and the county borough councils. For the first time they were proposing that there should be registration of maternity homes—a reform which Members of all parties had long desired and which he hoped we should be able to secure as a result of this Bill. Part 2 of the Bill said that the registration should be made by the local supervising authority, and under the terms of the measure, as at present drafted, the supervising authorities had very important duties to perform. They had to see that the applicant, or any person employed by the applicant at the home was a fit person, and they had to inspect and see that the situation, construction, accommodation, staffing—he particularly emphasised the word staffing—and equipment of the home was right and proper, so that people who went there should receive proper treatment. Obviously while he did not wish for a moment to minimise the work which had been done by the minor authorities of the country in regard to maternity and child welfare work, the people who must administer the registration of these homes, and carry out the supervision of them, were the very people who were acting under Part 1 and supervised the midwives of the country. They had already got under the county councils and the county borough councils the necessary machinery for the purpose. The Minister of Health attached the greatest importance to this amendment being defeated. He regarded this as a critical clause in the Bill, and the Government could not say how far they would be able to support the measure if this clause was carried. In 1918 the legislature actually took away from the authorities the power to delegate which was given them in 1902. This was done because the power of delegation had not been generally exercised, and in a few cases in which it had taken place it acted detrimentally to the administration of the Act and introduced elements of confusion and uncertainty. In conclusion, he was authorised to say to the Committee that the Central Midwives Board, who ought to know all about this work and who had long been anxious for this reform and who had had more experience than any people in this country of this work, and who were an impartial-minded Board, were very anxious that the provisions in this Bill as it appeared before the Committee should be maintained and that this further element of other local authorities should not be introduced because they believed that it would not only be more wasteful, but that it would introduce elements of confusion and uncertainty into the administration. For all these reasons he thought the Committee would be well advised to negative the amendment.

Mr. TREVELYAN THOMSON said the amendment had been put down on behalf of the Municipal Corporations Association and the District Councils' Association, and they were disappointed at the attitude of the Parliamentary Secretary to the Ministry of Health. There was bound to be a certain amount of overlapping whatever procedure was followed. There were 261 local authorities which had maternity and child welfare committees. What was their position if they had maternity hospitals? They would then have two authorities controlling maternity hospitals in one area. That would produce not only inefficiency, but extra cost. Surely the Maternity and Child Welfare Act had shown that the local authorities had efficiently administered its provisions, and as maternity homes were so closely connected with infant welfare, surely the two matters should be under one authority.

Mr. ARTHUR GREENWOOD said that he thought those who supported the amendment were under a misapprehension. Clause 5 really ought to be read in connexion with Clause 10 because the latter clause laid down perfectly clearly that the expression "maternity homes" in the Bill did not include hospitals or other premises maintained by local authorities. These proposals rather applied to those areas and local authorities which up to the present had not been sufficiently progressive to have their own maternity homes. He could not find it in his heart to have very much sympathy with them, and he was not at all sure that they should not be superseded by some larger authority. He suggested that the difficulty might be met by including authorities over a certain size. He should like to know (1) whether local authorities which now controlled maternity homes would not really be affected; and (2) whether they could extend their maternity homes provision and remain outside the scope of the Bill? If that were so he thought they had reduced the problem to very small dimensions.

Captain MACMILLAN said if the Government would give a guarantee that they would resist any amendments to Clause 10, when that stage was reached, which would tend to take away the rights of the local authorities for whom he was speaking—the larger boroughs without county borough powers—then, although he was in favour of the general principle of the amendment, he would be prepared to accept the Bill as it stood.

Major HILLS said that he had always favoured the larger authority and had intended to vote against the amendment, but he had been struck with the speeches of Captain MACMILLAN and Mr. GREENWOOD, who had pointed out that Clause 10, as drawn, would give a reasonable compromise between those who supported the county council and those who supported the non-county borough. As he read that clause it did allow progressive non-county boroughs to start their own maternity homes, and, if they did so, those homes would be under the non-county borough councils and not under the county councils. If it would ease the situation, he would be prepared not to move his amendment to Clause 10, which provided for the approval of the county council of the staff and equipment of a hospital in a non-county borough. Of course, the bigger question must be threshed out at some future time in connexion with the Poor-law, or some question of that sort, when they must come to some general allocation of the powers of different local authorities. As far, however, as this Bill was concerned, he thought that Clause 10 did what was required, and all that was necessary was that the Parliamentary Secretary to the Ministry of Health should assure them that their interpretation of Clause 10 was correct.

Mr. BASIL PETO said that the smaller local authorities had admittedly carried out the duties entrusted to them in 1918 satisfactorily and efficiently, and if Parliament now put over them an over-riding authority in respect of one particular matter they would tend to kill that ambition for public service by local authorities. He unhesitatingly supported the amendment.

Colonel FREMANTLE said they wanted to get at the mischief where it started, that was the bad midwife—there were not many of them now—or the thoughtless, perhaps kind-hearted, midwife, who took into her spare room a single girl in order to see her through her trouble. Eventually she might get two or three such women into her home, and that was the sort of maternity home where all sorts of things went wrong, and there was shocking loss of life. He would give two instances which were brought to him from the south and north of England. Here was one from the south, a case illustrating the importance of registration and inspection of maternity homes:—

> "A practising midwife lives in a small house, three bedrooms upstairs, two sitting-rooms and kitchen downstairs. She took in three maternity cases and in addition to these there were three adults and two children in the house. One child had a septic condition of the face. Here there existed overcrowding and a septic focus—result two cases of puerperal infection. The registration and inspection of maternity homes must apply to cases of this kind."

Who was the person who knew that home? It was the inspector of midwives, who was keeping under review every midwife on the roll. Let him give the other instance from the north of England. A midwife in that area was taking women into her house to be confined, and on one occasion she had as many as three persons at the same time. Following on the line of this midwife another one had now commenced the same practice and had already had several confinements in her house. From having had experience for 12 years of administering the Midwives Act, he knew the women who were working as midwives. It was the midwives who were starting this practice, and they were the women they wanted to get at. He was certain that everyone who had had experience of administration would say that the authority to administer the Midwives Act must be the authority who could get at these bad maternity homes when they were first started. That was the real danger. He quite saw the point which had been raised on behalf of the boroughs. He thought that Major HILLS had put in a very statesman-like way the difficulty of reconciling the rival authorities. He hoped they might have a compromise on this matter, because the Bill was a compromise. Before long they must get a rearrangement of the respective powers exercised by the county authority and the non-county authority in other measures which would come before the House. He appealed to the Committee on behalf of all those people who knew the wicked maternal mortality which was going on, and which it was the object of the Bill to prevent.

Mr. RHYS DAVIES said that he was rather inclined to the view that if they were to get information about these malpractices such information would travel to the officers of the local authorities before it would travel to the county council offices. Consequently he was almost inclined to vote for the amendment.

Sir KINGSLEY WOOD said it was not so much a question that maternity and child welfare work was analogous to the registration and inspection of these homes. He would be the last to interfere with the excellent work which was now going on in that direction, but the real analogy was the registration and supervision of midwives. Every midwife in the country had not only to be registered by the county council or county borough council, but had continually to be under supervision, and it seemed to him a great waste of time and money that when they had the power already in the hands of the larger authorities they should now turn round and say that the minor authorities should be responsible, although they had not the facilities for doing maternity and child welfare work as efficiently as the larger authorities, inasmuch as they had not the officers who could go round and inspect the homes. There were 312 maternity and child welfare authorities who were neither county nor county borough councils. Of that number only 20 had provided their own maternity homes. As regarded voluntary maternity homes used by maternity and child welfare authorities, he found that only 52 of the 312 authorities made use of maternity homes situated in their districts. These facts by no means minimised the importance of the work of maternity and child welfare, but they had a most material bearing when they came to decide which authority should carry on the work. The clauses of the Bill represented a very fair compromise. In Clause 10 it was provided that the expression "maternity home" should not include "any hospital or other premises maintained or controlled by a Government department or local authority . . ." By that means they amply safeguarded not only the homes at present established by these other authorities, but any future homes that might be established. He hoped the Committee would support the Bill as it stood.

The amendment was rejected by 25 votes to 8, and Clause 5, as amended, was then agreed to.

### *Cancellation of Registration.*

Clause 6 (cancellation of registration) was agreed to.

On Clause 7 (which deals with notices of refusal or cancellation of registration) several amendments were taken.

Colonel FREMANTLE moved an amendment providing that not less than 14 days' notice should be given to the applicant or the person registered by the supervising authority of their intention to make an order under the clause.

The amendment was agreed to.

A further amendment was agreed to giving the applicant or person 14 days from the receipt of the notice to show cause why the order should not be made.

Colonel FREMANTLE moved an amendment providing that any person aggrieved by an order made under the clause might appeal against it to Quarter Sessions as well as a court of summary jurisdiction.

The amendment was agreed to.

### *Keeping of Records.*

Clause 8 deals with the power of the supervising authority to make by-laws.

Colonel FREMANTLE moved an amendment providing that by-laws could be made with respect to records to be kept of patients received into and children born in a maternity home, and of children so born who were removed from the home otherwise than to the custody or care of any parent, guardian, or relative. He said the object of the amendment was to get at the root of certain cases of baby-farming.

The amendment was agreed to.

### *Notification of Deaths.*

Colonel FREMANTLE moved an amendment providing that by-laws might be made as to the notification of any death in a maternity home and the cause thereof.

Major-General Sir R. LUCE asked if this was not a very difficult question, and ought they not to have some explanation in regard to the certificate of the cause of death? After all, there was only one legal certificate of the cause of death, and a different cause of death might be given here. It did not say who was to be responsible for certifying the cause of death.

Sir KINGSLEY WOOD said that his department had given consideration to this amendment, and they thought that on the whole it was a desirable thing to include. At the present moment only the actual death itself had to be recorded, but he did not think that there would be any difficulty, and it would be a help to those people who desired to see progress in public health to know exactly what the cause of death was. The great majority of these homes were under medical supervision, and he did not think it would cause any difficulty that the cause of death should appear in these records.

After further discussion,

Sir KINGSLEY WOOD suggested that the amendment should not be pressed that day and they would consider later whether it was necessary.

Sir R. LUCE said his point was that they should be quite sure that the exact cause of death was given.

Sir KINGSLEY WOOD: That can be provided for in the by-laws.

The amendment was agreed to.

A further amendment was passed, striking out a provision that by-laws might be made "generally with respect to the conduct of maternity homes and for carrying into effect this part of the Act."

The clause, as amended, was added to the Bill.

Clause 9 (offences by companies) was agreed to.

### *Interpretation.*

Clause 10 (interpretation) reads as follows:—

In this Act unless the context otherwise requires: The expressions "register" and "registration" mean register and registration under Part II. of this Act; the expression "appointed day" means the first day of January, 1927; the expression "maternity home" means any premises used or intended to be used for the reception of pregnant women or of women immediately after childbirth, but shall not include (*a*) any hospital or other premises maintained or controlled by a Government department or local authority, or by any other body of persons constituted by Parliament or incorporated by Royal Charter; or (*b*) any hospital or other premises for the conduct of which a duly qualified medical practitioner resident therein is responsible; or (*c*) any premises used for the training of persons as midwives, which are approved for that purpose by the Central Midwives Board; the expression "offence against this Part of this Act" includes an offence against any by-laws made under Part II. of this Act.

Sir KINGSLEY WOOD moved to leave out paragraph (*c*) and to insert instead the following:—

"(*c*) any hospital or institution not carried on for profit and not used mainly as a maternity home which may be exempted from the provisions of Part II. of this Act by the local supervising authority."

He said it had been represented to his department that there were, up and down the country, a large number of small cottage hospitals which had no resident doctor, but were staffed with local doctors, who continued to attend their own patients who might happen to be in the hospital. These small hospitals did not strictly come within the definitions which preceded this paragraph, and he thought they should be exempted if the local supervising authority were satisfied that they were conducted on the lines indicated. The amendment was intended to meet the wishes of the medical men in question, who were, no doubt, doing very useful work.

Dr. DAVIES asked if "not carried on for profit" meant that if a medical man sent patients to a cottage hospital he would not be allowed to charge fees.

Sir KINGSLEY WOOD: He will certainly be allowed to charge for his own patients. It only means the home itself.

The amendment was agreed to, and the clause, as amended, was agreed to.

### *New Clauses: The Midwives Roll.*

Sir KINGSLEY WOOD moved the following new clause:—

(1) The Central Midwives Board may, if they think fit, cause the roll of midwives to be divided into two parts, of which one shall contain the names of all those practising midwives whose names have been supplied to the Board by local supervising authorities in the month of January in each year, in accordance with the provisions of Section 8 of the Midwives Act, 1902, and

shall be published annually, and the other shall contain the names of all other persons who are entitled to be on the roll, and shall be published at such intervals, not exceeding five years, as the Minister of Health may approve.

(2) The Central Midwives Board may from time to time by registered letter addressed to any woman whose name is included in the roll of midwives at her address as appearing therein, inquire of her whether she has ceased practice or has changed her residence; and if within a period of six months from the sending of such a letter no answer is received thereto, the Board may erase the name of that person from the roll, and may cancel her certificate, but without prejudice to the power of the Board subsequently to restore the name to the roll and to re-issue the certificate if it appears proper so to do.

The clause was read a second time and added to the Bill.

### *Access to Premises.*

Colonel FREMANTLE moved the following new clause:—

(1) An officer duly authorised by the local supervising authority may, subject to such regulations as may be made by the authority, at all reasonable times enter and inspect any premises which are used, or which that officer has reasonable cause to believe to be used, for the purposes of a maternity home, and to inspect any records required to be kept in accordance with the provisions of this part of this Act.

(2) If any person refuses to allow any such officer to enter or inspect the premises, or obstructs any such officer in the execution of his duty under this section, he shall be guilty of an offence against this part of this Act, and shall be liable, on summary conviction, to a fine not exceeding £5, together with, in the case of a continuing offence, a fine not exceeding £2 in respect of each day on which the offence continues after the date of conviction.

The clause was read a second time and added to the Bill.

### *Wearing of Badges.*

Colonel FREMANTLE moved a new clause providing that the power of the Central Midwives Board to frame rules under the Midwives Act, 1902, should include a power to frame a rule as to the wearing of badges by certified midwives. If a midwife is removed from the roll she must surrender the badge as well as her certificate.

The clause was read a second time and added to the Bill.

The committee stage was concluded and the Bill was ordered to be reported to the House.

### THE ECONOMY BILL.

On Thursday, April 22nd, Sir KINGSLEY WOOD moved the third reading of the Economy (Miscellaneous Provisions) Bill. After discussion, in the course of which important amendments proposed by Dr. DRUMMOND SHIELS, Dr. HADEN GUEST, and others were rejected, the third reading of the Bill was carried by 328 votes to 138—Government majority 190.

### SMOKE ABATEMENT BILL.

In the House of Lords on Thursday, April 22nd, the Public Health (Smoke Abatement) Bill passed through Committee.

### THE BUDGET.

Mr. CHURCHILL (Chancellor of the Exchequer) introduced his second Budget in the House of Commons on Monday, April 26th. He announced that he proposed to transfer £7,000,000 to the Exchequer from the surplus of £19,000,000 which had accumulated in the Road Fund, and to take a proportion of the revenue of the Fund which is estimated this year to amount to £3,500,000. A duty of 5 per cent from Nov. 1st next is to be imposed on legal bets made with bookmakers; a duty of £10 on certificates to be taken out by bookmakers; and a duty of £10 on the registration of each set of premises used by a bookmaker for receiving bets on credit. Relief is to be given for bets laid off, and for bets which for any reason are void. The credit period to brewers for payment of excise duty is to be reduced from three to two months. The three years average for the assessment of income-tax under Schedule D is to be abolished in accordance with the recommendations of the Royal Commission on Income-tax, which sat a number of years ago. The new basis of assessment is to be the income of the preceding year. This provision will come into operation in 1927. A duty on imports of wrapping paper at the rate of 16⅔ per cent. *ad valorem* is to be imposed from May 1st. A preference rebate of one-third of the duty will be allowed on Empire goods. The excise duty on home-grown chicory is repealed. It is proposed that the key industries duty of 33⅓ per cent. *ad valorem* is to continue for a further ten years, except that the rate on optical glass and instruments is to be 50 per cent. *ad valorem*, and the rate on arc lamp carbons 1s. per lb. The duties on hackney motor vehicles are to be made uniform in all districts, chiefly at the higher Metropolitan scale up to those seating 40 persons. There is to be a considerable increase on the heavier vehicles. Commercial goods vehicles of one to two tons and upwards, and tractors and road locomotives of from two to four tons and upwards are to pay higher duties. Vehicles in the last category used for agricultural haulage are not affected. Owing to the difficulties of substituting a motor spirit tax for the present motor licence duties, proposals cannot be made in the present Budget, but Mr. Churchill hopes to make the change in the lifetime of the present Parliament. Customs duties are extended to commercial motor vehicles. A new series of options are to be offered to holders of Savings Certificates of the first issue. It is not proposed to renew the Trade Facilities Act. Dumping is to be stopped by making the new duties on commodities apply from the day of introduction. The principle of a ten years' guarantee is to be extended to all the articles now enjoying Imperial preference.

## HOUSE OF COMMONS

### THURSDAY, APRIL 22ND.

### *Qualifications of Vivisection Inspectors.*

Mr. FENBY asked the Home Secretary if the inspectors under the Cruelty to Animals Act, 1876, were qualified veterinary surgeons and, if not, what special qualifications were required, if any, for the position.—Sir WILLIAM JOYNSON-HICKS replied: The answer to the first part of the question is in the negative. As to the second part, the majority of the Royal Commission on Vivisection in their report expressed the decided opinion that "it is essential that the inspectors should be qualified medical men of such position as to secure the confidence both of their own profession and of the public," and the qualifications which have been required in making these appointments are medical knowledge and standing, and such scientific attainments as would qualify their possessor to appreciate the nature and results of recent scientific research.

### *Sexual Offences against Young Persons.*

Mr. RADFORD asked the Home Secretary whether he was aware that in the recent case of a man who was sentenced to nine months' imprisonment for offences against his daughter aged 11 years, who had now been permanently removed from his control, the court was unable owing to the present state of the law to make a similar order with regard to a younger daughter aged 8 years; and would he consider the desirability of proposing the necessary amendments of the law to meet such cases.—Sir W. JOYNSON-HICKS replied: As I informed my hon. friend last Tuesday, adequate steps have been taken for the protection of the younger daughter. I am aware of the defect in the law to which attention was drawn by the Committee on Sexual Offences against Young Persons (see especially para. 99 of their report). I understand that the Committee on Young Offenders and Neglected Children is likely to propose a number of amendments to the Children Act, 1908, and I will consider the whole matter when their report is received.

### *Care and Education of Defective Children.*

Mr. BRIANT asked the President of the Board of Education the number of schemes for the care and education of defective children which have been submitted to the Board of Education up to March 31st, how many education authorities which were not provided in this respect had failed to submit schemes; and if any steps had been taken to impress them with the necessity of adequate provision for this class of children.—Lord E. PERCY replied: Since the issue of Circular 1340 I have received communications from 225 local authorities, of whom 160 have submitted proposals for making further provision for defective children or have stated that they have the question under consideration. Of the five authorities who made no provision for such children in 1925, three propose to make some provision this year. Authorities' programmes for 1927–30 under Circular 1358 are now being received and examined, but the examination has not yet proceeded far enough to enable me to give information as to their contents.

### *Amalgamation of Common Services.*

Mr. ROBERT HUDSON asked the Prime Minister whether he could inform the House if he was prepared to publish the report of the committee set up, under the chairmanship of Sir Alfred Mond, to consider and report on the amalgamation of services common to the Army, Navy, and Air Force.—Mr. BALDWIN replied: After careful consideration we have decided as a special case to issue the report of Lord Weir's Committee on the amalgamation of services common to the Navy, Army, and Air Force. This report and the reports of the Committee of Imperial Defence published in 1924 (Cmd. 2029), provide the basis of our existing system of coordination, and their conclusions have not been impugned on matters of principle by any subsequent inquiry. We do not think it necessary, or in the public interest, to publish any other report. The minutes of evidence of these inquiries, each of which occupied many months, are very voluminous, and it would not be in the public interest to publish them, but the detailed reports of a number of subcommittees will be published with the main report of Lord Weir's Committee.

### *Town-planning Schemes.*

Mr. TREVELYAN THOMSON asked the Minister of Health how many local authorities had put in hand town-planning schemes under the Housing and Town-planning Act of 1919, and how many local authorities had done nothing in the matter.—Mr. NEVILLE CHAMBERLAIN replied: 273 urban authorities and 51 rural district councils have prepared or are preparing town-planning schemes for the whole or parts of their districts or neighbouring districts. The number of boroughs and urban districts in which, so far as I am aware, no steps have been taken for the preparation of schemes is 825 and the number of rural districts 543. It must not be assumed, however, that all these districts include land for which town-planning schemes should be prepared.

## MONDAY, APRIL 26TH.

### *Chief Medical Officer for the Colonial Office.*

Captain CROOKSHANK asked the Secretary of State for the Colonies what were the functions of the recently appointed chief medical officer in his department; and whether this was a new permanent appointment or merely a re-allocation. of duties.—Mr. AMERY replied: The post to which my hon. and gallant friend no doubt refers is that of chief medical adviser, whose functions, as the title indicates, will be to advise me generally on all medical and sanitary matters arising in connexion with the Colonies and Protectorates, including measures to ensure continuity of policy and coördination of progressive action between different administrations. The post is a new appointment, the creation of which has been authorised in the first instance for a period of three years.

In reply to supplementary questions, Mr. AMERY said this was a whole-time appointment, and the salary was £1500 a year. The officer would be in close touch with the Medical Advisory Committee. The appointment was one which the Secretary of State made on his discretion after carefully considering the merits of the different candidates.

### *Salaries of Regional Medical Officers.*

Colonel WOODCOCK asked the Minister of Health how many regional medical officers were now employed and how many were similarly employed in 1918; what salaries they received and what were their duties; and whether they were entitled to pensions and at what rate.—Sir KINGSLEY WOOD replied: There were no regional medical officers employed in 1918. The present number of salaries of officers on this staff are: 4 divisional medical officers at £1600; 17 regional medical officers at £1400; and 16 regional medical officers at £1000, rising by £50 to £1400; 13 deputy regional medical officers at £800, rising by £30 to £1100. These salaries are all inclusive of bonus, and the posts are pensionable except for those officers who entered the service at 50 or over (21 in number). The duties are concerned chiefly with the Insurance Medical Service, and National Health Insurance Funds bear the appropriate share of their emoluments. The officers act as medical referees regarding the incapacity of insured persons for work and as consultants in giving second opinions in questions of diagnosis. In addition, they are required to carry out certain inspections under the Dangerous Drugs Act, 1920, and the Blind Persons Act, 1920, and, as needed, to inspect Poor-law institutions.

## TUESDAY, APRIL 27TH.

### *Day and Night Telephone Call Offices in Villages.*

Rear-Admiral BEAMISH asked the Postmaster-General if his department was in process of providing public telephone call offices available for day and night service in the villages; whether any such call offices had been established and, if so, where; and, if not, would he state what the prospects were for providing these modern necessities; and whether there were any difficulties.—Sir W. MITCHELL-THOMSON replied: Rural telephone call offices installed in local post-offices are normally available only during the hours when the post-office is open; but urgent calls can generally be made at other hours upon payment of a disturbance fee, if there is a responsible person on the premises. Such calls are rare, and to provide villages with kiosks available for night service would in most cases involve expense out of all proportion to the use made of the facilities. A kiosk can, however, often be provided if the annual deficit is guaranteed by persons interested. A list of villages where day and night telephone service is provided is not readily available.

### *The Spahlinger Treatment.*

Mr. BRIANT asked the Minister of Health if any steps were being taken to make further investigation, if this was necessary, into the results obtained in the cure of phthisis by the Spahlinger treatment; and, in view of the importance of the question to the health of the community, if Government assistance would be given in order to make it available to the large number of persons suffering from this disease.—Sir KINGSLEY WOOD replied: My right hon. friend has offered to send competent medical inspectors to study M. Spahlinger's work at Geneva, and to facilitate scientific investigation in this country if M. Spahlinger will supply his materials and method of use, but up to the present neither invitation has been accepted. The second part of the question does not, therefore, arise.

Dr. VERNON DAVIES asked if it was not the fact that M. Spahlinger has not got the necessary money.

Sir KINGSLEY WOOD replied that that might be so, but directly the Ministry received the necessary information and materials they would be glad to go into the matter.

Mr. T. JONES inquired if the Ministry of Health did not possess a certain amount of discretionary power to give financial assistance in such a case. Was the hon. gentleman not aware of the fact that a large number of trade-unions had already contributed substantially in order to try to make this work a success?

Sir KINGSLEY WOOD: No. I think the right course has been taken in this case—namely, to offer to send our officers to Geneva to study these cases or to ask, on the other hand, that this gentleman should send the material here when we shall be glad to investigate it.

Mr. CLYNES asked if these offers of investigations had been made quite recently.

Sir KINGSLEY WOOD replied in the affirmative. They had been made repeatedly during the last three years.

# Medical News.

UNIVERSITY OF CAMBRIDGE.—At recent examinations the following candidates were successful:—

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.

*Part I., Physics and Electrotechnics.*—Gilbert B. Bush, Arthur E. I. Connolly, Austin C. Dixon, William C. Douglass, William R. Dupré, Henry H. Elliot, Mollie Fisher, Margery Freeborough, Raymond B. Gorst, Alan R. Laurie, David P. Levack, Hendrik J. Louw, Peter J. McKenna, Charles W. McKenny, Elsie J. Mann, Robert R. Morrison, Frederick G. Nicholas, Rees Phillips, John O. Priestley, James Raffan, Francis L. Rayner, Ffrangcon Roberts, Solomon J. Rom, Frederic G. Rose, Albert C. Rusack, Satis Chandra Sen, James O. P. Smith, Henry T. Stack, John G. Stephens, Mary L. Stewart, Charles F. O. White, and Harry M. Worth.

*Part II., Radiology and Electrology.*—Gilbert B. Bush, William C. Douglass, William R. Dupré, Raymond B. Gorst, Pam Harumal Jhangiani, Alan R. Laurie, David P. Levack, Charles W. McKenny, Elsie J. Mann, Robert R. Morrison, Frederick G. Nicholas, John O. Priestley, James Raffan, Ffrangcon Roberts, Satis Chandra Sen, and Harry M. Worth.

SOCIETY OF APOTHECARIES OF LONDON.—At recent examinations the following candidates passed in the undermentioned subjects:—

*Surgery.*—N. H. C. Allen, Guy's Hosp.; G. H. Bickmore, Charing Cross Hosp.; S. B. Browning, Guy's Hosp.; S. E. Hymans De Tiel (Sect. I.), Royal Free Hosp.; C. H. St. Johnston, Birmingham; J. B. Lurie, St. Thomas's Hosp.; P. H. L. Moore, St. George's Hosp.; T. C. Pain, Guy's Hosp.; and E. H. Rampling, St. Thomas's Hosp.

*Medicine.*—C. B. Ball, Sheffield; C. F. L. Haszard, McGill; A. C. Hill, Liverpool; J. L. Hopkins, Guy's Hosp.; D. P. Mitra, Charing Cross Hosp.; M. N. Nicolson and M. Pettigrew, Sheffield; W. H. D. Priest, King's Coll. Hosp.; J. B. Scarr, Manchester; J. Shibko, Cardiff; A. D. Shubsachs, Manchester; and J. W. Whitney, London Hosp.

*Forensic Medicine.*—G. H. Bickmore, Charing Cross Hosp.; C. F. L. Haszard, McGill; W. O. R. Fischer, St. Thomas's Hosp.; J. L. Hopkins, Guy's Hosp.; D. P. Mitra, Charing Cross Hosp.; M. N. Nicolson, Sheffield; W. H. D. Priest, King's Coll. Hosp.; and J. B. Scarr and A. D. Shubsachs, Manchester.

*Midwifery.*—L. G. Apps, London Hosp.; K. Girgis, Manchester and Charing Cross Hosp.; J. E. Howard, St. Mary's Hosp.; and L. Schapera, London Hosp.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: G. H. Bickmore, A. C. Hill, J. L. Hopkins, C. H. St. Johnston, D. P. Mitra, W. D. H. Priest, E. H. Rampling, J. Shibko, and J. W. Whitney.

UNIVERSITY OF GLASGOW.—At the graduation ceremony held on April 24th the following awards were made:—

The Captain H. S. Ranken, V.C., Memorial Prize in Pathology to William A. Mackey; the Bellahouston Gold Medal for eminent merit in thesis for M.D. to Hugh S. D. Garven; the Straits Settlements Gold Medal for thesis for M.D. on a subject connected with Tropical Medicine or Tropical Hygiene to Walter Telfer; the Macleod Gold Medal in Surgery to Edward Collier; and the Asher Asher Gold Medal in Laryngology and Rhinology to William A. Mackey.

The following degrees have also been conferred:—

*M.D.*—With honours: John Glaister and Donald M'Intyre. Ordinary degree: Percy Bellwood Farrar.

*M.B., Ch.B.*—With honours William Scoble and Ronald Guthrie Lendrum. With commendation Anna M. Robertson, John Chalmers Olive C. H. C. MacRae, Abraham Mellick William A. Lochhead Agnes Moncrieff Stuart I. A. Laidlaw Archibald Hanton James Campbell and Marion W. Gray.

Ordinary degree William Allan, James Anderson May Anderson, William Anderson, Roderick D. G. Balfour David K. Ballingall Frank C. M. Bamford, Arthur F. Beaton, William Beattie Andrew Bernard, George G. Blair William S. Boyle James Brown, Joseph S. Brown, Katharine R. Brown, Winifred Buchanan, Hutchison Burt, Ada M. Cameron Rina B. Campbell, David P. Cuthbertson John Denholm, Mary E. Devine, Alexander S. Dick, Henry A. A. Doherty, James Durie, Thomas C. Findlay, William H. Fletcher, Findlay J. Ford, Robert S. France James A. Fraser, James Fryer, Charles S. Garrott, Norman C. Gellatly Elizabeth H. Gemmell, Robert G. Gemmell, Ernest W. Grahame, Robert C. Grieve, Mary A. Griffin, Walter Haddow, *Robert Hall, Leslie E. Hamilton, Margaret C. P. Hamilton,* William C. Harris, Constance E. M. Herbertson, Alexander D. Hutchison, John Innes, Philip G. E. Jolley, Robert S. Kerr; David Kilpatrick James L. Kydd, James S. Laurie David D. Lawson William H. Lindsay Miriam E. M'Allum Alastair M'Cracken, James N. M'Cully Donald Macdonald George Mackendrick, William M'Lelland, Andrew A. MacManus, Alexander M. M. Murray, William G. M'Naughton, Ian H. M'Neil Thomas G. H. Martin Victor C. Meyer Robert B. Miller, Thomas M. C. Montford, James Morrison William A. Murray, Mary M. E. Mycroft, Agnes S. Nutt, Thomas S. O'Neill, Dugald C. Orr, James S. Orr, David Prentice Malcolm S. Purvis, Florence Read, Catherine Ross, James Sharpe William Shirkey, Alan F. Shirras, Thomas Sim John Stewart, James H. Thomson, Archibald Walker, Janet B. C. Waugh William Whitelaw, Helen M. Wightman, William Wilkie, and Edward A. Wilson.

Royal College of Physicians of London.—Prof Hugh MacLean will deliver the Oliver-Sharpey lectures on Tuesday, May 4th and Thursday, May 6th at 5 P.M. at the College, Pall Mall East The subject will be Carbohydrate Metabolism in Health and Disease and any member of the medical profession will be admitted on presentation of a visiting card

National Hospital for Diseases of the Heart A two weeks special course in cardiology will begin on Monday, July 5th instead of Monday, July 12th, as previously arranged

Society of Medical Officers of Health.—A meeting of the School Medical Group will be held at 1, Upper Montague-street Russell-square London, W C on Saturday, May 1st at 3 P.M., when Dr Edgar H. Wilkins, now an assistant school medical officer at Birmingham and formerly Director of School Hygiene New Zealand Public Health Department will read a paper on School Medical Work in New Zealand The meeting will be open to all members of the society and to others interested in school medical work

International Physiological Congress.—The Twelfth Congress will be held in Stockholm from August 3rd to 6th. Intending members are asked to forward without delay their names and addresses, together with the amount of their subscription (20 Swedish crowns) to the secretary, Dr G Liljestrand Karolinska Institutet, Stockholm, Sweden from whom full information can be obtained. An excursion through the north of Sweden and Norway and other smaller trips will start immediately after the congress if a sufficient number of members give notice of their intention to take part

Fellowship of Medicine and Post Graduate Medical Association.—On Wednesday, May 5th at 2 P.M. Mr L. E. C. Norbury will give a special afternoon demonstration at St. Mark's Hospital for Diseases of the Rectum to which all members of the medical profession are invited On May 3rd the Royal Waterloo Hospital will begin a three weeks course in Diseases of Women and Children. There will also be an intensive course beginning on the same date at the Central London Throat Nose and Ear Hospital. This will last until May 22nd and is divided into clinical and operative parts which may be taken separately if desired The Maudsley Hospital will provide a series of lectures and demonstrations on psychological medicine throughout the month. The Royal Westminster Ophthalmic Hospital will hold a course in ophthalmology from May 3rd to 22nd Another course continuing throughout the month is one in venereal diseases held at the London Lock Hospital; this includes clinical demonstrations and formal lectures. Dr Eric Pritchard will hold an afternoon course at the Infants Hospital from May 9th to 22nd There will be an intensive course in medicine surgery and the specialties at the Royal Northern Hospital from May 31st to June 12th. Other courses will be given in June on diseases of children bacteriology diseases of the chest, gynæcology, urology There will also be a general practitioners course Copies of all syllabuses of the General Course programme, and of the *Post-Graduate Medical Journal* may be had on application to the Secretary of the Fellowship at 1, Wimpole-street London, W 1

Royal Institution.—Prof Joseph Barcroft will lecture on the Lungs on Tuesday, May 4th, at 5 15 P.M.

National Association for the Prevention of Tuberculosis.—The Prince of Wales will preside on Friday, July 16th, at a dinner in aid of the Association's funds.

Middlesex Hospital.—In 1925, the annual report records the number of out patients increased by more than 14 000 to nearly 100 000 There was a deficit on the year's working of £2347

Royal National Orthopædic Hospital.—The twenty first annual report lays stress upon the "urgent and vital need" of additional accommodation at the country branch at Stanmore, and £10 000 of the £87,000 required for extensions has still to be obtained.

At the quarterly meeting of the directors of the Naval Medical Compassionate Fund held on April 23rd, with Surgeon Vice-Admiral Sir Joseph Chambers Medical Director-General of the Navy, in the chair, the sum of £105 was distributed among the several applicants.

The League of Mercy.—The Prince of Wales will be present at a ball to be held at Claridge's Hotel London, on Tuesday, May 11th, in aid of the League of Mercy for the support of hospitals. Tickets may be obtained from the secretary at 20, Cockspur-street, London S.W 1

Messrs. Cassell and Co, Ltd, announce for early publication the third edition of "Diseases of the Nose and Throat" by Sir StClair Thomson. The work has been revised and considerably enlarged, and many new illustrations have been inserted.

Dangerous Drugs Acts.—Sir William Willcox will address the South West London Chemists Association at the Balham Constitutional Club, 221, Balham High road S.W, on Wednesday, May 5th, at 9 P.M. on the Dangerous Drugs Acts: their Application by the Physician and the Pharmacist. Medical men are invited.

Pure Milk for Edinburgh Hospitals.—The Edinburgh Public Health Committee and the Treasurer's Committee have jointly decided that the corporation shall maintain a herd of tubercle-free cows to supply Grade A (Tuberculin tested) milk to its various institutions. About 105 gallons will be required daily, but by reason of the difficulty of collecting a sufficient number of cows capable of giving milk that will pass the tuberculin test, some time must elapse before the arrangement can be carried out completely

Herbert Jones Testimonial Fund.—The following is a preliminary list of subscribers to this fund, which is being raised as a testimonial to the public services of Dr Herbert Jones medical officer of health for the Herefordshire combined districts who is retiring on account of ill health

*£5 5s.*—Dr J. B. Jenkins (Rhondda) Sir George Newman, K.C.B.

*£3 3s.*—The Editor of the *Medical Officer*

*£2 2s.*—Messrs. Ainslie and Hepper (Hereford) Dr J. R. Bulman (Hereford), Dr Meredith Young (Chester)

*£1 1s.*—Drs. E. H. Baldock, A. Middleton Brown, M.O.H., W. B. Butler, Prof. J. T. Cash, E. W. DuBuisson, H. E. Durham S. L. Corry Hugh Fenton, Cyril Francis, J. Oswald Lane, J. H. Lilley Peter Lowe M.O.H. F. S. Machin, Ian W. McGregor R. Wood Power, J. A. Prichard, B. W. Stallard, F. H. Thompson Lieut.-Colonel Wanhill (all of Hereford) Dr. Basil Adams (Newport Sanatorium) J. Ridley Bailey (Bilston), T. W. Barlow O.B.E. J. Blackett (Bath); G. F. Buchan (President of Society of Medical Officers of Health); W. H. Cam (Ross) S. Child (Horsham) H. C. Clark (Wellington), J. Stephenson Clarke (Weobley); Alfred Cox, O.B.E. (Medical Secretary, B.M.A.) W. Allen Daley (Hull); G. R. Darling (Eardisley) W. R. Darroll (Leintwardine) W. S. Davies (Bristol), G. W. Dryland (Kington); A. B. Dunne (Doncaster) C. D. Edwards (Kington); H. R. R. Fowler (Ledbury) R. P. Garrow (Chesterfield) A. Ll. B. Green (Ross) T. L. Hall (Dilwyn), Prof I. Walker Hall (Bristol), Richard Harding (Kington), Mr W. L. Hempson (Tunbridge Wells); Drs. F. C. H. Home (Tarrington) W. J. Howarth (London) C. W. Hutt (London) T. A. Jones (Ledbury) H. V. Lamb (Leominster) A. W. McMichael (Vowchurch) J. W. Miller (Llandrindod Wells) E. A. Milner (Kington); W. H. Morgan (Ewyas Harold); Sir Arthur Newsholme, K.C.B. Drs. Thomas Orr (Ealing); Norman H. Pike (Cheltenham) H. B. Pope (Clifton) A. L. Porter (Reigate) K. G. Salmon (Finsbury Park), Charles Sanders (Carshalton) J. Grimmond Smith (Burghill); E. H. Snell (Coventry) John Steed (Staunton-on Wye); Gerard Steel (Leominster) J. Lionel Stretton (Kidderminster), A. S. Underhill (Barnes); E. Walford (Walmer) A. M. Watts (Broadstairs) James Wheatley (Shrewsbury) E. G. H. Williams (Colwall) Mary Williams (Colwall) J. B. Yeoman (Birkenhead); per Dr J. B. Jenkins—Dr W. E. Thomas Messrs Octavius Thomas, Evan Llywelyn J. Tony Davies, Gwilym Reed and James Williams (all of Rhondda).

*£1*—Prof. A. E. Boycott, F.R.S. (London); Dr T. F. Dewar (Edinburgh)

*10s. 6d.*—Drs A. M. Humphry (Pontrilas); W. M. Lucas Johnstone (Newent) W. A. Murphy (Brymenin).

The fund will remain open until the end of May Subscriptions should be sent to Dr John Steed Staunton-on Wye, Hereford.

THE Home Secretary has appointed Lieut.-Col. John Allan Anderson, M.B., to be an inspector for the purpose of the Cruelty to Animals Act, 1876.

Dr. Henry Renney, medical officer of health for the borough and port of Sunderland, died on April 24th, after several months' illness, at the age of 66.

HULL ROYAL INFIRMARY.—At the annual meeting of Hull Royal Infirmary it was stated that of the total number of 37,334 patients treated in 1925, 20,048 were casualty cases. This is 54 daily, and 2563 more than in 1924. A scheme has been approved for enlarging the infirmary at a cost of £80,000.

GRESHAM COLLEGE.—Sir Robert Armstrong-Jones will deliver lectures on Physic on May 4th and the three following days at 6 P.M. at the Gresham College, Basinghall-street, London, E.C. The subjects of the lectures will be Tumours and Cancer, Arthritis and Rheumatism, Venereal Diseases, and Sleepy Sickness, and they will be open to the public.

LADIES' MEDICAL GOLFING ASSOCIATION.—The spring meeting held at Northwood Golf Club on April 27th was well attended. The Canny Ryall Cup was won by Dr. Joan Ross (99—24=75). Miss Edith Leitch won the scratch prize with a score of 84. Handicap prizes were given in three divisions as follows: Senior division, Mrs. Lewis Smith (86—8=78); second division, Mrs. F. de Paula (89—13=76); third division, Mrs. Dobell (106—28=78). Greensomes were played in the afternoon, the winning couple being Mrs. de Paula and Mrs. Hunter.

STRASBOURG: POST-GRADUATE COURSES.—A post-graduate course on Cancer is to be held by the medical faculty of Strasbourg from Oct. 18th to Nov. 6th, under the direction of Dr. Gunsett, director of the Centre anticancéreux, Hôpital Civil, Strasbourg, from whom particulars may be obtained.—A course on Pulmonary Tuberculosis and Diseases of the Respiratory Tract is also to be held by the faculty from Oct. 8th to 23rd. It has been arranged by Prof. G. Canuyt and Dr. E. Vaucher, and applications should be made to the latter at 8, quai Finkwiller, Strasbourg.

DONATIONS AND BEQUESTS.—The late Baron Leith of Fyvie left by will £1000 to Fyvie Cottage Hospital.—The West Kent General Hospital has received £1000 from Mr. George Foster Clark for the endowment of a cot in the children's ward to be called the George Foster Clark Cot. This sum was presented to Mr. Clark by the National Farmers' Union for his services as Hop Controller.—Mr. Charles Julius Meyer, barrister-at-law, Wallasey, Cheshire, left £2000 to the Victoria Central Hospital, Wallasey.—Mr. William George Lofthouse, Garston, Liverpool, gave on the death of his wife £2000 to Sir Alfred Jones Memorial Hospital to endow two beds, and £100 to the Garston and District Nursing Association.

SMOKE ABATEMENT IN MANCHESTER.—Dr. Veitch Clark, the medical officer of health of the city, has presented a report to the Public Health Committee regarding legislation for the abatement of the smoke evil. Any new smoke abatement Bill, he says, ought to ensure that dense smoke of any colour shall per se constitute a nuisance, of which no defence provided in other sections of the Bill shall be permissible; also that, apart from the penalty imposed on the first hearing of the case, there shall be a daily penalty of £10. As reheating, annealing, hardening, and forging of iron have been carried on in Manchester for many years without the production of dense smoke, it is recommended that none of these processes should be included in any modification of the regulations. Another suggestion is that the Government be requested to take into consideration the possibility of dealing with the smoke nuisance on the same lines as has been adopted in dealing with sewage—that is, by the provision of smoke boards with similar powers and duties to those imposed upon river boards.

CLOSING OF CANTON HOSPITAL.—We have received from Dr. James L. Maxwell, the executive secretary, on behalf of the Executive Committee of the China Medical Association, an official statement of the circumstances under which this hospital was forcibly closed at the beginning of March by the Miscellaneous Workmen's Labour Union of Canton. The Union demanded, among other things, an increase in the wages of all the workmen employed by the hospital; that no man should be dismissed without its approval; that when he was he should be paid a month's wages as a solatium; and that only members of the Union should be employed. The authorities of the hospital, which is "a private life-saving charitable institution," the working expenses of which last year exceeded the receipts by $20,000, refused these demands, thereupon the hospital was summarily closed by the Union. Light and water were cut off, and the sick inmates turned into the streets.

# Medical Diary.

## SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, May 3rd.—8.30 P.M., SOCIAL EVENING. 9.30 P.M., Sir Humphry Rolleston will give an illustrated address on Some Worthies of the Cambridge Medical School.

TUESDAY.—8.30 P.M., ORTHOPÆDICS (Cases at 5 P.M). Annual General Meeting. Cases: Mr. Paul Bernard Roth: 1. Congenital Radio-ulnar Synostosis, occurring in Three Children in One Family, two of them with Absent Patellæ. 2. Case of Madelung's Deformity. Other cases will be shown.

WEDNESDAY.—8.30 P.M., SURGERY. Annual General Meeting. Dr. W. E. Gye: The Origin of Tumours.

THURSDAY.—8 P.M., OBSTETRICS AND GYNÆCOLOGY. Annual General Meeting. Short communications: Prof. H. Briggs: Pregnancy and Ascites. Dr. Herbert Spencer: Two Cases of Adeno-fibroma of the Ovary. Mr. F. J. McCann: A New Method of Cæsarean Section. Dr. J. Ford Anderson: On Total Transposition of the Viscera and its Clinical Importance.

FRIDAY.—5 P.M., LARYNGOLOGY (Cases at 4 P.M.). Annual General Meeting. Epidiascopic Demonstration by Dr. W. Jobson Horne. Cases will be shown by Mr. H. Bell Tawse, Dr. Dan McKenzie, Mr. Norman Patterson, Mr. F. J. Cleminson, Mr. Leslie Powell, and others. 7 P.M., ANÆSTHETICS. Annual General Meeting.

SATURDAY.—10.30 A.M., OTOLOGY (Cases at 9.45 A.M.). Annual General Meeting.

SATURDAY AND SUNDAY.—BALNEOLOGY AND CLIMATOLOGY. Annual Provincial Meeting at Llandrindod Wells. Fellows and Members who wish to attend should communicate with Dr. Ackerley, Llandrindod Wells, before May 6th, so that arrangements may be made with the Railway Company and for the hotel.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

TUESDAY, May 4th.—5 P.M., Prof. H. MacLean: Carbohydrate Metabolism in Health and Disease (First Oliver-Sharpey Lecture).

THURSDAY.—5 P.M. (last Oliver-Sharpey Lecture).

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, May 3rd, to SATURDAY, May 8th.—Special afternoon demonstration in clinical surgery at the St. Mark's Hospital for Diseases of the Rectum on Wednesday, at 2.30 P.M.—CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C. Clinical and operative intensive course, first week.—LONDON LOCK HOSPITAL, Dean-street, W. Clinical work daily and formal lectures throughout the week as per syllabus.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. Special course in children and women's diseases.—ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, Charing Cross, W.C. Afternoon course; clinical work daily and three demonstrations per week.—MAUDSLEY HOSPITAL, Denmark Hill, S.E. Lectures and demonstrations pertaining to Psychological medicine. Further information from the Secretary of the Fellowship of Medicine.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, Leicester-square, W.C.

TUESDAY, May 4th.—5 P.M., Dr. H. W. Barber: Alopecia Areata and Vitiligo.

THURSDAY.—5 P.M., Dr. A. M. H. Gray: The Sarcoids and Lupus Pernio.

ST. MARY'S HOSPITAL INSTITUTE OF PATHOLOGY.

THURSDAY, May 6th.—5 P.M., Prof. J. Barcroft: Recent Work on the Spleen.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, May 4th.—4.15 P.M., Mr. S. R. Wilson: Demonstration of the Use of Ethylene.

FRIDAY.—4.15 P.M., Dr. R. S. Paterson: X Ray Investigation of the Intestinal Tract.

ANCOATS HOSPITAL POST-GRADUATE LECTURES, Quay-street.

THURSDAY, May 6th.—4.15 P.M., Mr. McEvedy and Dr. Twining: The Surgical Dyspepsias.

MANCHESTER AND SALFORD HOSPITAL FOR SKIN DISEASES POST-GRADUATE COURSE.

THURSDAY, May 6th.—4.30 P.M., Dr. Gibson: Dermatological Therapeutics.

SHEFFIELD UNIVERSITY POST-GRADUATE CLINICS.

FRIDAY, May 7th.—3.30 P.M. (at the Royal Hospital), Prof. Hall: Medical Cases.

# Appointments.

HALL, Prof. A. J., M.D. Camb., F.R.C.P. Lond., has been appointed Consulting Physician to the South Yorkshire Mental Hospital.

PEIRCE, E. R., M.R.C.S., L.R.C.P. Lond., an Assistant Port Medical Officer in Liverpool.

SIMPSON, G., M.B., B.S. Melb., M.R.C.P. Lond., Assistant Resident Medical Officer to Queen Charlotte's Maternity Hospital.

# Vacancies.

*For further information refer to the advertisement columns.*

*Beit Memorial Fellowships for Medical Research*—Jun. Fellows. £350

*Birmingham, Selly Oak Hospital.*—Res. Jun. Asst. M.O £300

*Bradford Royal Eye and Ear Hospital.*—Res. H.S. £120

*Brighton, Royal Sussex County Hospital*—H.S. £150

*Bristol University*—Lecturer in Forensic Medicine and Toxicology Also Lecturer in Public Health.

*Cancer Hospital, Fulham-road, S W*—H.S. At rate of £100

*Cardiff, Royal Hamadryad Seamen's Hospital.*—Hon. Consulting P

*Central London Throat, Nose and Ear Hospital, Gray's Inn road, W C*—Hon Asst. Out-patient Reg

*Chester County Mental Hospital.*—Fourth Asst. M.O £300

*Dagenham Sanatorium, Dagenham, Essex*—Asst. M.O £250

*Dublin, St. Vincent's Hospital.*—Asst S. to Out patient Dept.

*Durham County Mental Hospital*—Second Asst. M.O £500

*Fulham Metropolitan Borough*—M.O H £1100

*Greenwich, Dreadnought Hospital.*—Med. Supt. £300

*Hampstead General and North West London Hospital, Haverstock Hill N W*—H.S. and Cas. Surg. O. Each at rate of £100

*Shrewsbury, Eye, Ear and Throat Hospital for Shropshire and Wales.*—H.S. £200

*Swansea General and Eye Hospital*—Sen. Res. O £350 Also H.P £150

*Throat Hospital, Golden square, W*—Res. H.S. £100

*University College Hospital, Gower-street W C*—Harker Smith Reg £250, Also Obstetric Reg £135

*Walthamstow, Wanstead, and Leyton Hospital, Orford-road, E*—Jun. H.S. At rate of £100

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Carnarvon (Carnarvonshire)

# Births, Marriages, and Deaths.

## BIRTHS.

McGRIGOR.—On April 16th, at Welbeck street, W, the wife of Major D B McGrigor O B.E., R.A.M.C., of a daughter

MORLEY.—On April 27th at 8, Burlington road, Withington, Manchester, to Mr and Mrs John Morley—a daughter

OLDHAM.—On April 13th at Calton Cottage, Morecambe, Lancashire, the wife of Dr T V Oldham of a son and a daughter

## MARRIAGES.

MELVILLE—RUSSELL.—On April 10th, at the Parish Church, Stoke-in Teignhead, South Devon, William Spence Melville, M B., Ch.B., to Mabelle Annie, only daughter of Arthur B. Russell, of Dunmore-road Wimbledon.

WALKER—WILSON.—On April 24th, at All Saints, Fulham, Kenneth Macfarlane Walker, F R.C.S., to Eileen Marjorie Wilson only daughter of Mr and Mrs. F H Wilson, of Marlborough Mansions, Cannon hill, N W

## DEATHS

HAMILTON.—On April 20th, at his residence, Brentwood, Prestwich Park, Manchester, Thomas Hamilton, L.R.C.P., M.R.C.S.

HOPE.—On April 18th at Southsea, John Hope, M.D., L.R.C.S. Edin., formerly of Chobham, aged 86 years.

JOHNSTON.—On April 23rd, at a nursing home in London, Col Charles Arthur Johnston, C.B., D S.O., I.M S., aged 59.

MAURICE.—On April 22nd at Craven-road, Reading, William James Maurice, M.B Oxf., aged 68

WHITE.—On April 10th at the Barn House, Chinnor, Oxon., Edgar Ramsay White, F R.C.S., late of Deal

*N.B.—A fee of 7s. 6d is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Comments, and Abstracts.

## APPLICABILITY OF DREYER'S ANTHROPOMETRIC FORMULÆ TO BOYS.

### BY D CARADOG JONES.

STATISTICS of height, weight, and chest girth have been collected and their relations studied scientifically from the time of Quetelet onwards. Indeed, he may be regarded as the founder of anthropometry. *Measurements* of vital capacity—the amount of air an individual can expel from his lungs after a deep breath—were added when Hutchinson began his work. Many formulæ have been proposed by various writers to connect weight with height, vital capacity with weight, and so on. Among the most attractive of recent date are those due to Prof Dreyer, of Oxford.

Under the title of "The Assessment of Physical Fitness" Dreyer has published tables which aim "*to supply medical men and others interested in the subject with a method . . . whereby physical fitness can be assessed on the basis of a few simple measurements.*" These tables depend (p 20) upon the following ratio formulæ for determining V (vital capacity) from W (weight) and λ (stem length, or height of trunk alone) in the case of males:—

$$V = W^{0.72}/0.69 = \lambda^{2.257}/0.1172$$

—i.e, formulæ of the type

$$V = W^n/K,\ V = \lambda^n/K,$$

in which n and K are called "constants" by Dreyer. When in the above formulæ approximate values are substituted for n—namely, ⅔ for 0·72 and 2 for 2·257, he found that they became

$$V = W^{\frac{2}{3}}/0{\cdot}360 = \lambda^2/1{\cdot}90.^*$$

In his table-book Dreyer states: "While it cannot be claimed that the constants employed . . are to be regarded as fixed and final, it can be stated that any changes they may have to undergo in the future, as a result of the further accumulation of data, in normal adolescents . . . will be small and not likely to impair their present validity from the practical point of view" It will be noted that the author, in the passage quoted, appears to limit the application of his ratios to normal adolescents, but on the next page he remarks that 'for the range of indices given, it has been found that the question of age is of little or no importance up to an age of about 50 years.' Moreover, out of ten examples to illustrate the use of the ratios, at the end of the same book, he takes one male aged 8 years, one aged 9, two aged 13, and one female aged 9; also, in a study of *pulmonary tuberculosis*† he applies the ratios in several instances to quite young boys and girls. It is therefore important to consider the foundation on which the constancy of the K's rests and with that in view I have tested it on the average measurements of a number of boys between the ages of 11 and 19 in a large grammar school.

The original data which led to the adoption of these ratios by Dreyer were the result of observations made on "16 men and boys who were carefully selected on account of their physical fitness and covered as widely different a range in weight, height, &c., as possible"; their ages varied from about 13 to 52 years.‡ In the same paper the author adds that "before accepting these constants" (i e., the values he had found for the n's and K's in the case of the 16 men and boys, and in a few other groups to be noticed presently) "as valid standards, it became important to see how they would compare with the constants that could be obtained from Schuster's extensive series of measurements of vital capacity in 959 Oxford undergraduates." He then proceeds to calculate from Schuster's data the K's in the ratios

$$K = W^{0.72}/V;\ K_1 = W^{\frac{2}{3}}/V;\ K_2 = \lambda^2/V.$$

Table I, the details of which are taken from THE LANCET article quoted above, exhibits the result of such calculations for Dreyer's *own groups* as well as for the Oxford data.

The striking fact about this table is the practically exact agreement between the values for the K's in the first and last groups, since Schuster's observations were quite independent of Dreyer's On examining Schuster's data, however, it is found that certain allowances had to be made before calculating the ratios:—

(*a*) The weight in Dreyer's ratios is not weight without clothing, whereas Schuster weighed his men *fully dressed* but without boots and without coats. For this Dreyer appears to have allowed weights varying from 2650 to 2700 g. in Schuster's six age-groups; the average allowance, weighted according to numbers in the different age-groups, is 2720 g. or 6 lb. almost exactly.

---

* THE LANCET, 1919, ii, 229

† Ibid., 1920, i, 1212.

‡ Ibid., 1919, ii, 227.

(*b*) Dreyer measured the stem length in a perfectly definite manner. Schuster seems to have measured the sitting height, though only the figures for full stature and length of leg are given in the account of his observations in *Biometrika* (vol. viii.). By subtracting the one from the other we get the body length which exceeds the number taken by Dreyer for stem length at each age by 2·7 cm. This deduction is presumably necessary to make the two methods of measurement comparable.

(*c*) Dreyer took five measurements of V for each person and chose the highest of the five readings, whereas Schuster took three readings and chose their mean. Dreyer himself states that in a large number of observations he found the highest reading was about 5 per cent. greater than the mean of five readings.

I have re-calculated the K's for Schuster's data: (*a*) making an exact allowance of 6 lb. for weight of clothes in each age-group, (*b*) accepting Dreyer's reduction of Schuster's figures to get the stem length, and (*c*) adding 5 per cent. to Schuster's figures for vital capacity. Table II. shows my results for each age-group, and I have included for comparison the values of the same constants for eight groups of boys, 1110 in all, varying in age from 11 to 19 years. The last row of Table II. differs appreciably from the last row of Table I.

Table I.—*The K Constants in Dreyer's and Schuster's Observations.*

| No.* | Description of group. | $K = W^{0 \cdot 72}/V$ | $K_1 = W^{\frac{2}{3}}/V$ | $K_2 = \lambda^2/V$ |

It is clear from Dreyer's own observations that the K's vary with the class to which the ratios are applied (see, for example, Table I.). This he himself admits, and he uses the variation to differentiate between one class and another as to physical fitness. My concern here is to point out that, *even in dealing with the same class, the K's are not constants: they are functions of age as well as of class.* To prove this, the 1110 boys have been arranged in age-groups and the mean values of W, V, and λ found for each group; the resulting K's are seen to decrease as the age increases, and it is particularly noteworthy that the values where one set of observations (grammar school-boys) ends agree closely with the values where the other set of entirely independent observations (Schuster's undergraduates) begins.

The conclusion to which we are led is that, in the ratio formulæ discussed, expressing V in terms of W and in terms of λ respectively, the so-called "constant" K is really a function of the age of the subject; prior to full maturity, at all events, K tends to decrease as age advances.

Another formula used by Prof. Dreyer, relating weight to stature, seems to be subject to less variation with age in dealing with the averages of large numbers (see *Nature*, April 10th, 1926; also a complete account of Dr. Mumford's work at the Manchester Grammar School concerning health and growth, to be shortly published).

I am indebted to Miss P. M. Borthwick, on the staff of Manchester University, for kindly verifying all my calculations; and to Dr. Alfred Mumford, medical officer of Manchester Grammar School, for the data relating to boys.

## THE MEDICAL SITUATION IN CHINA.*

By H. Jocelyn Smyly, M.D. Dub., F.R.C.S. I.,

PEKING UNION MEDICAL COLLEGE.

A report published by a Commission sent to China by the Rockefeller Foundation in 1914 to make a survey of medical conditions, stated that outside the Treaty ports there was practically no modern medical service except that of the mission hospitals. This remains substantially true to-day, the reason being that although Chinese are returning in increasing numbers to their own country, equipped with a training in modern medicine gained abroad, they find ample scope for their service amongst their compatriots in such places as Shanghai and Tientsin; whereas, the inhabitants of the inland cities are not yet sufficiently convinced of the value of these methods to pay the large cost of modern hospitals, nor to commit themselves to the care of a scientific physician without simultaneously calling in as many of the old style practitioners as they can afford to pay. In these circumstances the mission hospital, in addition to the primary religious purpose which it is founded to promote, is a pioneer also in scientific practice, and it unquestionably provides the young Chinese doctor outside of the modern cities with the best, if not the only, opportunity for giving in an adequate way the service for which he has been trained.

It is true that in the past, and to a great extent to-day, these hospitals have been lamentably ill-equipped owing to lack of funds, but a general steady improvement in their efficiency is being made, and a certain number are excellent examples of what a modern hospital should be; they are housed in good buildings, provided with a regular nursing service, a laboratory, operating and X ray plant, and have good sanitation, kitchen and laundry. The Americans take a lead in such development, but some British hospitals hold a good position in this category, such as the new S.P.G. Hospital in the city of Tatungfu in the inland province of Shansi. Their effectiveness and the measure of local support which they receive is largely proportional to the efficiency of their organisation and the amount of foreign money invested in them. This example is being followed by enlightened Chinese, who have erected a thoroughly up-to-date model hospital in Peking, and others in Canton and Shanghai.

For the provision of modern medical service to the country as a whole, medical schools are essential. A certain number of Chinese schools are in existence, but although they are improving they are, on the whole, of a low standard. The missionary forces at work in the country have also about half a dozen medical schools. The best of these is at Tsinanfu, Shantung. This school, while not first class, gives a good training and is steadily improving year by year. It is operated by a group of nine missionary societies—four British, one Canadian, and four American—and is incorporated under a Canadian charter. The faculty numbers 28, and, including nursing and house staff, there is a total full-time qualified staff of 51. The annual cost, including salaries, is £21,000.

In Peking the Rockefeller Foundation has a medical school, the Peking Union Medical College. This institution, originally founded in 1906 by missionaries, maintains its connexion with the six missionary societies who originally conducted it; it is owned and supported, however, by the Rockefeller Foundation. The college is palatially housed and liberally equipped with every provision for scientific teaching and research. There is a full-time medical teaching staff of about 60, in addition to the resident medical staff of the hospital, a nursing school, and the administrative departments. The annual cost is about £160,000, including salaries. Each of these schools has about 100 students, and both are co-educational.

Public health work is coming to be recognised as one of the most important lines of development in medical work in China. In this again missionaries have been for several years the pioneers. A union of six organisations—the Y.M.C.A., Y.W.C.A., China Medical Association (Missionary), National Medical Association (Chinese), China Christian Educational Association, and the Nurses' Association of China—has organised a council on public health education in Shanghai under the direction of Dr. W. W. Peter. This body works mainly, as its name implies, in popular education in hygiene, taking the schools as its most effective sphere for propaganda. It also carries out and stimulates the routine examination of students, and other work. Occasionally it makes its appeal to the masses, as, for instance, in Foochow following an epidemic of cholera in 1919, when the number of cases was estimated at 10,000 with a severe death-rate. A local committee, with the advice and assistance of the Council on Health Education, organised a week of publicity in June, 1920; 217 meetings were held, at which 110,000 by count were present. In addition a parade traversed 90 per cent. of the main thoroughfares for six days presenting in striking exhibits, mounted on floats, the right and wrong ways of dealing with water, food, and human excreta. As a result only a few sporadic cases of cholera occurred that summer, which investigation showed to have been brought in from outside. There was cholera north and south of Foochow and in Formosa across the Straits.

---

* Being an abstract of an address delivered at a meeting of the Society for the Propagation of the Gospel held on April 21st.

An appeal has been issued by the National Medical Association (a purely Chinese association of modern physicians), meeting in conference in Shanghai last February, which is worth quoting. Among the resolutions passed were the following:—

> That the National Medical Association of China hereby expresses its great appreciation to the British Government and people for the return of their share of the Boxer Indemnity, and at the same time expresses the hope that a substantial portion of the fund may be allocated for the specific purpose of promoting public health activities in China.
>
> That since Great Britain has been a pioneer in the field of public health, whose present leadership is attested by the low mortality and morbidity rates, by the development of the most modern public health practices and governmental machinery culminating in the establishment of a Ministry of Health, the Chinese people may confidently look to Great Britain for guidance and help in promoting public health in China.

These resolutions were passed following an address by Dr. F. C. Yen, brother of the Minister-elect to Great Britain. It is to be hoped that they will receive favourable consideration from the Commission appointed from this country to decide on the appropriation of the return portion of the indemnity.

## POLAND, TO-DAY AND TO-MORROW.

FEW nations have received more sympathy than Poland, but seldom has sympathy been so ineffective. To the Englishman the country is inexpressibly remote and its political position since the war has unfortunately done little to foster understanding or encourage everyday coöperation. On another page we record the opening of a school of hygiene at Warsaw and quote the sentiments which animate the public health authorities in Poland. The development of a health policy is only one of the ways in which a nation once great is striving to regain the civilisation of which it has been baulked, and it is in every way desirable that something of the progress made and forthcoming should be understood in this country. We welcome, therefore, the appearance of "The Polish Handbook" (published in English from 17A, Portland-place, London, W. 1, at 10s. 6d. net), which contains a good map and some 700 pages of well-arranged and readable information. This "guide to the country and resources of the Republic of Poland," printed by Eyre and Spottiswoode, Ltd., is just what is wanted to interest business men, travellers, or ordinary people in the Poland of to-day. Its editor apologises for gaps in the information provided, but this is inevitable in describing a State which has been in independent existence for only six years; and with him we hope that a second edition will soon give an opportunity of remedying defects. Much information of interest to medical men will be found in the sections on public health, housing, and labour and social welfare.

## R.A.M.C. TRAINING MANUAL.

THE teaching of the Royal Army Medical Corps was so sound that much of it survived the test of the Great War. The latest edition[1] of the Training Manual contains new matter on gas poisoning, carriage of stretchers on the shoulder, convalescent camps, and aseptic surgery. In the previous issue two reasons for the existence of the Corps were given: (1) the prevention of disease and (2) the care and treatment of the sick and wounded; to these are now added (3) the collection and evacuation of sick and wounded, and (4) the preparation of professional records about them. These four purposes are kept steadily in view all through the Manual, and it is further impressed on all ranks that they must not only take the greatest care of their wounded comrades, but forthwith record their names, lest they lose pensions; not only do their best to preserve the persons of their patients, but also their personal effects, of which a careful list must be made at once to save trouble later. The account of the new organisation of the Corps in war is clearly detailed, and the reader in search of examples will find them in the Medical History of the War. The paragraph on food values disappoints. Is it much use to an orderly to know that carbohydrate and protein yield 4, fats 9 calories per gramme, when he is not told the composition of the foods which are given in ounces? The U.S. Navy Hospital Corps Handbook does better than this. The old picture of intestinal villi has gone, and instead there is a good picture of the teeth, and a page of valuable advice on dental hygiene. The book is a clear statement of guiding principles and well worth its modest price.

## AFRICAN MEDICAL REMEDIES AND CHARMS.

THE department of pharmacology of the University of Witwatersrand some time ago began a detailed investigation into the medicinal value of plants and other materials. The head of the department, Prof. J. M. Watt, sent out several thousand questionnaires to all parts of the sub-continent, inviting any who were interested to submit specimens. His most sanguine expectations have been exceeded; from Northern Rhodesia alone no fewer than 1000 specimens have been received, and they have come in from all over the Union and from distant parts. The object of the investigation is to ascertain the value of charms, poisons, and homely remedies, with the idea of finding some whose virtues are at present unknown to the medical profession. It will take time to deal with the material now available and no results of this interesting study are likely to be published in the near future.

## THE HANDWRITING OF MEDICAL MEN AND STUDENTS.

*To the Editor of* THE LANCET.

SIR,—Might not the examining boards, or the General Medical Council, be warned by *Punch* this week and do something to try and improve the handwriting of medical men and students? This thought will probably have occurred to others besides myself. Very few of us always write a good and legible hand, and many of us often write badly; but others *invariably* write so very badly that they thereby cause their fellow-men much trouble and loss of time. Consultants often waste much valuable time in trying to read the letters, and especially the names, of medical men who have written to them for appointments. They are often obliged in the end to cut out the signature of the medical practitioner from his letter and to gum it on their reply envelope. Also, general practitioners are often annoyed by badly-written prescriptions from consultants, which they cannot possibly make out; and it is left for the dispensing chemist to do the best he can. This bad writing often leads to mistakes; some irritating, others amusing, others serious.

Examiners in reading over the final examination papers not infrequently meet with papers which are so very badly written that in many parts they are illegible. Yet these candidates have passed the entrance examination in general education and the ability to write a legible hand ought to be one of the requirements of such examinations. Students should remember that if they do not take the trouble to write a legible hand, examiners may not take the trouble to read all parts of their papers, and hence many marks may be lost. Examiners have usually to read through a large number of papers in a very limited time, and if a candidate's writing is so bad that it can only be made out by the use of a lens, or by prolonged consideration, it is evident that however patient the examiner may be, he is obliged, by time-limits, to pass over the very badly-written parts of the answers. (Another common defect is the frequent use by candidates of abbreviations, such as A.H., A.M.P., &c., which are often puzzling at first sight.)

It is difficult to know how to deal with these extremely bad writers. But so many of them could become good writers after lessons with a writing master for a short time; and this would be of great service to them for the rest of life. One British examining board has a regulation that marks will be deducted for bad writing; but candidates who have written badly will not know of the reduction in their marks, and will make no efforts to improve. If examining boards were to make a regulation that their examiners when sending up the results of the final examinations should report those candidates whose writing was extremely bad, then these men might be asked to take lessons from a writing master, and to give evidence that they can write a more legible hand before the degree or diploma is granted. Or the examining boards might report to the General Medical Council the names of successful candidates whose writing was extremely bad; and the Medical Council might then do good service to the community by requiring these men to take lessons from a writing master, and to give evidence that they can write a more legible hand before their degrees or diplomas are registered.

---

[1] Royal Army Medical Corps Training, 1925. H.M. Stationery Office. 1925. Pp. 383. 1s.

Such regulations would do much to strongly impress on these bad writers the necessity for writing a more legible hand; and many bad writers might be converted into good writers. Many mistakes and much trouble would be thereby avoided, and the regulations would be of great service, both to the men themselves and also to the community.

I am, Sir, yours faithfully,
April 16th, 1926. R. T. W.

⁂ A medical officer of the Scottish Board of Health has just called the attention of insurance practitioners in Dundee to the illegibility of certification forms which they have filled in for panel patients. Each form, says this officer in his report, is a cheque presented for payment by the drug fund, and he adds: "With such scrawls as these, in many cases it is quite impossible for the clerk to the committee to say who the drawer is meant to be, and whether he is an insured person."—ED. L.

## ADRENALIN FOR PARAPHIMOSIS.

*To the Editor of* THE LANCET.

SIR,—The use of adrenalin in cases of paraphimosis is not perhaps as widely known as it should be. Hence the necessity for the note of "M.B." in your issue of March 6th (p. 530). I have been using this drug in cases of paraphimosis for the last two years and it has never failed in any case so far. I first came to know the use of this drug in "Clinical Memoranda" by Brand and Keith. The authors of this book advise to wrap the end of the penis, including the strangulated band, with a compress of absorbent cotton-wool soaked in a mixture of equal parts of adrenalin chloride (0·1 per cent.) and cocaine hydrochloride (10 per cent.). The compress is kept in place for about 15 minutes by a bandage with a moderate amount of compression. On removal of the compress the œdema will be found to have completely disappeared and with a little traction the prepuce can be restored to its normal position.

I am, Sir, yours faithfully,
YOGINDRA DEVA, B.Sc., M.B., B.S.
Fyzabad, India, March 31st, 1926.

## RAT DESTRUCTION.

IT is not a very big step from the appointment of a professional rat-catcher to the appointment of an economic biologist to supervise, as a sanitary inspector, the destruction of rats and mice; and considering the damage done by rats it is a wonder that the step was not taken long before the Rats and Mice (Destruction) Act, 1919, came into force. In a recent small book (A Practical Handbook of Rat Destruction. London: John Hart, 1926), Mr. C. L. Claremont quotes authorities who state that in this country rats probably cost about £70,000,000 per annum, while in India the total losses due to the spread of plague and other incidental activities of rats amounted to £828,000,000 in a period of 20 years. The common brown rat and the black or ship rat are the two varieties commonly met with in this country, and apart from certain important prophylactic measures concerned with building, the practical methods of rat destruction are comprised under the headings of hunting, trapping, gassing, poisoning, and artificial infection with disease—the virus method. Mr. Claremont discusses all these methods in detail, adding a useful appendix with formulæ of baits. He also sets out measures for coöperation in rat destruction by the various authorities concerned. The book should be of great interest to all public health workers and of service to those concerned in rat destruction.

## MANCHESTER HOSPITALS AND INSTITUTIONS.

St. Mary's Hospitals treated over 17,000 patients in 1925. The income was £32,256, the patients contributed £6787, and there was a deficit of over £11,000. At least £6000 will be needed for the new nurses' home in Victoria Park, and £3000 per annum is required to keep up the 20 extra beds and 18 babies' cots for which room can now be found at the Whitworth-street Hospital.—The Manchester Radium Institute treated 6479 patients in 1925 as against 4903 in 1922. Attention has been called to the meagre response of the public, not only of Manchester but of Lancaster, to the annual subscription list. The Institute, it is remarked, cannot keep going on £250 a year. A donation of £4000 has been received from the trustees of the late Colonel Barlow, of Bury. Radium now costs £12 per mg., but it cost £28 per mg. at the time when the Institute paid for most of its £35,000 worth of stock.—At a meeting of the Incorporated Accountants on April 14th Mr. B. B. Ormerod, managing director of the Family Medical Services, Ltd., spoke of the need of a middle-class hospital for Manchester which could be run on similar lines to St. Chad's Hospital at Birmingham.

## WHO'S WHO.[1]

THIS is a belated review, but if it is assumed that, before a work should be criticised, it should be read from cover to cover, there is nothing dilatory about a notice in April of the 1926 edition of "Who's Who," published in January, for the work now contains over 3000 pages. It is probably more often used in newspaper offices than any other book of reference, and it is in those offices that its inclusive nature is particularly appreciated. Many cynical comments have been made upon the relative space which autobiographical contributors allot to themselves, and it is a fact that comparatively unknown followers of divinity, medicine, and law, and many civil servants and officers in the Services obtain in "Who's Who" fuller notice than is claimed by, say, Mr. Stanley Baldwin or Signor Mussolini. But it is the less widely known people concerning whom the journalist wants to have information, so as to form an estimate of their right place when their names occur in connexion with any public proceedings or developments. It is quite important in commenting upon current events to know whether the protagonists of any movement, the critics of any policy, the belauders or denouncers of any departure possess adequate qualifications for expressing an opinion. Speaking for medical journalism, if to the general newspapers a communication is made announcing dogmatically the discovery of a way to prevent, to avoid, or to cure cancer—not an unusual occurrence—it is convenient to ascertain from the columns of "Who's Who" what recognised position the author possesses enabling him to disseminate the glad tidings. The book remains a thoroughly valuable annual in which necessary information is given in a very convenient form.

## OXYGEN AND ANÆSTHESIA.

THE third of the series of post-graduate lectures on General Anæsthesia, delivered under the auspices of the Dental Board, was given by Dr. Leonard Hill and appeared in the *British Dental Journal* of April 15th. A large part of the lecture was devoted to a convincing explanation of the dangers associated with chloroform and should be highly valuable in dissuading any dentists, if such there be, who still regard that drug as a suitable anæsthetic for common use in dental work. The physiological aspect of the anæsthesia produced by ether and by nitrous oxide, as well as that of ethylene, was also described. Dr. Hill would apparently like to see advantage taken of the enhanced effect of nitrous oxide and oxygen when given under an increased atmospheric pressure. He suggests that a suitable chamber might easily be constructed from part of a tube railway. We hope his remarks on this subject will catch the eye of some enterprising philanthropist; an easy road to fame appears to await him if he endowed the hospitals of London with "gas tubes" associated with his name. The all-important lesson—to avoid oxygen shortage in inducing and maintaining anæsthesia—was forcibly instilled into the minds of his hearers in more than one portion of Dr. Hill's valuable lecture.

## ON PREPARING THESES AND TECHNICAL PAPERS.

THE average candidate finds the task of writing a thesis one of the hardest obstacles placed in the path of qualification by his examiners. To all who see it looming ahead of them we commend an essay[2] by Sir Humphry Rolleston, which gives invaluable advice on the choice of a subject, the way to master it, and the best means of composition. Too commonly candidates are content to face their difficulties one at a time, but in this exceptional case it is worth while to meet trouble half way. Even in the comparatively early days of clerking or dressing, as Sir Humphry Rolleston points out, it is advisable to bear in mind the needs of the future and to take notes of suitable material.

The preparation of scientific papers in general is by no means easy, and an immense number of conventions are used in producing books and journals which cannot be observed by instinct. In a book[3] which we have received from Baltimore these are set out with admirable clearness. Brief sections deal with first steps in treating scientific data, plan and order of topics, subject-matter and arrangement, corrections and alterations in proofs and manuscript for printer, and kindred topics, whilst methods of abbreviation, citation, and illustration are satisfactorily described. This is a book which should be useful to the many medical men who have editorial work to do, and its perusal should go far to reduce friction between author, editor, and printer.

## THE NEEDS OF OUR HOSPITALS.

The National Emergency has caused anxiety, and sometimes serious inconvenience in nearly all the hospitals. Their principal needs are personnel, power and provisions, and in places there has been interference with all of these. At the London Hospital, for instance, the initial difficulty was the transport of staff; this was overcome fairly satisfactorily by the use of ambulances and private motors, though some medical and lay workers who were insufficiently labelled were held up and even roughly handled. The next serious trouble was due to the action of the Stepney Borough Council in cutting off the supply of electric current by day so as to prevent its use for industrial purposes. No power was available till the evening, for the X ray plant, Tyrnauer baths, Finsen light, sterilisers and instrument-sharpening plant, the electric lifts were thrown out of action, whilst the difficulties of maintaining efficiency were enhanced by a heavy fog on Wednesday morning. The Chairman of the Hospital, Lord Knutsford, met the Borough Council on Thursday, and this body consented to restore the supply of current, but were unable to give effect to this decision. The out-patient department however, has had to be closed because few patients can attend and because it is difficult to maintain the staff; cases are dealt with in the receiving-room, which has not been overcrowded, and as yet there have been few injuries apart from motor-car accidents. News from other hospitals tells much the same story. At the City of London Hospital, Victoria Park, electric current has been cut off during the day At St. Bartholomew's, there has been some delay in getting patients to and from the hospital, and there as elsewhere private cars could usefully help. Valuable assistance of this kind has been given at St. Thomas's, where there would otherwise have been considerable difficulty in discharging patients to their homes in the country. At this hospital operations which can safely wait are being delayed so as to set free beds for emergency. At Charing Cross Hospital, there has been no abnormal number of casualties and transport difficulties have been removed by the offer of private cars.

On the whole, hospital food supplies are arriving satisfactorily in the London area, with the exception of fish, which is difficult to obtain in adequate quantity. St Thomas's, for instance, is receiving only about half of its normal supply. There is also some shortage of potatoes and green vegetables, especially at the last hospital, and practically every hospital would be grateful for gifts of this kind. Motorists coming to London might well bring with them small quantities of vegetables from their gardens and hand them in at institutions on their route. Milk is reported as sufficient. Difficulty in the maintenance of hospitals is of course inevitable in the early stages of so serious an upheaval, but there is no section of the community which desires to put the slighest inconvenience in the way of hospital administration, and the unfortunate incidents that have occurred are simply the result of misunderstanding. They should give rise, therefore, to no kind of ill-feeling, and their repetition can best be prevented by the plainest possible advertisement of hospital supplies and the fullest explanation of hospital needs to those who are obstructing their fulfilment.

## THE DOCTOR'S RISK IN CERTIFYING.

We stated last week the legal decision which proved fatal to Mr. Harnett's action against Dr. Fisher for alleged negligence in certifying him under the Lunacy Act more than 13 years ago. Another point of law, submitted on behalf of Dr. Fisher but rejected by Mr. Justice Horridge, deserves further discussion, for learned judges do not appear unanimous in their views upon it, and the point is of vital importance to medical practitioners who are concerned with certification under the Act. Mr. Harnett's grievance is his detention in an asylum. The detention was the result of a reception order. The reception order was not the act of Dr. Fisher, but of Colonel Locke, the magistrate who after due examination of the facts signed the order. The reception order is a judicial act; if the magistrate is not wholly and solely responsible some measure of privilege and protection must be conceded to the doctor who merely provides the material which the magistrate examines. If the doctor does not know the limit of his risk he can hardly be expected to take chances with the Lunacy Act. The criminal position is clear. Wilful mis-statement of a material fact is punishable as a misdemeanour (under Section 317 of the Act). What is the legal liability—apart from criminal responsibility for wilful mis-statement—when the doctor acts in perfect good faith?

If statements, possibly defamatory, are made in connexion with the petition there seems no actionable liability for libel. In Hodson *v.* Pare ([1899], 1 Q. B. 455) a man applied under the 1890 Act for the detention of his wife as a lunatic. In answering the question in his particulars as to whether any near relative had been afflicted by insanity, he made the reply: "Yes, her mother, with puerperal fever." The mother brought a libel action, whereupon the husband successfully applied to have the statement of claim struck out as disclosing no cause of action. The Court of Appeal held that the alleged defamatory statements were not actionable. "I have come to the conclusion," said Lord Justice A. L. Smith, "that a justice sitting to administer the lunacy laws, as in this case, is exercising a judicial function and, if that is true, the occasion was absolutely privileged." "The justice," said Chitty, L.J., "has ample power to personally examine the alleged lunatic and to call for the production of further evidence and to hear that evidence on oath. There is thus a statutory judicial proceeding." Lord Justice Chitty's observations hardly need elaborating by reference to the well-known procedure governed by Sections 4–6 of the Lunacy Act. The reception order is, in the words of the statute, "made by the judicial authority"—i.e., the magistrate—who has first to "consider the allegations in the petition and statement of particulars and the evidence of lunacy appearing by the medical certificates and whether it is necessary for him personally to see and examine the alleged lunatic." The judicial authority can, if satisfied, make the order forthwith; if not so satisfied he must appoint an early date for considering the petition and may make such further inquiries as he may think fit. If he takes time to consider the matter the Act gives him the choice of three courses—he may make the order, dismiss the petition, or adjourn the proceedings for further information. When the magistrate has this ample discretion the medical practitioner who furnishes the material upon which that discretion is exercised seems to play a part not unlike that played by a mental specialist who gives evidence in a criminal trial as to the insanity of the accused—evidence which may lead to the detention of the accused during His Majesty's pleasure. In Everett *v.* Griffiths Lord Reading, L.C.J., summed up the position in words afterwards quoted by Lord Finlay in the House of Lords ([1921], A.C. at p. 669). Dr. Anklesaria, said Lord Reading, was consulted in that case "in an advisory capacity. His opinion was expressed to the justice of the peace in good faith, and the justice acted upon it. There is an interposition of the act of the justice which constitutes the detention. It is not the medical certificate, it is the order of the justice, which brings about the detention." Lord Finlay, however, disagreed with Lord Reading, and in Harnett *v.* Fisher Mr. Justice Horridge followed Lord Finlay.

It had been argued for Mr. Harnett that no order could be made by the magistrate without the certificate of the doctor. Where the certificate of the doctor was obtained with a view to obtaining an order the negligent giving of a certificate (and the jury had found that Dr. Fisher was negligent) was a direct cause of the reception order and detention. This argument Mr. Justice Horridge adopted in deciding the point against Dr. Fisher before deciding the further point of law (under the Statute of Limitations) in Dr. Fisher's favour. Lord Finlay had said, in the case already cited, "But for the existence of the certificate the order could not be made at all. And further we cannot leave out of account the effect which that certificate might, and in all probability would, have on the mind of the justice who made the order. Not only is the medical certificate a condition precedent to the making of the order, but it may also have a most important effect in leading the justice to the conclusion that the person is a lunatic." Everett *v.* Griffiths was really decided not on the ground of the immunity of the medical practitioner, but on the ground that there was no evidence of want of reasonable care on his part. Lord Finlay's remarks on causation are, however, important. Lord Reading had said that the medical certificate was a *causa sine quâ non*, but not a *causa causans*. But lawyers take the view that, where there are several links in a chain of causation extending from initial negligence to a subsequent injury, the person guilty of the original negligence will still be the effective cause if he ought reasonably to have anticipated the intervention of the links and to have foreseen that, if they intervened, the result would be that his negligence would lead to mischief. Mr. Justice Horridge thus held that Dr. Fisher, guilty (according to the jury) of the original negligence, ought reasonably to have anticipated that the reception order would follow; therefore the making of the order was not a fresh independent cause, and Dr. Fisher was liable for the consequences of his negligence even though the actual reception order was made by the magistrate.

Mr. Harnett, of course, could obtain no damages from Dr. Fisher unless Dr. Fisher owed him a legal duty to use reasonable care. Such a duty does not always exist. In Thompson *v.* Schmidt (1891, 56, J.P. 212) a doctor's certificate was given under Section 20 of the Lunacy Act; it was not a condition precedent to the *detaining of an alleged lunatic*. The relieving officer requested a certificate before taking the plaintiff to Hoxton Infirmary. The Act did not require a certificate; the doctor was merely employed by the plaintiff's wife to satisfy the mind of the relieving officer before he acted on his own responsibility. Even if the relieving officer would not have acted without the doctor's certificate the certificate, it seems, was not in any legal sense the cause of the relieving officer's act; the doctor had no liability towards the plaintiff. But the circumstances in Thompson *v.* Schmidt were not the same as in Harnett *v.* Fisher. The normal duty of a medical practitioner to use care in signing a certificate was [illegible] in 1862 in Hall *v.* Semple (3 F. & F., 337). Mr. Justice Crompton, trying a case under the lunacy law then in force, told the jury that an action would lie, even in the absence of any spiteful or improper motive or of wilful false statement, if a doctor assumed the duty of certifying without due and proper examination and without making such inquiries as were necessary and such as a medical man ought to make, "not in the exercise of the extremest possible care, but in the exercise of ordinary care." When the authority of Hall *v.* Semple was considered in Everett *v.* Griffiths by the Court of Appeal ([1920], 3 K.B 163) the judges were divided. Lord Justice Atkin thought there was a duty owed by the doctor to the person certified, and that on a breach of that duty the latter could obtain damages. On the other hand, Lord Justice Scrutton thought that "a doctor who voluntarily certifies under the Act of 1890, not at the request of the person examined, but as evidence for the guidance of an independent authority, incurs no liability to the person examined, as there is no legal relation between them." In the House of Lords Lord Cave said he expressed no final opinion upon this point.

Although, therefore, Mr. Justice Horridge had good authority for deciding against Dr. Fisher on the aspects of the case discussed above, there is sufficient judicial uncertainty to make it desirable that the point should some day be settled, beyond all dispute, by the highest legal tribunal. A stay of execution was granted to Mr. Harnett when judgment was recently given against him. If he appeals on the legal point unfavourable to himself it may be possible to get a final decision upon the other legal point on which he succeeded.

## ROYAL SOCIETY OF MEDICINE.

About 50 members attended a meeting of the Section of Surgery on May 5th to hear Dr. W. E. Gye spead on the Origin of Tumours, but Dr. Gye was prevented from attending. It is intended to hold the meetings arranged for the coming week. The society is organising an Emergency Medical Service to work in an area bounded by Park-lane and Edgware-road, Regent-street, Piccadilly and Marylebone-road. Doctors are asked to be in readiness with cars and first-aid necessaries during one hour of the twenty-four. It will be recalled that an emergency surgical aid corps was formed during the war. Part of the society's staff is being housed in its Wimpole-street building, and lodging there for 50 persons has been offered to the Mayor of Marylebone.

# Medical Societies.

## MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

At a meeting of this Society on April 30th a further discussion took place on this subject. Dr. Wilfrid S. Fox, the President, was in the chair.

Dr. A. Lacapère, consulting physician to the St. Lazare Hospital, discussed at length the conditions under which a syphilitic might be authorised to marry. Theoretically marriage should not be allowed until there was absolute proof of non-recurrence, and of inability to contaminate the partner or transmit syphilis to the offspring; but absolute proof of cure could not be established in syphilis, any more than in tuberculosis or other chronic infections. Negative reactions did not furnish an absolute security. Cure was more likely the sooner the treatment was commenced. A series of injections of "914" within a week or two after dangerous contact, followed by clinical and serological observation for a year, should make it possible to permit marriage to take place in the absence of anything abnormal. If there was a primary sore, in spite of a negative Wassermann, still there was hope of obtaining complete sterilisation in a relatively short time, and the treatment, according to the French school, should consist of a series of intravenous injections of "914," followed, after a rest period, by a second series of injections, even a third or fourth, though in these later stages he preferred to use insoluble bismuth preparations. The duration of treatment should be 10 to 12 months, followed by an observation period of 8 to 12 months, after which, if the reaction remained negative, and the result of a provocative injection of "914" was satisfactory, the person might be permitted to marry. In cases in which treatment was started after the appearance of the positive reaction he frequently had recourse to intramuscular injections of "914," or, when these were not well taken, to injections of sulpharsenol, alternating with bismuth. Two, sometimes more, series of treatments were necessary; 18 months was the minimum for treatment; injections of bismuth should be continued for a year after the tests had become negative, and the tests should be negative for 12 or 18 months before marriage was authorised. He also spoke of the treatment of syphilis in the tertiary stage, and said that if the syphilitic had not exhibited any irremediable symptom such as angina pectoris or tabes, the practitioner might concentrate upon securing the disappearance of the actual symptoms, upon getting a negative result in the tests, and upon keeping the patient under observation, making tests at regular intervals and giving an occasional provocative injection. The precautions must be greater in the case of a woman than of a man. If a woman had had syphilis, the results might be seen in abortions or infected children, in spite of negative reactions for a period of years. The woman, therefore, should have treatment during pregnancy, and the children should be watched carefully. He believed that syphilis could not be transmitted to the child by the father if the mother had not first been infected, though the proof of this conjugal contamination was often very difficult to obtain. In the treatment of the expectant mother he found the best results followed arsenobenzol, given by intravenous or intramuscular injection.

Dr. R. C. JEWESBURY contributed a statistical paper analysing the work of the special clinic for congenital syphilitic children which was started six years ago at St. Thomas's Hospital. Two hundred cases of congenital syphilis seen in the clinic involved an investigation of 957 pregnancies of the mothers. The pregnancies in 178 cases had terminated in miscarriages. Of the 779 children born, 81 were shown to be free from syphilis, 274 gave no sign of syphilis, though for various reasons it was not possible to be quite conclusive, 150 were suspected of having syphilis, and congenital syphilis was proved in 270 cases. The history of the father was generally difficult to obtain, and in only 13 cases could the date of his infection be discovered. The longest period of infection previous to the birth of the child was 11 years, and the average period five years. In the case of the mothers the longest period of infection was nine years, and the average three and a half years. Only a small proportion of the women had received adequate treatment. Of the children who came under observation, the largest number were referred for eye trouble, others for rashes, wasting, pains in the limbs, and mental defect. The 200 actual cases of congenital syphilis seen at the clinic were divided into three groups according to age, and it was in the oldest group, from 6 to 14 years of age, that the eye symptoms were most noticeable; also in these the largest proportion of positive Wassermann reactions was obtained. The Wassermann test could not be relied upon in very young children.

Dr. J. H. SEQUEIRA communicated some observations made by his colleague, Dr. Palmer, now obstetrician at King's College Hospital and formerly of the London Hospital, regarding over 2000 primiparæ in the antenatal clinic of the London Hospital and associated lying-in homes in the East End of London. In all these cases a Wassermann test was done, and in only 2 per cent. was there evidence of syphilis. That was a point worthy of consideration, he thought, because current propaganda had rather exaggerated the danger of communication in the early months of marriage, and when one remembered that this mass of material was drawn from an East End population, the lowness of the syphilitic reaction was rather gratifying. It must be admitted that this 2 per cent. did not represent the whole of the infection, because it left out the miscarriages. He thought it quite a common experience for there to be a history of one or perhaps two quite healthy children, followed by a series of miscarriages, or else the subsequent children showed evidence of congenital syphilis. With regard to advice on the matter of marriage, the difficulty arose in the case of a syphilitic who had a positive Wassermann in spite of lengthy treatment and proposed to get married. The duration was important, for time as well as mercury was a factor in the cure of syphilis. Dr. Jewesbury's communication bore out what he had himself so long advocated, the value of antenatal treatment of syphilitic women.

Dr. A. C. PALMER added a few details to the figures given by Dr. Sequeira. The primiparæ numbered 2010, but a positive Wassermann was obtained in only 21.

Mr. WANSEY BAYLY said that both the papers appeared to show that if the parents received adequate treatment there was little danger of the children developing syphilis. There was a tendency to exaggerate the risks of syphilis. In his view there was no reason why marriage should not be permitted provided the patient had received a course of anti-syphilitic treatment before marriage and signified willingness to continue the treatment after marriage. He himself had permitted a number of patients to marry after only one year of treatment—they had continued treatment after marriage of course—and so far such marriages had not produced either syphilitic children or domestic unhappiness.

Dr. HENRY MCCORMAC asked what was to be done in chronic cases which, in spite of treatment, it did not seem possible to get a negative Wassermann. He thought that in the case of a man with syphilis of sufficiently long standing, he was unable to communicate the syphilis to his wife, and if the wife was not infected she would have healthy children; but in the case of a woman with chronic syphilis, although she might not be able to communicate the disease to her husband, she was capable of imparting it to her children.

Dr. LACAPÈRE, in reply, said that the persistence of a positive Wassermann was a dangerous sign of the possibility of general paralysis, and he thought that unless the case was shown to be one of very old-standing chronic syphilis—i.e., up to 12 years—it was unwise to allow a man with a positive Wassermann to marry.

# Medical News.

A complimentary Dinner to Sir St.Clair Thomson President of the Royal Society of Medicine, is to be given by the Section of Laryngology at the Edward VII Rooms, Hotel Victoria, Northumberland-avenue, on Firday, June 4th. Tickets from Mr. Norman Patterson, 82, Portland-place, London, W. 1.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.—The Maudsley Lecture on the Prevention of Insanity, will be delivered at the British Medical Association House, Tavistock-square, W.C. 1, by Prof G. M. Robertson of Edinburgh, on Tuesday, May 18th, at 3 P.M.

On Tuesday afternoon, May 4th, Sir Humphry Rolleston unveiled at the Dreadnough Hospital, Greenwich, a presentation portrait of the late Sir Sydney Russell-Wells, painted by his nephew, Mr. John Wells. In asking the Seamen's Hospital Society to accept the portrait for the staff room of the Hospital, Sir Humphry Rolleston spoke of Russell-Well's great abilities as committee-man and chairman, the clearness conciliation and conviction with which he spoke, his complete mastership of procedure, and his gift of exposition freely utilized for the benefit of the Seamen's Society.

*At the annual conference of the National Council of Public Morals, held last week, Sir Thomas Horder* contributed to the discussion on How to improve the British Race. The *doctors, effort, he said, should* be to arouse in people the recognition of individual duty and service in respect of racial betterment. After stating his case the patient often said: "Now what are *you* going to do about it, doctor?" Whereas the pertinent question should really be: "What do you advise *me* to do about it, doctor?" Health, said Sir Thomas Horder, is always the resultant of the moral control by the individual of the conditions in which he finds himself. Starting off with a capital of health he can by thrifty stewardship add to this, establish it, and contribute to the improvement of the race by handing down an improved constitution to his children. Or, squandering his capital by living upon it, he can pass on a bankrupt inheritance and so increase the elements that make for degeneracy. Clearly, he concluded, the issue lies with the individual.

THE DANGEROUS DRUGS ACTS.—Sir William Willcox addressed a joint meeting of the South-West London Medical Society and the South-West London Chemists Association held on May 5th, on the application of the Dangerous Drugs Acts by the physician and the pharmacist. In view of the great inequality of effect of these Acts on the medical and pharamceutical professions, it would be equitable, he said, for dangerous drugs to be supplied only on medical prescription and not to be dispensed by a medical practitioner except in emergency or in rural districts where a pharmacist was not available. This procedure had been in operation in the case of insured patients, and it worked admirably. It would, he thought, involve no financial sacrifice on the part of the medical practitioner and would relieve him of the troublesome work. The double check, namely, the writing of the prescription by the physician and the dispensing by the pharmacist would afford a double safeguard against error.

WELFARE CENTRES AND BIRTH CONTROL.—In the House of Lords on April 28th, Lord Buckmaster moved "that His Majesty's Government be requested to withdraw *all instruction* given to, or conditions imposed on, welfare committees for the purpose of causing such committees to withhold from married women in their district *information*, when sought by such women, as to the best means of limiting their families" and after a full discussion in which the Marquess of Salisbury, the Archbishop of Canterbury, Lord Balfour of Burleigh and others took part the *motion was agreed to by* 57 votes to 44, the Lord Chancellor stating that they were not expressing any opinion for or against birth control, nor whether propaganda in its favour should or should not be lawful.—The Paddington Borough Council rejected by 21 votes to 20 a *motion by Sir John Ramsay* to give medical officers of welfare centres the same freedom as other medical practitioners in giving advice to patients on methods of birth control.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE ASSOCIATION.—On Tuesday, May 11th, at 4 P.M., Mr. M. S. Mayou will give a demonstration in clinical ophthalmology at the Central London Ophthalmic Hospital, on May 12th at 2.30 P.M., Mr. Stanford Cade will give a demonstration in clinical surgery at the Westminster Hospital. These *are free to* all members of the profession. The courses arranged at the London Lock, Central London Throat. Nose and Ear, Royal Westminster Ophthalmic, and Maudsley Hospitals are cancelled. The course at the Infants Hospital will not be held unless a settlement is reached by May 8th. The course at the Royal Waterloo Hospital may take place. (Information is obtainable from the Secretary of the Fellowship, at 1. Wimpole-street. London, W.1. or Tel: Mayfair 2236.)

The annual congress of the Ophthalmological Society of the United Kingdom was held in London from April 29th to May 1st. Sir John Herbert Parsons presided. A report of this meeting will be published later.

# Births, Marriages, and Deaths.

## BIRTHS.

**ALEXANDER.**—On April 23rd, at Overstrand Mansions, Battersea, the wife of Captain R. H. Alexander, M.C., R.A.M.C., of a son.

**GRIFFITHS.**—On April 22nd, at 90 Harley-street, the wife of H. E. Griffiths, M.S., F.R.C.S., of a daughter.

**MATHIAS.**—On April 18th, at Tenby, the wife of Hugh Mathias, F.R.C.S., of a son.

**NORMAN.**—On Apirl 25th, at Chatham, the wife of Col. H. H. Norman, C.B.E., R.A.M.C ,of a daughter.

**RICHMOND.**—On April 20th, at the Lawn, W., the wife of Dr. D. S. Richmond, of a daughter.

**TOOGOOD.**—On April 25th, at Goden Bank, Liskeard, Cornwall, the wife of Sherman Toogood, M.A., *M.R.C.S., of a daughter.*

## MARRIAGES.

**EATONPEARD.**—On April 29th, at Emmanuel Church, West End, Dr. Douglas Eaton to Hiliary, daughter of the later Lieut.-Colonel Peard, C.M.G., R.A.M.C.

***ELKINGTON — RICHARDSON-BUNBURY.*** — *On* April 29th, at Blatchington Church, Guye Waterman Elkington, M.B., M.R.C.P, to Kathleen, only daughter of the late Mr. Moutray Richardson-Bunbury, of Seaford.

**HUTCHINSON—WALLEY.**—On Apirl *30th*, at St. Matthew's, Oakley-square, N.W. Donald H. A. Hutchinson, M.D., to Constance E. Walley, Edin.

**RHODES—MOLYNEUX.**—*On* April 28th, at St. Mary's, Allithwaite, Richard L. Rhodes, M.A., B.Ch., to Kathleen Margaret, youngest daughter *of* Mr. *and* Mrs. A. J. Molyneux, of Allithwaite Lodge, Grange-over-sands.

**SLOT—*COHEN*.**—On *Arpil 27th*, at the West London Synagogue, Gerald Maurice Slot, M.D., M.R.C.P., to Evelyn Irene, younger daughter of Mr. *and the* late Mrs. P. Cohen, of 42, Aberdare Gardens, Hampstead.

**SHERVILL—MOFFATT.**—On April 28th, at St. Merryn, Cornwall, Edgar Arthur Shervill, M.R.C.S., to Jane Elizabeth Forbes (Jean), only *daughter of the* late Thomas Forbes Moffatt and Mrs. Moffatt, of Trescore, St. Merryn.

## DEATHS.

**BURNS—GEMMEL.**—On *April 28th*, suddenly, at his residence, 114, Princes-road, Liverpool, Dr. Archibald Burns Gemmel, C.B.E., *retired* Brebet-Colonel R.A.M.C. (T), sometime commanding First Western General Hospital Fakazerley.

**DUTCH.**—On April 30th, after a long illness, at his residence, 8, Berkely-street. London, W. 1, Major Dutch, M.D., T.D., aged 64, who devised a number of ingenious medical instruments.

**FREDERICK.**—On April 28th, at 1, Cambridge-road, Seven Kings, Edward Gurdon Frederick, M.R.C.S, L.R.C.P., aged 54.

***FRANCE.***—On April 30th, *at a nursing* home in London, Frederick Ernest (Eric) *France*, N.B., B.S.Durh, late Capt, R.A.M.C. (T) in his 59th, year, sometime member of the Medical Resurvey Board, Ministry of Pensions.

**JOYNT.**—*On April 27th*, at 12, Eliot-place. Blackheath, of uræmia, Edward Hearne Joynt, retired Liuet.-Colonel, R.A.M.C.

**NANKIVELL.**—On May 1st, very suddenly, at Bude, Frank Nankivell, M.D., of Port Isaac, aged 74.

**Rivers.**—On April 23rd, at Worsboro Bridge. Barnsley, Walter Courtenay Rivers. M.R.C.S., D.P.H., a keen student of *Tuberculosis* and Sociology.

## ÆQUANIMITAS MEDICA.

No quality in the physician or surgeon, said William Osler in a famous address, takes higher rank than imperturbability and the general strike gave the medical profession ample scope for the exercise of this essential virtue. Below is set out the spirit in which the official medical department of London carried out its varied duties, and all the evidence which has reached us goes to show that the same spirit ruled in every part of the country and in every kind of medical practice. What has been happening will only have its effect in the distant future, for the physical forces which deteriorate the health of the nation do not produce their result at once, but have their repercussion long afterwards. For this reason, if for no other, medical officers were wise not to abandon their routine duties for other spheres which appeared more attractive or fruitful at the moment. The temporary upset in the hospital services showed signs of amelioration even before the situation was relieved. Provision was made in many places for such emergencies as could be foreseen; apart from these, there has probably never been a time when the carrying on of medical practice in its every detail of daily routine was of more importance to the national weal. Practitioners do well to cultivate—to recall another phrase of Osler's—such a judicious measure of obtuseness as enabled them to meet the exigencies of practice with firmness and courage.

Sound organisation and generous assistance from the public enabled the metropolitan general hospitals to accommodate themselves rapidly to the conditions which followed the sudden dislocation of many public services. The difficulties which faced them at first were surmounted and generally speaking their work went on almost as usual. The mechanism of a large general hospital is widespread and complex; the smooth inter-working of many departments is needed to secure efficiency, and so many people—staff and patients—have to enter and leave each ward every day that any serious interruption of communication might easily have had serious results. In many hospitals preliminary arrangements were made in case of the emergency arising, for although the Government was able to guarantee the free movement of food-supplies, there were other essential services to be arranged: the conveyance of in-patients to and from their homes, the regular arrival of the lay and medical staffs, the replenishment of stores other than food, the maintenance of light and heat. In these and other matters involving internal organisation almost complete success was attained. During the first two or three days there was a little scarcity of fish and fresh vegetables, but the supply of all kinds of food became ample and regular, and there was at no time any real difficulty about milk. Obstacles to the movement of personnel, which at first looked serious, were quickly removed by owners of motor cars who placed an immense fleet of vehicles of all descriptions at the disposal of the hospitals. Regular services were organised for bringing in the staff and returning them to their homes, for the conveyance of doctors who had no cars of their own, and for the use of patients, some of whom had to be carried considerable distances. Here and there some members of the staff slept on the premises. The out-patient departments were necessarily chiefly affected, as out-patients are drawn from all parts of London and the suburbs, and transport difficulties at first reduced the attendance to a minimum. An increase in the number of trains and omnibuses, however, rapidly removed this disability, and on Monday last a larger number of out-patients attended at St. Bartholomew's Hospital than during the whole of the previous week. In the medical schools of the teaching hospitals systematic lectures were given, although practical courses were largely suspended owing to the fact that most of the students in a position to do so enrolled themselves as special constables or volunteers in essential services. For a time one hospital or another laboured under serious difficulties because light and fire were not available, but last Saturday supplies were partially restored, and on Monday they were extended to out-patient departments. The best commentary on the rumours of disturbances in the East End is afforded by the fact that there was no unusual pressure upon the Poplar Hospital for Accidents.

Turning to the public medical services in London, we understand that the work of the medical department of the London County Council was carried on without any dislocation whatever. The initial difficulty of transport was met partly by voluntary provision of private cars, partly by willing acquiescence of the staff in covering the ground on bicycles or on foot. Of the 00 doctors engaged in medical inspection, of the 300 or more school nurses, and of the 03 care committee organisers none failed to report for duty, although in individual cases the work was not done without some sacrifice of sleep, physical exhaustion, and even blistered feet. The voluntary attendance of children at cleansing stations did not appreciably drop off even after this measure ceased to be compulsory in certain areas. Notification of infectious disease among school children was made in envelopes prepaid at full postal rate to avoid delay in this essential kind of information. Swabs and culture tubes for the diagnosis of diphtheria were circulated by the private cars of the medical staff. The work of the chemical branch was unimpaired except in so far as milk samples for the present were not accepted by parcel post. Work in connexion with midwives, the Children's Act and tuberculosis went on as usual, the difficulty in taking patients to sanatoria being met by the offer of Red Cross ambulances for the purpose. The health of London during the emergency gave no cause for anxiety. There was little or no increase required in the supply of free meals for necessitous children, and the continuous efforts of the medical, dental and nursing staff maintained a full service of inspection and care. It would not be vainglorious to claim that a large measure of equanimity was achieved.

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

## CLXXII.—TREATMENT OF DIABETES.

### II. INSULIN TREATMENT.*

THE ideals set out in the article on dietetic treatment cannot be achieved in every case but should always be aimed at. Insulin does not cure diabetes, but it can restore a comatose patient to life and will make most patients feel quite well. It is not necessary for every patient. If a patient is over 50 years and can take a diet containing 50 g. of carbohydrate, and enough protein and fat to make up an adequate caloric value, insulin is not essential, though a small dose (5 units) will make the patient feel better. To children or young adults small doses of insulin should certainly be given, as it is essential to keep the patient in the best possible health with the least possible strain on the beta cells of the islands of Langerhans. If the carbohydrate cannot be raised to 40–50 g. without causing glycosuria or a raised fasting value of the blood-sugar, insulin is necessary. The popular belief, "once insulin, always insulin," is true in the sense that if a patient has been restored from coma and still needs 50 to 100 units a day he will probably die if the insulin is not given. But in mild cases it can always be stopped, provided that the carbohydrate is simultaneously reduced. When this alternative is offered the patient often prefers to continue the insulin. Except in emergencies, an attempt should first be made to control the condition by means of diet, since the discovery of the correct dose of insulin is thus made easier. Estimation of blood-sugar is not essential, but greatly shortens the time taken in balancing insulin and carbohydrate. The urine passed during the day should be collected three-hourly and as many specimens of night urine as possible without disturbing the patient. Benedict's solution should be used for sugar tests and the results charted. If the urine still contains sugar, or the blood-sugar is still too high, in spite of careful dietetic treatment, the following régime should be adopted.

#### *Standard Régime.*

A small dose of insulin, 5 units, should be given before breakfast and the urine of each three-hourly period tested for sugar. If the urine contains sugar before breakfast, the blood-sugar is probably above 0·20 per cent. and the urine in the period 0–3 hours after the insulin is certain to contain sugar. If the dose of insulin is sufficient to lower the blood-sugar below the threshold of the kidney for sugar (0·18 per cent., as a rule), no sugar will be present in the period 3–6 hours after insulin. If sugar reappears in the 6–9 period it means that the blood-sugar is again above 0·18 per cent. In this case the same dose should be persevered with for three days to see if the urine in the 6–9 and subsequent periods will become sugar-free. If this does not occur the dose of insulin must be increased to 10 units, and the same procedure adopted. If, however, the urine in the 3–6 period still contains sugar after a further three days' treatment, the insulin should be increased to 15 units and the effect watched. If this fails to render the urine sugar-free in the 3–6 period, an evening dose of 5 units should be given. This dose can be increased by 5 units every three days up to 15 units. If the urine still contains sugar in the 3–6 period, it is well to have an estimation of the blood-sugar made if possible. If the condition is still resistant, the dose can be increased by 5 units in the morning—i.e., 20 units—followed by 5 more units at night every three days until the urine does become sugar-free.

In practice it is rare for the condition to be so resistant unless the patient has another disease present which is making the diabetic condition much worse—e.g., gangrene of the leg. When an adequate dose of insulin is given and the urine is sugar-free throughout the day, it is advisable to have an estimation of the blood-sugar made before the insulin is given, so as to know whether the blood-sugar is below 0·13 per cent. or is only just below the threshold—0·18 per cent. If it is not possible to make estimations of the blood-sugar, some idea may be obtained by collecting the urine every hour after the usual time for the insulin injection, but omitting the insulin. If glycosuria occurs in any of the first two specimens the blood-sugar was probably above 0·13 per cent., provided always that the threshold of the kidney is set at the normal level. When the blood-sugar has been reduced to normal the diet can be cautiously increased, adding carbohydrate as fruit or milk in proportion of 1 unit of insulin to 2 g. of sugar. It is unwise to increase carbohydrate above 50 g. in a severe diabetic, and this amount is just sufficient to provide enough variety to make the diet palatable. The urine passed just before the insulin is given should be tested for sugar.

#### *Hypoglycæmia.*

As the patient improves, there may be symptoms of hypoglycæmia. The mildest are sweating, hunger pains, pallor, a feeling of limpness, dizziness, and tremor of the hands. Rather more severe ones are numbness of the hands or face and diplopia. The serious signs are (1) a state of coma resembling a deep sleep from which the patient cannot be roused; (2) a fit, rather like an epileptic fit, to which children are liable; (3) delirium.

For the mild attacks it is sufficient to take some of the food which would be eaten at the next meal, or some orange juice, or two lumps of cane sugar. If this does not relieve the symptoms more sugar should be eaten.

For the severe attacks, when a patient is unable to swallow, an injection of 15 minims of 1 in 1000 adrenalin or 1 c.cm. of pituitary extract will restore the patient to consciousness within five to ten minutes as a rule. When he recovers he should be given six lumps of cane sugar. If the adrenalin fails to restore consciousness in 30 minutes, it is advisable to give 200 c.cm. of a 5 per cent. solution of dextrose per rectum, or intravenously if the patient does not improve.

The patient should be able to recognise these symptoms, and the dose of insulin should be reduced by two or more units according to the severity of the reaction. A common cause of overdose is the taking of unwonted muscular exercise which burns up some sugar. This can be allowed for by taking less insulin or more carbohydrate. The patient's relations should know how to treat an overdose, and sterules of adrenalin should be at hand. The patient should always have sugar in his pocket or in a bag hung round the neck; he should carry a notice stating his condition and asking that adrenalin should be injected and sugar given if he becomes unconscious. This is a necessary precaution, since once the patient has become unconscious diagnosis is difficult.

#### *Reasons for Increasing Dosage.*

The dose of insulin must be increased greatly (1) if the patient develops another infection, (2) if diabetic coma ensues. Any infection is likely to cause some hyperglycæmia, or even glycosuria, and permanent decrease in sugar tolerance may ensue unless insulin is given in adequate amounts. The dose of insulin should be increased by either 2 or 4 units for mild diseases, such as colds in the head, small pimples or boils, even though no sugar has appeared in the urine. When a mild infection is over the dose may be reduced; after a severe infection it is advisable to wait for the first signs of an overdose. If the infection has been severe enough to cause glycosuria it may be necessary to give large doses of insulin. If possible, estimations of the blood-sugar should be made, but if this cannot be done the dose of insulin must be gauged by the presence or absence of glycosuria.

The urine should be collected, as far as is possible, in three-hourly periods and tested for sugar. Suppose that a patient, who has been taking 15 units in the morning and 10 in the evening, is taken ill during the night—e.g., with "influenza"—and the urine passed at 8 A.M. contains sugar, whereas it is usually sugar-free, in this case the usual dose of 15 units would be too small, and at least 20 units should be given. *The urine in the period 0–3 hours is certain to contain* sugar, but if the dose of insulin has been adequate there will be no glycosuria in the 3–6 period In this event the urine must be tested every three hours, and as soon as glycosuria occurs 10 units should be given. If, however, the urine for the 3–6 period contained sugar, the dose of insulin was inadequate and another 20 units should be given. If the urine for the next 3–6 period also contains sugar, the insulin should be increased to 25 units and its effect watched in the same way.

---

* Part I., on the Dietetic Treatment of Diabetes, was published in THE LANCET of May 1st.

If this procedure is followed it is safe to give large doses of insulin every six hours without any real risk *of causing an overdose It is sometimes necessary* to give over 100 units, and even 200 units in the 24 hours. The night urine should be collected as far *as is possible* without awakening the patient specially, and if the condition is a grave one the insulin should be given six-hourly at night. When the urine for any 3–6 period is free from sugar, no insulin should be given until sugar reappears, and then the dose should be reduced by 5 or 10 units. During the convalescence there is some risk of an overdose, and it is a great advantage to know how the blood-sugar is behaving

### *Coma.*

As soon as the diagnosis is made (and after the blood has been collected for a blood-sugar determination), a large dose of insulin—50 units—should be injected. To avoid a possible overdose give 2 *oz. of* dextrose by *mouth or* by a stomach or *nasal* tube if the patient cannot swallow.

Collect urine by catheter three-hourly and test for sugar If the urine in the 3–6 period contains sugar, a further 25 units should be given. If the patient shows no signs of recovery, another 50 g of dextrose should be given together *with 50* units of insulin. A further dose of insulin should be given six hourly after testing the urine of the 3–6 period No insulin should be given if the urine of the 3–6 period is sugar-free *unless sugar is given at the same time*; there is then little danger of overdose As soon as sugar reappears in the urine insulin should be given again, the dose being reduced by 5 to 10 units.

*Other* measures should not be neglected; ol. ric., ℥ii., should be given with the first dose of sugar, and 10 oz. of water should be administered by a stomach-tube half hourly for three hours and then every hour. When the patient regains consciousness, the ordinary diabetic diet with 1 pint of milk added should be given, together with an adequate dose of insulin. A careful search should be made for the cause of the coma which is usually an infection of some sort. Any septic focus should be dealt with promptly.

### *Necessary Operations.*

Except in emergency operations, a preliminary course of treatment is advisable in order to discover *how* much food and insulin are required to lower the blood-sugar to normal. If possible local or spinal anæsthesia should be used as these interfere least with the sugar metabolism; the combination with them of gas and oxygen causes little disturbance so long as asphyxia is absent. If ether or chloroform has to be given, remember that ether causes a rise in the blood-sugar and inactivates insulin; chloroform causes no such rise but may damage the liver. In any case give 2 oz. of dextrose two hours before the operation together with 30 units of insulin. After the operation give food suitable to the ordinary patient, injecting a sufficient quantity of insulin The urine should be collected in three-hourly periods and the dose gauged accordingly. One pint of milk containing 21 g. of lactose requires 12 units. Any operation may lead to diminution in sugar tolerance, and so should be avoided unless a definite source of sepsis or a malignant growth is present.

GEORGE GRAHAM, M.D., F.R.C.P. Lond.,
Assistant Physician, St Bartholomew's Hospital

# Medical Societies.

## ROYAL SOCIETY OF MEDICINE.

### SECTION OF MEDICINE.

A MEETING of this Section took place on April 27th under the presidency of Dr. HUGH THURSFIELD, when Dr. E P. POULTON opened a discussion on the

### *Clinical Significance of the Respiratory Metabolic Rate.*

Discussion, he said, would probably be limited chiefly to the basal metabolic rate, in other words, the absorption of oxygen and the output of $CO_2$, as measured in the morning before breakfast—i e., about 12 hours after a light meal taken on the previous evening. It was desired, however, that in the discussion comments would extend over a wider field and that results would be produced after the taking of food and after exercise. Most of this work in recent years had been done in connexion with exophthalmic goitre, a subject which was very fully discussed by the Society not long ago.

*Technique.*—The measure of the direct heat produced was not used as a clinical method. The means of indirect calorimetry were divisible into the open circuit method and the closed circuit method. In the first of these, air from the atmosphere was breathed through a mask and valves, and the expired air was collected. The Douglas bag was usually employed in this country, and the method was shortened by substituting a spirometer for the bag, as the air was then measured during its collection. The calculation of the absorbed oxygen was complicated by the alteration in volume undergone by the inspired air during the act of breathing. The open circuit method had been used only for the determination of the carbon dioxide It would be generally admitted, he thought, that to measure either oxygen alone or $CO_2$ alone was a second best method, as the double determination gave a valuable check on the results, and the respiratory quotient could also be calculated. The closed circuit method was the more favoured, the oxygen alone being determined. A spirometer was filled with pure oxygen and the $CO_2$ was absorbed in the circuit, the rate of fall in the spirometer indicating the volume of oxygen absorbed.

*A New Apparatus.*—Dr. Poulton and Dr. Campbell had together devised a new type of apparatus, which was on view and was demonstrated at the meeting. With this apparatus it was claimed: (1) *that the* results for oxygen and $CO_2$ were *obtained during the* actual investigation, so that one could be certain from one five minutes to another how constant the metabolism was; (2) the *patient breathed* ordinary air, thus dispensing with any preliminary saturation of the tissues with pure oxygen; (3) the experiment could be prolonged *indefinitely if the* source of the oxygen was pure; (4) if required, a volumetric tracing of the respiration could be obtained.

*Normal Standards*—There were, he said, two standards in general use to obtain the normal figures for any individual. One was by calculating the normal metabolism from the body surface which was obtained from the person's weight and height from the Du Bois diagram. The other was by Dreyer's formula, in which only the body-weight appeared. It seemed to be the custom to take the body-weight at the time of the experiment, even though the patient *might* be either over-fat or wasted by disease. In the latter case the metabolism was lower than it would be if it had been calculated when the *patient* was of *normal weight* before the disease began. Dr. Poulton considered this was wrong, as the patient should be regarded as a physiological unit. Still, in the case *of the wasted* patient it might be defended, as the wasting had diminished his protoplasm and so *diminished* the metabolism. The weight of the *individual when* he was healthy, or the predicted weight, should always be used in calculating the metabolism. The chest measurement was of little value when the patient was either much wasted or over-fat; therefore it was necessary to fall back on his body length in order to determine what his weight should be; and it would be of value to have also such factors as the length of arms and legs.

*Clinical Significance.*—Practically all our fundamental knowledge on the variations in basal metabolism, said Dr. Poulton, was due to the work of Magnus Levy in connexion with thyroid disease. Its clinical significance in that disease could be regarded from two points of view—the diagnostic and the indications as to the effect of treatment. It was well known that in hyperthyroidism the basal metabolism was raised; on the other hand, it was lowered in cretinism, myxœdema, and the post-operative disease. It must not be forgotten, however, that such conditions as fever and leukæmia caused a raised metabolism, while starvation, under-feeding, and Addison's disease produced a lowered metabolism. Certain patients, though giving well-marked signs of Graves's disease, showed a normal metabolism, Means's name for these being "border-line" cases. Dr. Poulton considered that the basal metabolism was of great value as a guide to treatment—i.e., both in cases of exophthalmic goitre and as a guide to the right dosage of thyroid in cretinism and myxœdema.

*Obesity.*—He thought it likely that in the future respiratory tests would be more frequently used than at present in the treatment of conditions of obesity. Means found that the basal metabolism per unit of body surface was about normal in obese people, but this raised the question of what was the correct standard of comparison in such cases. If the metabolism of the healthy subject before he became fat was taken as the standard, then the basal metabolism in obesity was usually high, a peculiar fact seeing that adipose tissue by itself probably had a very low respiratory exchange, and the fatty tissue surrounding the patient also tended to prevent the loss of heat, despite some increase in the body surface. An increased metabolism of this kind might be due to increased food ingestion, on the analogy that fasting caused a lowered metabolism, hence over-eating and under-exercising might be regarded as the main cause, rather than some endocrine disturbance. Some observations by Plant seemed to show that it was not so much the basal metabolism which was at fault as the specific dynamic action after the intake of food, seeing that after a protein meal had been eaten the rise in the respiratory exchange was less than normal. Dr. Campbell and the speaker had conducted some observations on the effect on the respiratory exchange of a sufferer from severe bronchitis and asthma. They found that the respiratory quotient as the result of exercise was lower than among normals, the total oxygen intake remaining the same. Treatment with oxygen caused a rise in the quotient to about the normal. Hetzel and Long found low quotients for exercise in diabetic patients.

### *Discussion.*

Dr. C. M. **Wilson** spoke of the precautions which were necessary in order to secure actual measurements of the metabolic rate, and said the discussion would be of value in so far as it showed these measurements to supply something which clinical methods failed to show. There were two groups in which these measurements showed hyperthyroidism, and one in which they showed hypothyroidism. In the first of these one must place the nervous woman who had palpitation and perhaps loss of weight. A proportion of them were due to hyperthyroidism and would respond to suitable treatment; in other words, the diagnosis could be made in this way at a time when it would be impossible by clinical methods. Treatment commenced at this stage might be very effective, but started later on might prove difficult. Also there were cases in which it was very important to decide whether the condition was a non-toxic goitre in a nervous woman, or a toxic goitre producing nervous symptoms. The second group of hyperthyroidism in which the measurements were of value were cases of women whose outstanding symptom was menorrhagia, yet without abnormal pelvic signs. A proportion of these cases responded to X ray treatment of the thyroid gland. If the basal metabolic rate was normal, not only would the X ray treatment not be effective in stopping the menorrhagia, but it was not justifiable to apply the rays to an over-active thyroid. With regard to hypothyroidism, these metabolic measurements were not required for a frank case of myxœdema, but there was a class of case which stopped short of myxœdema and yet had a definitely lowered basal metabolic rate and which cleared up on the administration of thyroid. These measurements of metabolism did not indicate when surgery should be used and when X rays should be applied, but they enabled whatever treatment was chosen to be conducted with safety. If rays were being applied the measurements indicated when they should be stopped, and prevented the operator suspending them too soon. To operate surgically when the basal metabolic rate was rising was to ask for trouble.

Dr. H. **Gardiner-Hill** communicated a few general results arrived at by examining 4000 cases in the last five years. Determinations of the basal metabolic rate were of considerable value when the thyroid condition dominated the clinical picture. In pituitary obesity there seemed to be no definite alteration in the basal metabolic rate. In six cases of acromegaly the rate was within normal limits in two, slightly raised in two, unaltered in two. It tended to be below normal in fat children. Some cases of adrenal disturbance had also been investigated, but the metabolism was not altered. In cases of amenorrhœa in which there were no endocrine stigmata the rate was within +15 and −15 per cent. Two male castrates gave normal results, but of 12 female castrates 5 gave −60 to −35 per cent. and had definite symptoms of myxœdema. All the five had had double ovariotomy performed because of flooding. In the diagnosis of early or latent cases of myxœdema considerable help had been afforded by the estimations of the metabolic rate, particularly in differentiating them from other forms of œdema. He and his colleagues had seen 20 cases of sterility and repeated miscarriages in which the gynæcologist found no local cause, and in 10 of these there was a low metabolic rate. Pregnancy had been known to have taken place since in seven of them and the labour pursued the normal course to full term following the administration of desiccated thyroid.

Dr. R. D. **Lawrence** said he was not so optimistic as Dr. Wilson as to the value of these estimations in giving more information than did clinical investigation. During the last year he had made a practice of guessing what the figures would be, and in the vast majority of cases his guess was within 5 per cent. of the truth, except when the figures were very high. He personally found that the pulse, loss of weight, tremor, nervousness, and excitability gave sufficient indications. In minor classes of hyperthyrodism, when one could not be sure whether a neurotic element underlay the condition, he did not find the metabolic rate was of any value. In nearly all cases of Graves's disease the respiratory quotient was lowered; it might be 0·71, 0·73, and often it was below 0·75. It rose coincidently with the improvement in the case. When the respiratory quotient was very low he viewed the case gravely and considered it was not operable for the time being. The total metabolism, as measured in calories, went up markedly in Graves's disease, but not in diabetes proper. The fasting blood-sugar was most important; in diabetes this was raised, but in Graves's disease its level was not altered; it was always normal. This seemed to depend on the glycogen stores of the body.

Dr. **Reginald Hilton** pointed out how difficult it was to avoid errors in these investigations. It was necessary to know what was the respiratory quotient, as it bore an inverse relationship to the metabolic rate. The loss of weight occuring in cases in which artificial pneumothorax was induced presented a clinical problem. He was inclined to agree with Dr. Lawrence that computation of the metabolic rate was rarely necessary, and it was better to do without estimations than that they should be poorly done.

Dr. POULTON, in a brief reply, said the discussion showed how varied were the uses to which this estimation was being put in London, and some valuable data were being accumulated He agreed that in the bad cases there was a lowered respiratory quotient.

## CAMBRIDGE MEDICAL WORTHIES.

Sir StClair Thomson, the President, described the social evening of the Royal Society of Medicine on May 3rd as a respite from the serious affairs of the hour. There was a large gathering of Fellows and their guests, and Sir Humphry Rolleston's address on Some Worthies of the Cambridge Medical School was enjoyed all the more because of its irrelevance to the political situation. The selection of individuals for special mention, he said, had been no easy task; the Cambridge medical graduates' club had 600 or 700 members, all of whom were doubtless worthy, and amongst the 80 presidents of the Royal College of Physicians of London since 1518 there had been 37 who held Cambridge degrees Of these John Caius was *certainly one of the greatest benefactors to his* University (which was founded, so he had solemnly contended, 390 years before the birth of Christ) The originator of scientific anatomy and physician to three sovereigns, Caius was responsible for the second *foundation of Gonville College in the interests of* medicine; but it was unfortunate that he consented to become its master, for he was out of sympathy with the militant protestantism of his time His rooms were raided, the "Popish trumpery" therein was thrown out of the *windows, and Caius himself was* expelled from the University. Gonville and Caius College, said Sir Humphry Rolleston, had provided seven of the 18 Regius professors in the University. Amongst these was Francis Glisson, who anticipated modern muscular physiology by a century and whose observations on rickets, which finally appeared in the famous "Tractatus de Rachitide," almost certainly inspired the work of Whistler, published at Leyden. Following him the Cambridge school produced a long series of interesting and distinguished men—William Heberden the elder, the friend and medical attendant of Samuel Johnson, by whom he was described as "the last of the learned physicians"; Robert Glynn, who was born in Cornwall and educated at Eton and who would never charge fees to Etonians or Cornishmen; Sir Busick Harwood, the witty and licentious professor of anatomy who made successful experiments in blood transfusion, offered his guests at dinner the turbot dissected for his students, and sent Sir Isaac Pennington, the Regius professor, a challenge to a duel. It was of Pennington was written:—

> "When *Pennington for female ills indites,*
> Studying alone, not what, but how he writes,
> The ladies, as his graceful form they scan,
> Cry, with ill-omened rapture, Killing man."

The challenge, however, was ignored, and Sir Isaac lived to the age of 72 and *died a bachelor,* which enabled him, Sir Humphry Rolleston said, to make generous benefactions to his College. Pennington's successor was John Haviland. He found the medical school in a precarious state and under threat of abolition. As a remedy he introduced *regular courses* in pathology and the practice of medicine and made examinations a really serious test of what the candidate knew. He wrote little or nothing, "but if," said Sir Humphry Rolleston, "the medical school is his memorial he could hardly wish for a better." *After referring* to Sir Thomas Watson, whose lectures enjoyed wonderfully long life as a text-book, Henry Thompson, described as a most cautious *physician* and said to have once prescribed half a leech, and Henry Hales Bond, who succeeded Haviland as Regius professor and held the office for 21 years, Sir Humphry Rolleston spoke of the renascence of the medical school which occurred during the middle years of last century and was associated especially with the names of Sir George Edward Paget, Sir George Murray Humphry, and Sir Michael Foster. Paget, he said, was the most distinguished Regius professor at Cambridge since Glisson He was a quiet and very able man and was responsible for the institution of the natural sciences tripos and bedside examinations for the M.B.; the D.P.H. was also started in his 20 years' term of office. Humphry was appointed surgeon to Addenbrooke's Hospital at 22, *when he* had never even amputated a finger; he was a great anatomist and an arresting and impressive teacher; he found the medical school insignificant and was largely instrumental in making it what it is. Foster laid the foundations of *Cambridge physiology. After* a brief account of the extraordinary career of Humphry's successor, Alexander Macalister, who qualified in medicine at 17 and was professor of anatomy from 1883 till his death in 1919, Sir Humphry Rolleston concluded his *address by speaking of some* of the less familiar aspects of the life of the late Sir Clifford Allbutt. Amongst his hearers there were many *who had* not known that Sir Clifford Allbutt had intended to devote himself to art and that he was the original for the Dr Lydgate of George Eliot's "Middlemarch," but all of them joined with his successor in remembering respectfully the contributions of this great man to his university and to science.

At the end of the address there was an opportunity for conversation and to look at the interesting exhibits arranged in the library, many of them lent from the Wellcome Museum by courtesy of the curator. The society's practice of holding social evenings again justified itself to the full.

## Parliamentary Intelligence.

The *Midwives and Maternity Homes Bill,* which has already passed through the House of Commons, was read a first time in the House of Lords on April 28th.

*Mercantile Marine.*—In reply to a question by Mr. Beckett, Sir P. Cunliffe-Lister stated that the classification of the causes of death *of persons employed* on British merchant vessels had been referred by the Board of Trade to the Permanent Consultative Committee on *Official Statistics. The Board antici*pate that the report of that Committee *will be ready* shortly.

*Education of Defective Children.*—In reply to a question addressed by Mr. Robert Morrison to the President of the *Board of Education* asking whether, in view of the fact that since the issue of Circular 1310, 169 local authorities had submitted proposals *for* making further provision for defective children, he would state how many of these proposals had been deleted in the revised *programmes.* Lord E. Percy replied that such proposals had been postponed in a few cases but he had not asked any authorities to *delete them* from their programmes.

*Lunacy Law.*—Mr. Pethick-Lawrence asked the Minister of Health *whether his* attention had been called to the *remarks of a* High Court Judge on April 27th in giving judgment on a recent case, in which he pointed out the hardship created by the existing state of the law, and expressed regret at the decision he was thereby compelled to reach; *and whether he con*templated the introduction of legislation to secure that in future a sane man detained in an asylum *should not be effectively* prevented from bringing an action until it was too late to succeed. Mr. Chamberlain replied that he did not at present contemplate fresh legislation but the points were receiving consideration.

## A FAKIR DEMONSTRATION TO DOCTORS.

A demonstration, said to be in the interests of science and for the benefit of the medical profession, was given by Fakir Dr. Tahra Bey a few days ago at the New Scala Theatre. The place was well filled with invited guests; a panel of 40 medical men had seats reserved on the platform, and a few volunteers from the audience joined this jury. An interpreter stated that Tahra Bey had graduated in medicine at Constantinople and that his sole object was to demonstrate to scientists the influence of mind over body. The fakir, who was clad in oriental costume, then gave an exhibition of his power to enter a state in which considerable physical insult can be suffered without pain. After some manipulation of his neck he fell rigid; he was placed on his back, supported only by two blunt scythe blades several feet apart; a block of stone weighing at least 60 lbs., was lifted on to his abdomen and chest, and a heavy sledge hammer was brought down forcibly on the stone by an assistant. The state of so-called cataleptic rigidity thus demonstrated was followed by a period of analgesia during which the fakir, chatting pleasantly in French the while, pierced his cheeks with hat pins, worried his neck with a large knife which passed through a fold of skin, and allowed a surgeon to transfix any part of his flesh with a sharp instrument, the forearm being the site chosen. These operations were practically bloodless. He also lay down on a bed of vertical nails while an assistant stood on his body. There followed a demonstration of thought reading, which was difficult to follow accurately, but which apparently satisfied those members of the audience who personally tested the fakir's powers. Finally, he endured burial for ten minutes in a coffin which was covered with sand, his mouth and nose being lightly plugged with cotton-wool but his hands left free. When he emerged it was stated by an assistant that his pulse rate was 80. At his first appearance, the pulse rate was ascertained to be 118 and the fakir said that it was normally 120.

The explanation given of the means whereby Tahra Bey gained control over his circulatory, nervous and respiratory systems was unintelligible, and the replies to certain pertinent questions were barely coherent. We have received from many sources alternative explanations and suggestions for tests under experimental conditions.

◆

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEKS ENDED APRIL 24th AND MAY 1st.

*Notifications.*—The following cases were notified during the week ended April 24th: Small-pox, 130 (last week 213); scarlet fever, 1502; diphtheria, 866; enteric fever, 42; pneumonia, 1301; puerperal fever, 60; cerebro-spinal fever, 10; acute poliomyelitis, 5; encephalitis lethargica, 52; dysentery, 6; ophthalmia neonatorum, 107. There were no cases of cholera, plague or typhus fever notified during the week.

*Deaths.*—In the aggregate of great towns, including London, there was 1 (1) death from enteric fever, none from small-pox, 81 (35) from measles, 6 (1) from scarlet fever 57 (7) from whooping-cough, 38 (13) from diphtheria, 51 (17) from diarrhœa and enteritis under 2 years of age, and 209 (35) from influenza. The figures in parentheses are these for London itself. The notified deaths from influenza for the 105 great towns show a diminution of well nigh 100 on the figures of the previous week. The measles deaths are now below the 100 limit.

No printed return has yet been issued for the week ended May 1st, 1926, but we are able to give the total notifications of infectious disease for London and for England and Wales as a whole. In London there was notified no case of small-pox; scarlet fever, 211; diphtheria, 242; enteric fever, 9; pneumonia, 117; puerperal fever, 5; cerebro-spinal fever, 3; encephalitis lethargica, 4; continued fever, 2; and ophthalmia neonatorum, 5. In England and Wales as a whole cases were notified: small-pox, 146; scarlet fever, 1518; diphtheria, 979; enteric fever, 44; pneumonia, 1198; puerperal fever, 42; cerebro-spinal fever, 9; acute polio-myelitis, 3; acute polio-encephalitis, 2; encephalitis lethargica, 53; continued fever, 2; dysentery, 7; and ophthalmia neonatorum, 93. In the same week 166 deaths occurred in the 105 great towns from influenza, of which 28 were in London.

# Obituary.

### STEPHEN PAGET, M.A. OXF., F.R.C.S. ENG.

Mr. Stephen Paget died at his residence, "Furzedown", Limpsfield, on May 8th, aged 70. Born in 1855, the fourth son of Sir James Paget, Stephen was educated at Shrewsbury, Christchurch Oxford, and St. Bartholomew's Hospital, whence he qualified M.R.C.S. in 1883, taking the F.R.C.S. two years later. Following his father, he became Surgeon to the West London and Metropolitan Hospitals before developing the specialty which led to his appointment as Surgeon to the Throat and Ear Department of the Middlesex Hospital. His name will be remembered chiefly as the founder in 1908 of the Research Defence Society, a reincarnation of the earlier Association for the Advancement of Medicine by Research which his father had helped to inaugurate 25 years earlier. For many years under his inspired leadership as Secretary and later as Vice-Chairman this Society has striven to make generally known the value and necessity of animal experiment. The active prosecution of medical research being debarred to him by ill-health, the protection of other workers from undeserved attack became his chief life work. His publications, which include a memoir of his father and a biography of Sir Victor Horsley, reflect this bias but differ from most propagandist literature in the grace and charm of their style. His essays are delightful and Confessio Medici, first published in 1908, has become a classic cherished by medical men and reread perhaps more often than any other book on their shelves. Stephen Paget lived to see the need for experimental work accepted by nearly all his colleagues and by a large section of the thinking public.

## V.D. CLINICS AND THE L.C.C.

*To the Editor of* THE LANCET.

SIR,—With regard to my letter on this subject in your issue of April 3rd (p. 735), the chairman of the Public Health Committee of the London County Council has asked me to write and explain that it is not the intention of the County Council to concentrate entirely on six whole-time clinics, and that those clinics which are to be closed will receive one year's intimation of the fact.

I am, Sir, yours faithfully,

STELLA CHURCHILL.

*Chiswick, W., April 29th, 1926.*

# Vacant Appointments.

**Elizabeth Garrett Anderson Hospital,** Euston-road.—Wanted, fully qualified Medical Women for the following posts: HOUSE PHYSICIAN, OBSTETRIC ASSISTANT, and HOUSE SURGEON. Salary at the rate of £50 per annum, with board, residence, and laundry. Appointments from 1st July for six months. Applications, with three copies of testimonials, to be sent to the Secretary before 26th May.

IMOGEN H. MURPHY, Secretary.

**Applications are invited for the Chair** OF ANATOMY at the Royal Veterinary College, Camden Town, London, N.W. 1, which will be vacant at 1st October next. Salary £600 per annum, plus Superannuation benefits. Applications, accompanied by not more than four testimonials, should be addressed to the Secretary, and received not later than 1st July.

# Medical News.

## THE STRIKE IN LONDON.

University of London.—The Final Examinations, normally held in June, for Internal and External Students, have been postponed to a date not earlier than Sept. 1st. The first day of the recent final M.B., B.S. examination coincided with the first day of the stoppage of transport. In spite of this only four or five candidates—some two per cent. of the entry—failed to present themselves punctually for papers and practical tests. Common difficulties of transport appeared to lead to more fraternisation between examiners and candidates than is usual on these formal occasions. and lifts in private vehicles labelled "M.B., B.S. Examination Hall" were exchanged.

British Medical Association.—The Association inform us that they asked for suggestions from the Ministry of Health and the Home Office as to any way in which the Association could be helpful during the emergency. They were informed that there was no central way in which the organisation could be used, but that doctors could serve best by placing themselves at the disposal of the police authorities in their own neighbourhoods.

London School of Medicine for Women.—At this School work was carried on as usual. Several of the students and members of the staff volunteered for public service and such occupations as might usefully free men for work as special constables, etc., but it was not found necessary to call on them.

The emergency duties assumed by medical students in London were manifold and varied. Students were feeding horses, staffing restaurant-cars and driving food lorries. One squad of students were taught the technique of train signalling in 48 hours, and were sent to Exeter to carry on this work. Others did duty as porters, while a large number were serving as full time special constables. One of the latter is in St. Thomas's Hospital with a punctured wound of the back.

The Metropolitan Borough of St. Pancras collected the names of doctors available in case of serious civil commotion.

37 young consultants from the Harley-street area enrolled in the Metropolitan Special Constabulary Reserve, Marylebone, D. Division.

The almoners at one of the big London hospitals had so little to do in the absence of large attendances of out-patients, that they used the opportunity to prepare the year's accounts and statistics.

## THE STRIKE IN PROVINCIAL CENTRES.

We have received from correspondents the following information on the effects of the industrial disturbance. *Newcastle-on-Tyne.*—At the Royal Victoria Infirmary cases of accident or injury were few, the electrical supply was maintained by volunteers, and the chief anxiety was financial; the workers' weekly contributions are an important source of income. Lectures at the medical school were suspended as all the students were on public service. Vegetables and some medical necessaries became somewhat scarce. *Cardiff.*—Work at the Infirmary and the medical school proceeded on normal lines. *Liverpool.*—The hospitals were little affected. There was a shortage of coal, but fresh meat was obtainable in spite of slaughtermen leaving work. *Leeds.*—No emergency medical services were needed. The General Infirmary's activities were unhampered; medical students, with few exceptions, continued their studies; there was no restriction in food, and the sanitary conditions of the city remained satisfactory. *Sheffield.*—The hospitals did not suffer in service or supplies, but it was estimated that the industrial dispute would inflict on them a loss of £1500 a week under the 1d. in the £ scheme. Food supplies were maintained. The university continued its work, but many students undertook civic duties. *Bristol.*—The emergency hardly affected the hospitals. Although a large proportion of the medical students volunteered for service only a few of the final year students were called away. There has been practically no evidence of distress amongst the families of those involved in the conflict. *Nottingham.*—There was no interference with hospital or private practice. Straitened conditions of livelihood have as yet produced no perceptible effects. *Aberdeen.*—General conditions remained fairly normal. There were no special difficulties in carrying on medical work. Many students went on public service. *Glasgow.*—The work of general, Poor-law, and other hospitals proceeded smoothly. The cars of doctors were occasionally held up but were always allowed to proceed. No difficulty arose in connection with sanitation and the food supply was adequate. *Manchester.*—There was no dislocation of medical services or the provision of necessaries.

# Medical Diary.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Wednesday, May 19th.—5 p.m., History of Medicine. Annual General Meeting. Election of Officers and Council for 1926–27. Mr. Walter G. Spencer: Celsus de Medicina.

Thursday,—5 p.m., Dermatology. (Cases at 4 p.m.) Annual General Meeting. Election of Officers and Council for 1926–27. Cases, Dr. Semon: Case for Diagnosis. Dr. Kingston: Premycotic stage of mycosis fungoides. Dr. Barber: Reticulated pigmented poikilodermia (Civatte).

Thursday, May 20th.—8.15 p.m., Electro Therapeutics and Rontgen Society. Dr. A. Dauvillier (Paris): The Measurement of X-ray Dosage. (Mackenzie Davidson Memorial Lecture).

Friday—5.30 p.m., Electro-Therapeutics. Annual General Meeting. Election of Officers and Council. Dr. H. Eaton Stewart (New Haven, U.S.A.) Diathermy in Pneumonia.

ST. MARY'S HOSPITAL INSTITUTE OF PATHOLOGY AND RESEARCH.

Thursday, May 20th.—Lecture postponed.

MANCHESTER ROYAL INFIRMARY POST GRADUATE COURSE.

Tuesday, May 18th.—4.15 p.m., Mr. F. H. Westmacott: Deafness, Curable and Incurable.

Friday, 4.15 p.m., Dr. J. Cowan: *Demonstration* in Electro-therapeutics.

◆

# Deaths.

Crisp.—On May 4th, at Market Harborough, John Crisp, M.R.C.S. Eng., L.R.C.P. Lond., aged 62.

Heaton.—On May 3rd, at Cape Town, *Lieut.-Colonel* Arthur Frederick Heaton, R.A.M.C. (retd.)

Paget.—On Saturday May 8th, at Furzedown. Limpsfield, Stephen Paget, F.R.C.S., aged 70.

**TERMS OF SUBSCRIPTION, POST FREE. Payable in Advance.**

THE LANCET Annual Subscription is £2 : 2 : 0 Inland, and £2 : 10 : 0 Abroad, and Subscriptions can commence from any date. Cheques and P.O.'s (crossed Westminster Bank Ltd., Covent Garden Branch) should be made payable to the Manager, THE LANCET Offices, 423, Strand, London, England.

Pr[illegible] Watson & Viney, Ld., 52, Long Acre, W.C.2, and Published by the Proprietors, Wakley & Son (1912) Ltd., 423, Strand, and No. 1, Bedford Street, Strand, in the County of London.—Saturday, May 15, 1926.

# An Address

ON THE

# MEDICAL ASPECTS OF TOBACCO.

*Given before the Harrogate Medical Society on April 10th, 1926,*

BY SIR HUMPHRY ROLLESTON, BART.,
K.C.B., M.D. CAMB., F.R.C.P.,
REGIUS PROFESSOR OF PHYSIC, UNIVERSITY OF CAMBRIDGE.

THE medical aspects of tobacco interest us all in our capacity as medical advisers of others, and, in addition, probably a certain proportion from a personal point of view. As in the case of alcohol, our opinions are inevitably coloured by our own tastes, for the teachings of the laboratory cannot always be rigidly applied to human practice or correspond with the empirical lessons of a lifetime. Animal experiments cannot well take into account idiosyncrasies, and with regard to alcohol and tobacco personal peculiarities are so important that they must often over-rule any hard-and fast laws.

## HISTORY.

Tobacco-smoking is very ancient, and its history shrouded in the obscure clouds of its own smoke, for it has existed in South America (Orinoco) and the West Indies from very early times; and in China old undated monuments bear engravings of pipes. In North America there is a tradition that during a time of dire famine a heaven-sent maiden descended among the Hurons and wrought a miracle by causing Indian corn, potato, and tobacco to spring up. In 1492 Christopher Columbus not only discovered America but the island of Tobago and the chiefs of Cuba in the act of puffing rolls of tobacco leaves, a primitive form of cigar called "tobago." The Spaniards learnt smoking in America about 1560, and it was first introduced into England by Sir John Hawkins in 1565 or by Sir Francis Drake and Sir Walter Raleigh in 1585. Jean Nicot (1530–1600), the French Ambassador to Sebastian, King of Portugal, sent some tobacco seeds which he obtained from a Flemish merchant at Bordeaux, to Catherine de Medici in 1559, and thus led to its use in France and to the immortalising of his own name in those of the plant, *Nicotiana tabacum*, and of nicotine—one of the many instances of man getting more credit than is his due. Dr. C. Singer, however, points out that André Thevet, in his "Singularitez de la France antarctique autrement nommé Amerique" (Paris, 1558), stated that he brought the seeds of the tobacco plant to France and started growing it there in 1556, or three years before Nicot. About this date Cardinal de Sainte Croix, Papal Nuncio to Portugal, and Nicolo Tornaboni, Nuncio to France, first introduced tobacco into Italy as a cure for the morbus gallicus (syphilis) and called it the "herbe sainte." The name tobacco has also been derived from the language of the island of St. Domingo. "Tobacconist" originally meant one who smokes and not the seller of the commodity. The word "cigar" probably comes from the Spanish "cigarrar" (to roll) and the spelling "segar" occurs in Twiss's "Travels through Spain" (1783) and is not unfamiliar now.

The use of tobacco since its introduction into this country from America by Sir Walter Raleigh in 1585 has, like other innovations, good or bad whichever it may seem to you, excited opposition as well as welcome. Henry Buttes, "Master of Artes and Fellowe of C.C.C. in C.," in his "Dyets Dry Dinner Consisting of eight severall Courses" (1599), made tobacco the last course and said that "it cureth any grief dolour, opilation (obstruction), impostume, or obstruction proceeding of cold or winde." King James I., in his famous counterblast (1604), vigorously condemned it; Raphael Thorius, a Fellow of the Royal College of Physicians and a devotee of tobacco, wrote "Hymnus Tabaci sive de Pacto" (1627), and with Matthew Gwinne, also a Fellow of the College and a poet, had the hardihood to argue in favour of the weed in a medical disputation held at Oxford for the edification of James I. in 1605. William Barclay, Mr. of Art and Doctor of Physicke, in "Nepenthes or The Vertues of Tobacco (Edinburgh, 1614), recommended it for many diseases, dropsy, arthritis, gout, epilepsy, and as an "antidotte of hypochondricall melancholie"; he must have been rather an optimist, for he continues: "It prepareth the stomache for meat; it maketh a clear voice; it maketh a sweet breath," and after further extolling its medicinal powers, "in few words it is the princesse of physical plants." In 1615 the Vice-Chancellor of Cambridge found it necessary, as, indeed, he probably would even in these more enlightened days, to proclaim that "no graduate, scholler, or student presume to take tobacco into St. Mary's Church, upon payne of finally expellinge the University," and Charles II. forbad Cambridge men "to wear periwigs, smoke tobacco or read their sermons." In "A brief and accurate Treatise concerning the taking of the Fume of Tobacco which very many in these dayes doe too too (sic) licenciously use" by Tobias Venner, Doctor of Physicke in Bathe (London, 1637), it is written "Indians call it petun or petum, which indeed is also the fittest name that both we and other nations may call it by, deriving it of peto, for it is farre fetcht and much desired. And thus much for the name." He adds that "it is hot and drie in the third degree, and hath a deleterialle, or venemous qualitie, as I suppose: for it being any way taken into the body, it tortureth and disturbeth the same with violent ejections both upwards and downwards, astonishes the spirits, stupifieth and benummeth the senses and all the members. To conclude, therefore, I wish them that desire to have mentem sanam in corpore sano, altogether to abandon infanum praeposterumque Tabacci usum." In 1624 Pope Urban VIII. published a decree of excommunication against snuff-takers and Innocent XII. extended this to smokers in 1690. In the interval (1634) smoking had been prohibited in Russia on pain of having the nose cut off. Strange as it may appear, Oliver Cromwell and the Puritans smoked tobacco, though the Society of Friends and the Salvation Army banned this form of indulgence. As recently as the early 'fifties in the last century tobacco was at a very low ebb in this country; snuff was going out of fashion, and the increasing practice of smoking was regarded by society as a low, vulgar habit suitable, indeed, for labourers, Bohemians, and the scum of society, thus re-echoing King James' "surely smoke becomes a kitchen far better than a dining chamber." In 1857 there was much discussion in THE LANCET on "The Great Tobacco Question: Is Smoking Injurious to Health?" In the previous year Samuel Solly, F.R.S., surgeon to St. Thomas's Hospital, asserted that it was one of the causes of general paralysis, and in the correspondence that later raged he quoted three cases of delirium tremens in non-alcoholics in the hospital due to smoking, and stated that it caused spermatorrhœa, a condition then attracting undue attention. A more modern and very keen anti-tobacconist, H. H. Tidswell, who regretted that he acquired the habit in the medical school of St. George's Hospital, considers that "it may truly be described as suicide or self-destruction by early instalments," and regards it "as a form of narcophilia which may soon develop into narcomania dulling the intellect and poisoning their wives by their smoky breath, thereby causing sterility," thus recalling the lines in the well known "Ode to Tobacco,"* which appeared in C. S. Calverley's "Fly-Leaves."

---

* It is interesting to note that according to Mrs. L. Creighton (Life and Letters of Thomas Hodgkin, 1917, pp. 19, 148) this ode was really written in 1840 by Hodgkin's two Quaker sisters aged 16 and 17 for an essay society at Tottenham and was unsigned. Misled by the close resemblance to his style, a friend of Calverley's caused them to be published as his in "Temple Bar" in about 18[illegible]. Calverley died in 1884. For a collection of amusing verses reference may be made to Walter Hamilton's "Poems and Parodies in Praise of Tobacco," 1889.

"How they who use fusees
All grow by slow degrees
Brainless as chimpanzees,
Meagre as lizards.
Go bad and beat their wives,
Plunge (after shocking lives)
Razors and carving knives
Into their gizzards."

At the present time there is a vigorous anti-tobacco crusade in the United States of America, where, in 1913, it was calculated that the yearly consumption was 5·59 lb. per head of the population, as against 2 lb. in this country. There is thus, as in other ways, a parallelism of the views held about alcohol and tobacco, but it is at least doubtful if prohibition in America will embrace weeds as well as wine.

Pipe-smoking is, of course, a very ancient way of using, or, as it was once expressed, drinking, tobacco, as the finds in prehistoric graves testify. Makeshift pipes of very various kinds, such as the rather grim utilisation of the thigh bone of a child or the more commonplace knuckle bone of a lamb, are described in "The Pipe Book," by Alfred Dunhill; the earliest written accounts of a tobacco pipe are those in Gonzalo Fernandez de Oviedo y Valdes' (1478–1557) "Natural Hystoria de las Indias" (1526) and Jacques Cartier's narrative of the exploration of the St. Lawrence estuary (1536); the first refers to a Y-shaped tube the two prongs of which were apparently held in the nostrils, thus confirming the view that smoking was evolved from inhalation, and describes as a very bad vice that of the Indians in taking the smoke, which they call tabaco, in order to lose consciousness; Cartier describes the Indians using "a hollow piece of stone or wood like a pipe—i.e., like the musical instrument which that name denotes." Some of the prehistoric pipes were straight and more like the modern cigar- or cigarette-holder than the now familiar pipe.

Cigars of scents were smoked in India in the seventh century A.D., but the rolling up of tobacco leaves appears to have been initiated later, though it was in existence when America was discovered; Thevet in his "*Cosmographie Universelle*" (1575) gives an illustration of Indians smoking cigars shaped like cornucopias. Cigar-smoking was popularised in this country by officers who learnt it in Spain during the Peninsular War (1808–14), and cigarettes were similarly brought from the East as a result of the Crimean War (1854–56), but did not become really common until 30 years later. The first well-known man in society to smoke cigarettes was Laurence Oliphant (1829–88), the brilliant mystic and author who brought the habit from Russia. The influence of war is shown by the much greater frequency of women smokers during and since the Great War, and as perhaps an aftermath the recent action of some railway companies in relaxing the regulation against smoking in waiting-rooms and labelling some carriages "non-smoking."

Tobaccos vary considerably in their nicotine content; Cavendish tobacco contains 4·15, Latakia 2·35, and mild honeydew 1·6 per cent. According to THE LANCET's analysis, pipe mixtures have the highest nicotine content, and British cigars a higher than Havana. The nicotine content of the tobacco and of its smoke, however, do not vary directly, the way in which the tobacco is smoked and the degree of combustion being the important factors; thus Virginia cigarette tobacco contains (1·4 per cent.) nearly twice as much nicotine as Manila cigar tobacco, and yet the cigar smoke contains more than double the amount of nicotine in the cigarette smoke (Dixon); the smoke of Virginian cigarette tobacco contains 0·06 per cent. only of its nicotine content when smoked as a cigarette, but when burnt in a pipe 37 to 53 per cent. of its nicotine content. The degree of combustion is most complete in cigarettes of all kinds, least in a pipe, and midway in the case of cigars. In pipes as much as 70 to 80 per cent. of the nicotine in the tobacco may pass into the smoke; a good deal, however, turns on the length of the mouth-piece; a long pipe is, therefore, better than a short one; thus a clay pipe or a churchwarden allows the nicotine to condense in the stem to such an extent that very little passes into the smoke. As the nicotine collects in the moist area of the cigar behind the burning tip, and may, if it does not undergo complete combustion, be carried into the mouth by the hot smoke, a thick or moist green cigar is more harmful than a thin or a dry one, and the bitter end should be abandoned and a half-smoked cigar not re-lit. It has been stated that a smoker who re-lights a pipe or cigar absorbs more poison than he would from ten ordinary smokes (Kionka). According to Dixon the smoke of one cigar contains as much nicotine as 12 to 18 cigarettes.

### COMPARATIVE EFFECTS OF PIPES, CIGARS, AND CIGARETTES.

The general opinion is that cigarette-smoking is the form likely to give the worst results, then cigars, and lastly, pipes. On the other hand, the order has been reversed; the evil reputation of cigarettes has been ascribed by Turney, who speaks of them as "the smokers' L.S.A.," to their patronage by the unstable neurotics who are unable to stand cigars and pipes. Two reasons given for the more evil influence of cigarette-smoking are: (1) that many more cigarettes than pipes are smoked, and (2) that cigarette smoke is inhaled, whereby *nicotine and carbon monoxide* are more certainly introduced into the body, and furfurol exerts its irritating effect on the mucous membrane of the nasopharynx, and produces a smoker's throat and cough. According to Armstrong, cigarette smoke contains up to 1 per cent. carbon monoxide, but more when smoking is rapid than slow; a Havana cigar smoked quickly giving as much as 8 per cent., or the same as in South Metropolitan gas. The blood of cigarette smokers may show CO absorption even up to 5 per cent. (Dixon). On the other hand, cigarette smoke is diluted more freely with air than pipe smoke, 80 as compared with 50 per cent., and a heavy cigarette-smoker commonly consumes less tobacco than a pipe- or cigar-smoker; often he is like a patient with a tic and throws the cigarette away when half smoked, so that the larger the number of cigarettes used the smaller is the amount of each smoked. The content of nicotine in cigarette smoke is much less than that in the smoke of pipes, that of cigar smoke being between these two extremes. The effects of cigarette-smoking appears to be chiefly due to carbon monoxide (Dixon), pyridine, furfurol, and ammonia, whereas cigar smoke is powerful mainly on account of its nicotine content. There appears to be some divergence of opinion as to the influence of the cigarette paper; some say that it is harmless, others, as Kionka, that the paper collects the products of distillation, which are volatilised and absorbed. Virginian cigarette smoke contains furfurol, and THE LANCET analysis states that one cigarette will provide as much as two ounces of whisky, while Turkish cigarettes supply very little, and cigars and pipe tobacco none. Furfurol, pyridine derivatives, ammonia, and carbon monoxide are distillation products from vegetable material and are not, like nicotine, in any way special to tobacco, but by their irritating effects on the mucous membrane of the throat and upper air passages may in some way account for the evil reputation of cigarettes. Cigar-smoking usually gives a much greater feeling of satiety than cigarettes or even pipes. Much, no doubt, depends on the condition—moist or dry—of the weed, and whether or not it is smoked to the bitter end; the state of the pipe, clean or foul, and the length of the stem also bear on the effects produced. Cartridges or plugs, as in Sir Morell Mackenzie's and other hygienic pipes, which seem to have gone out of fashion, to absorb the products of combustion, may diminish the bad effects. The other methods of "using tobacco," an old East country expression now, like others, not only naturalised but surviving in America—namely, chewing and snuffing—are said to be attended by so little absorption of nicotine as to be comparatively free from untoward symptoms.

*Tolerance* to smoking tobacco is usually acquired within a short time, and according to Dixon and Lee is due to slow destruction of nicotine by a ferment, and so long as destruction keeps pace with absorption toxic symptoms are avoided. But idiosyncrasy to the effects of tobacco is not uncommon and may be quite active and prevent acquisition of tolerance or only render the individual indifferent. Though tolerance may be lifelong, it often diminishes with advancing years, especially, I fancy, with the presence of arterio-sclerosis; hence, old people give up the habit as the result of experiencing unpleasant symptoms, such as giddiness, cardiac irregularity, or pain. Idiosyncrasy shows itself in the curious way in which some persons can smoke a considerable amount of tobacco in the form of cigarettes, but none in a pipe or as a cigar. Tolerance may be modified or even abolished by disease; for example, influenza. Sometimes a confirmed smoker may, without being conscious of a change in the quantity or quality of the tobacco smoked, be knocked over, as if he were a novice. Kionka considers that the tolerance is of a limited character, and that when a seasoned smoker oversteps the mark he suffers more than the novice because his tissues are saturated with nicotine. The first sign of failing tolerance is a vague distaste for tobacco, which may lead to frequent trials of new brands or mixtures. It has often seemed to me that the average man has, roughly speaking, a certain capacity for smoking, and that if he is a very heavy smoker for some years, his smoking life, so to speak, is thereby curtailed. There are, of course, many exceptions, but that such a rough relation exists between consumption of tobacco and the duration of tolerance seems not improbable in the light of carbohydrate and protein metabolism, in which excessive sugary or meaty diets may in time lead to diabetes or gout.

### IS TOBACCO-SMOKING AN ADDICTION?

Tobacco-smoking becomes a habit and, no doubt, there is a considerable psychological element in the act, for a man may be quite happy, at any rate for a time, with an empty or unlit pipe in his mouth, and I have known a porcelain cigarette, resembling in appearance a chocolate one, console a constant smoker. An extreme example of the influence of the cigarette habit was a man I met *non-professionally* during the war, who told me that he smoked 100 cigarettes in the day, which, supposing each cigarette had ten minutes' life, would provide more than 16 hours' occupation daily; he had given it up with the result that his work was so interfered with that he returned to his cigarettes. The way in which cigarette abstinence interrupted his work was not, as I supposed, by making him feel restless, but by stopping his writing by his becoming conscious that his left hand was automatically fumbling on the table in front of him where the cigarette box stood in normal times. Is tobacco-smoking an addiction? Opinion on this point may differ. Prof. W. E. Dixon, who says that the inveterate cigar-smoker must continually be absorbing a small quantity of nicotine to keep his nervous system in a comfortable state, and that the constant cigarette consumer feels the need of carbon monoxide, denies that smoking is an addiction. This question turns on the meaning attached to the work "addiction," and may therefore be a verbal problem. The Ministry of Health's Departmental Committee on Morphine and Heroin Addiction (1926) defined an addict as "a person who, not requiring the continued use of a drug for the relief of the symptoms of organic disease, has acquired, as a result of repeated administration, an overpowering desire for its continuance, and in whom withdrawal of the drug leads to definite symptoms of mental or physical distress or disorder." That smoking produces a craving for more when an attempt is made to give it up, as Charles Lamb has so graphically described in "The Confessions of a Drunkard," is undoubted, but it can seldom be accurately described as overpowering, and the effects of its withdrawal, though there may be definite restlessness and instability, cannot be compared with the physical distress caused by withdrawal in morphine addicts. To regard tobacco as a drug of addiction may be all very well in a humorous sense, but it is hardly accurate.

### THERAPEUTIC USES OF TOBACCO-SMOKING.

During the Plague of London smoking was regarded as a sure protection against the disease, and women and children and boys at Eton had lessons in this prophylactic measure; even now some smokers proclaim that smoking immunises them against influenzal infection; it is true that in vitro tobacco smoke has a bactericidal effect which persists after filtration through cotton-wool, and so, as nicotine is thus removed, is due to other bodies, such as pyrrhol and formaldehyde. But in the mouths of smokers Puntoni found that tobacco smoke has very slight bactericidal powers even for micro-organisms with very little resistance to antiseptics. In the past tobacco as an enema was employed to relax muscular spasm so as to allow a dislocation to be reduced, and with rather less reason—i.e., its antiseptic properties—as an external application for many other conditions, such as wounds and ulcers, erysipelas, the itch, syphilis, and cancerous growths; and to relieve pain in rheumatism and after operations. Infusion of tobacco has occasionally been used as an abortifacient, and in Germany young women are stated to seek employment in tobacco factories with this object in view. The spasm of bronchial asthma may be reduced by smoking, but only when it is carried to a nauseating degree. Tobacco has dropped out of the British Pharmacopœia, but it certainly has its uses, especially as a sedative, as every smoker knows; it may act as a charm for the fidgets. I remember a lady in a small Scots village who only got relief from the post-prandial fidgets by smoking one of her husband's pipes, and was hard put to it to conceal this method from her servants when they came into the room unexpectedly.

### BAD EFFECTS OF TOBACCO-SMOKING.

Just as many more therapeutic uses than are now recognised have been ascribed to the use of tobacco, so, as has already been mentioned, have numerous evil effects been referred to its abuse. Now, as tobacco smoke contains nicotine, carbon monoxide, and pyridine bases, and as it undoubtedly has a familiarly striking effect on raw youths, it must be acknowledged that it, maybe, has evil effects. Some of them will be mentioned, but considering the universality of the habit and the large number of heavy smokers, the comparative rarity of undoubted lesions due to smoking is remarkable. In this respect there is a great contrast between the price paid by those who smoke and those who drink alcohol to excess. It has sometimes been argued that these methods of meeting the need for narcotics go hand in hand and that smoking leads to alcoholic indulgence, but probably few smokers would admit this indictment, and, indeed, the contrary may well be argued—namely, that as a sedative and narcotic the popularity of the tobacco habit has ousted alcoholism. But there can be little doubt that the injurious effects of excessive smoking are materially augmented by, if not in part due to, simultaneous alcoholism.

#### *Nervous System.*

Nicotine exerts, as Langley showed, a definite action on the nerve cells in the path of the autonomic nerve-fibres, first exciting and then paralysing them. It is therefore to be expected that smoking will, in virtue of the nicotine and the carbon monoxide contained in the smoke, affect the nervous
and a large number of manifestations occur in
posed persons. Binet, from a review of experi
observations, concludes that tobacco exerts a
effect on the brain. Muscular tremor, similar t
of Graves's disease or senility, can in some indi

be produced with the regularity of a laboratory experiment, and, as in the case of vertigo, have been ascribed to chronic poisoning by carbon monoxide; in others jumpiness and irritability, or neuralgia, vertigo, insomnia, or headache are produced. Mendenhall's physiological investigation of the effect of smoking, which points to the sensory and motor effects being mainly due to the contained nicotine, shows that the immediate results are conditional on the state of the sensory mechanism; when this is depressed the immediate effect of smoking is stimulation, and when the sensory mechanism is hyper-excitable smoking exerts a depressing effect. But the depressing effect on the sensory threshold is much more prominent than the stimulating influence. Motor reactions are disturbed in the direction of diminution of efficiency, especially of the finely coördinated movements. Turney describes transient motor paralysis consequent on slight over-exertion or pressure on nerves, and also accepts transient aphasia due to tobacco, but these must be very exceptional.

An important question is the influence of smoking on the higher intellectual centres; after a transient preliminary stimulating effect on mental processes, during the act of smoking, its sedative effect develops. It is rather alarming to find that in America 2000 psychological tests on medical students showed that smoking lowers mental efficiency in from 10 to 23 per cent., and especially in imagery, perception, and association. Adolphe Abrahams, while recognising that these tests may not be conclusive, believes that smoking diminishes the general capacity for work, impairs memory for names, and renders sleep less refreshing; and Turney, who admits to being a moderate smoker, considers that some of the indolence, dreamy apathy, and premature senility often seen in heavy smokers is due to their indulgence. He also refers to migraine and epileptic fits being increased by smoking and disappearing when the habit is abandoned. That psychoses are definitely due to excessive smoking is probably rarely, if ever, true; more often the constant smoking is a manifestation of the neuropathic constitution. But it would be difficult to deny that abuse of tobacco may not do harm to a neuropathic person, and so be a contributory factor.

### *Tobacco Amblyopia.*

Tobacco amblyopia, with a central scotoma more marked for colours than for white light, is regarded by Gowers as probably due to a primary degeneration of the macular fibres with a secondary retrobulbar neuritis. According to de Schweinitz, moderate smokers of 60 or over, who have not altered the quality or quantity of their tobacco, may, after a long period of immunity, suffer from the characteristic papillo-macular scotoma. While recognising the influence of the so-called cumulative effect of tobacco as a possible explanation, he regards this as unsatisfactory, and believes that sclerosis of the small nutrient arteries of the retina and optic nerves is a contributory factor. It is said that tobacco amblyopia is almost entirely due to excessive pipe-smoking, and that a foul condition of the pipe is an important, if not essential, factor; according to Weidler, though amblyopia is specially associated with the use of shag. it is but rarely solely due to smoking, alcoholism being an accessory, thus illustrating the action of two poisons combining to exert a powerful influence. Complete abstinence from both poisons and full doses of nux vomica should lead to a cure, but relapse of the amblyopia may follow if the excessive use of the poisons is resumed. It is said that in tobacco amblyopia the dilatation of the pupil resulting normally on stimulation of the skin of any part of the body is either in abeyance or obtained only by increased stimulation (Dorrell).

Deafness is ascribed to smoking and is probably due to extension of pharyngeal catarrh to the middle ear, but it has also been referred to toxic effects on the internal ear. The tinnitus of otosclerosis is increased even by very moderate smoking. It is an interesting question whether the vertigo is due to the toxic effects, including vascular disturbance, on the semicircular canals, thus being analogous to tobacco amblyopia, or whether it is central.

### *Effects on the Heart.*

On the heart the unpleasant effects of smoking may be divided into: (1) The "tobacco heart" of young smokers, characterised by palpitation, rapid action, and frequent extrasystoles. (2) Arrhythmia at any time of life and more noticeable after 50 years, when extrasystoles are common and more easily induced. The late Sir Clifford Allbutt wrote: "One case is known to us of a man whose general health is excellent, who is by no means a neurotic subject, and whose heart stands work well in all other respects, in whom intermittence of the heart may occur for many days if he remain for an hour or two in a room with many smokers. He dare not sit in a close smoking-room or in the smoking compartment of a railway carriage. The intermittence may not begin until the next day, or the next but one, but then comes on with the certainty of a laboratory experiment; it gets worse during the next day or two, and then gradually passes off in a few more days. He never suffers from any cardiac disorder unless exposed to tobacco, but this proclivity has hung about him for many years. He has no dislike to the drug, nor does he feel any immediate discomfort from it." I have no doubt that he was here describing his own symptoms, and often thought of this when he hospitably handed cigarettes to his guests ignorant of his idiosyncrasy. For the possible comfort of smokers with extrasystoles it may be mentioned that coffee also causes extrasystoles, and that the effect of abstinence from coffee and, perhaps, tea may be worth a trial before definitely deciding on "no tobacco." (3) Angina and anginoid pain due to smoking are more often seen in the later half of life. Manifestations of the more severe form of angina are said to be rare. I have seen it in two doctors fond of cigars and have heard of others. It may be noted that nicotine, unlike adrenalin, constricts the coronary in addition to other arteries, thus offering a reasonable explanation of angina. Sir Clifford Allbutt, who was rather critical of the subject, especially of Huchard's hypothesis of spasm of the coronary arteries, had seen only three well-marked cases, and obviously considered that cases of true angina had been thus described; no doubt there is a merciful tendency to take this view if possible, and it may be comforting to quote Mauriquand and Bouchat's definite dictum that angina solely due to tobacco is never fatal, but the obvious difficulty is to be certain that a given case is entirely due to tobacco. The late Sir Richard Douglas Powell and others have classed the tobacco cases as vasomotor or false angina. Minor degrees of anginoid pains, such as substernal oppression and tightness on exertion such as to stop the patient in going uphill, are not uncommon. Attacks of syncope sometimes appear to be due to smoking. The pulse of smokers is usually somewhat faster than it is, or would be, when they have given up the habit, and the average pulse-rate in smokers is some ten beats a minute faster than in non-smokers.

A point of some interest is the effect of smoking on physical efficiency. The prejudice against smoking by athletes while training is very old, and, though it is open to discussion, seems still to be on the whole generally approved. From a statistical inquiry into 304 male students at the Antioch College, Yellow Springs, Ohio, Earp found that the non-smokers were more successful both in scholarship and athletics than the smokers. From inquiry from athletes I gather that the most successful are non-smokers, and that some, but not all, are convinced from their own experience that smoking handicaps them. Adolphe Abrahams, however, from very considerable experience of athletes is not convinced that tobacco alone makes more than the most trivial difference to an athlete who trains well in other respects. An old Cambridge Blue for the quarter-mile told me that he gave it up on one occasion for a few weeks without any improvement in his time, and that Sir Clifford Allbutt told him that in his experience it took six weeks to get the nicotine out of the system. The question might arise whether or not the popular belief that smoking impairs the wind is explicable as the effect of nicotine or, as might seem more probable, of carbon monoxide combining with the hæmoglobin and so paralysing some of the red blood corpuscles

### *Blood Pressure.*

Tobacco-smoking raises the systolic blood pressure from 5 to 20 mm Hg, the diastolic pressure being less influenced; at the same time the rate of the heart is increased by about ten beats per minute The rise of systolic blood pressure is transient, and after half an hour falls to normal or below. In moderate and habitual smokers who have acquired tolerance the fall of blood pressure is gradual and the soothing effect of tobacco probably compensates for the changes, indeed, apart from any other factors confirmed smokers tend to have a low blood pressure; this has been insisted on by Dr de Havilland Hall, and according to the late Sir Lauder Brunton a systolic blood pressure of 100 mm Hg in a strong healthy man without any evidence of tuberculosis spelt excessive smoking in 19 out of 20 cases. In young people without acquired tolerance to tobacco, Prof Dixon's curves show that the initial rise of systolic blood pressure is suddenly followed by a fall which may be so considerable as to cause the familiar symptoms of collapse, which may last for an hour or more Although it is rarely seen in ordinary practice, there appears to be some evidence that tobacco-smoking produces sufficiently severe spasm of healthy blood vessels to cause definite symptoms; Erb, who described intermittent limp in 1898, ascribed it to excessive smoking, and Schlesinger and Turney confirm this view Parkes Weber considers that excessive cigarette-smoking is a causal factor in thrombo-angeitis obliterans among young non syphilitic Jews in the East End of London. Spasm appears to be induced more often and, perhaps, more readily in arterio-sclerotic than in healthy vessels, and possibly tobacco smoke may, in virtue of its nicotine content, be responsible for anginoid and cardiac pain and for angina abdominis.

Experimentally, nicotine produces definite arterial degeneration in rabbits; Huchard and others have erected the bogy of tabagism, and it has been thought that tobacco specially damages the abdominal arteries. The late Sir Clifford Allbutt, a non-smoker, reviewed the question of the causal relation to arterio-sclerosis in his open minded manner in 1915, and came to the comforting conclusion that if tobacco-smoking is a cause at all of arterio-sclerosis, it is a very slow one, at any rate to most persons, so that its effects being mingled with other conditions of senility are almost impossible of discrimination, and ten years later, in his last message, he did not find any later evidence to weaken his opinion that the effect of tobacco in causing hyperpiesis or senile atheroma, if any, is negligible

### *Alimentary Canal.*

The responsibility of irritation exerted on the lip by the hot stem of a clay pipe in causing squamous-celled carcinoma is now mainly of historic interest, as clay pipes have largely gone out of use The sore tongue and the white patches of leukoplakia on the tongue of smokers are well known, among Fournier's 321 cases of leukoplakia, 80 per cent were syphilitics, but other estimates are lower, down to 50 per cent. Among 40 cases analysed by Fox two women only were non-smokers, and 35 were habitual smokers, but syphilis appears to be an underlying cause, and is probably responsible for the great majority of the cases that go on to carcinoma.

The effect on the stomach is important; X ray bismuth meals have shown that after a short period of increased contractility the motility of the stomach becomes paralysed for an hour or so (Danielopolu); as the subjective feeling of hunger very probably depends on contractions, the relief of hunger by smoking may be thus explained; it is said that dilatation of the stomach may thus result According to Linkint the potassium sulphocyanide in smokers' saliva inhibits protein digestion, and nicotine diminishes the secretion of pepsin and rennin. Hyperchlorhydria due to pyloric spasm may be induced by excessive cigar-smoking or by pipe-smoking excessive for the individual, and thus difficulty in diagnosis from peptic ulcer may arise, perhaps more often in men about 50 In the presence of oral sepsis excessive secretion of saliva may lead to gastritis. In the rather rare tobacco dyspepsia there is from inhibition of the sympathetic exaggerated vagal action and pyloric spasm, thus imitating duodenal ulcer, tobacco dyspepsia being pressor thus differs from the other toxic dyspepsias which are depressor in character (Ryle) The comparative infrequency of tobacco dyspepsia may serve as an excuse for quoting the parody—

> "To smoke or not to smoke, that is the question,
> Whether a mild cigar assists digestion,
> Or whether it begets a kind of quaintness."

The stimulating effect of nicotine and pyridine compounds on the intestine may in intolerant young people cause rapid diarrhœa, and in seasoned individuals serve a useful purpose in promoting defecation. On the other hand, spastic constipation may result, and even enterospasm of various parts of the colon, with persistent abdominal pain most resistant to treatment other than abstinence from tobacco.

*On the respiratory tract*, tobacco-smoking is responsible for pharyngeal catarrh which may spread to the larynx and bronchial tubes, causing cough, hoarseness, bronchial catarrh, and so emphysema of the lungs. The irritating effect on the throat and upper air passages exerted by cigarette smoking has been ascribed to furfurol, pyridine, and ammonia, and not to nicotine

# An Address

ON THE

# TREATMENT OF CHOLECYSTITIS

AND THE

# PREVENTION OF GALL-STONES.

*Delivered before the Cardiff Medical Society on Feb. 17th, 1926,*

BY ARTHUR F. HURST, M.D. OXF.,
F.R.C.P. LOND.,
PHYSICIAN TO GUY'S HOSPITAL.

GALL-STONES are almost always secondary to cholecystitis, though very often the latter has completely died out long before the former give rise to sufficiently definite symptoms to warrant operation. A deposit of mucus, disintegrated epithelial cells, and bacteria forms a suitable basis upon which cholesterol can be deposited if it is present in excess in the blood or the flow of bile is impeded. Consequently the early recognition and successful treatment of cholecystitis, together with the prevention of hypercholesterolæmia and biliary stasis, should prevent the formation of gall-stones.

Gall-stones have long been known to be extremely common; they are found post mortem in at least 10 per cent. of all people dying after the age of 20. Probably over 20,000 people now living in the City of Cardiff have gall-stones or will have them before they die. But it has only recently been recognised that cholecystitis is also very common—in both sexes and at all ages, except in children. It must, in fact, be much more common than gall-stones, as the latter are always preceded by cholecystitis, though cholecystitis is only followed by gall-stones in a small minority of cases. My own experience in the last five years has indeed convinced me that cholecystitis is the most common of all chronic abdominal disorders—considerably more common than chronic appendicitis.

## DIAGNOSIS.

A diagnosis of cholecystitis can be suspected from a study of the history and symptoms if the details are skilfully elicited. It can generally be confirmed by physical examination. Laboratory and other accessory methods are of value in settling the diagnosis in doubtful cases, in determining the nature of the infection, and giving other information, which may be of great practical importance in settling the details of treatment.

### (a) *Symptoms.*

The onset of symptoms is generally gradual and often dates in women from pregnancy; sometimes successive pregnancies have been followed by a recurrence or aggravation of symptoms. What Moynihan described several years ago as the "inaugural symptoms" of gall-stones are now recognised to be the symptoms of the preceding cholecystitis, and are quite independent of the presence of stones. They can be summarised under the popular designation of flatulent dyspepsia. The patient complains of an uncomfortable sensation of fullness in the epigastrium after meals, which he believes to be due to wind, but as his interpretation of his sensations is erroneous, his efforts to relieve himself by belching are futile and only result in aerophagy. The discomfort generally comes immediately after meals; when, however, it is associated with reflex hyperchlorhydria, it simulates the hunger pain of duodenal ulcer, beginning two or more hours after a meal and being then relieved by taking more food, by alkalis, and by vomiting, though in each case less completely and less rapidly than with duodenal ulcer. Vomiting is not uncommon, especially in women; it is generally preceded by nausea and often occurs in the absence of any pain, which is quite unlike the much less common vomiting in gastric and duodenal ulcer. Nausea is very frequently present; it may be the only symptom, cholecystitis being the most common cause of chronic nausea.

The symptoms rarely disappear completely, and do not show the periodical recurrence so characteristic of duodenal ulcer. But acute or subacute exacerbations are quite common. When these are severe there may be a slight rise of temperature for a few days, sometimes accompanied by slight leucocytosis. Occasionally the chronic constipation generally present is replaced by sudden diarrhœa during these attacks.

Although the dyspeptic symptoms are generally epigastric, the patient often complains of an aching sensation in the region of the gall-bladder and less frequently in the back, especially near the angle of the right scapula.

Acute attacks of pain, whether in the epigastrium or further to the right, coming suddenly at any time, but especially in the early night, and disappearing rapidly after persisting from a few minutes to several hours, are generally due to the presence of gall-stones, but they may also occur in uncomplicated cholecystitis. The occurrence of jaundice, however slight, in attacks of this kind strongly points to gall-stones.

### (b) *Physical Examination.*

The four quadrants of the abdomen should be successively palpated. The patient should be asked no questions, but his face should be watched. If cholecystitis is present no change in expression will be observed until the right upper quadrant is reached. The hand is placed flat on the abdomen with the fingers pointing upwards below the left costal margin whilst the patient takes a deep breath; however deeply the fingers press no resistance is encountered, and it is obvious from the patient's face that no discomfort is felt. The manœuvre is now repeated on the right side: it is at once recognised that the rectus muscle does not "give" to the same extent; the patient may look uncomfortable, and when told to take a deep breath the inspiration is suddenly arrested and an expression of acute discomfort is seen. Palpation is next carried out on the right side in three segments; it is found that pain is only produced during deep inspiration with the middle one, or sometimes the middle one and to a much less extent the inner one, but not at all with the outer one. This is conclusive evidence that cholecystitis is present; it is due to the tender gall-bladder being brought into intimate contact with the fingers when the liver descends. I have repeatedly demonstrated this sign to a class of students, even when the history obtained by the clinical clerk had not led me to suspect the presence of cholecystitis and the patient had never suffered from any pain or discomfort on the right side; subsequent investigations have almost always confirmed the diagnosis.

The increased tenderness is often accompanied by referred tenderness over the eleventh rib, at the angle of the scapula, and to the immediate right of the spinal processes of the eighth to the eleventh dorsal vertebræ, and, as Ryle has demonstrated, over the third to the tenth spinal processes.

### (c) *Accessory Methods of Diagnosis.*

(1) *Examination of Bile and Duodenal Contents.*—Meltzer's discovery in 1917 that the introduction of magnesium sulphate into the duodenum leads to the contraction of the gall-bladder and relaxation of the sphincter of the common bile-duct suggested to Lyon that specimens of human bile might be obtained for investigation by this means. We have now used it in over 250 cases, and have come to the conclusion that it yields very valuable information; in the majority of cases the pathological investigations were carried out by Dr. F. A. Knott. We have very rarely failed to introduce the tube into the duodenum, and the proceeding is no more unpleasant for the patient than a fractional test-meal. The sterilised Einhorn tube is swallowed up to the 23-in. mark first thing in the morning before the patient has had anything to

eat or drink. The stomach is emptied and then washed out with sterile water, the last washing is kept for bacteriological examination in order to exclude the possibility of contamination. The tube is then slowly paid out up to the 28½ in. mark, which allows sufficient length for the duodenum to be reached Samples are aspirated every quarter of an hour until the comparatively abundant, acid, turbid, and colourless fluid present in the stomach is replaced by the very small quantity of neutral or alkaline, clear and bile-stained fluid present in the duodenum. The pylorus is generally passed in less than half an hour, and more than an hour is rarely required The first duodenal specimen is kept for examination, the duodenum is then washed out with sterile water, and from 2 to 4 drachms of magnesium sulphate in 25 per cent. solution are injected through the tube. An abundant flow of pure bile rapidly ensues. This is aspirated and the tube is withdrawn.

In the absence of gall bladder disease the bile and duodenal contents very rarely contain any pus cells, and still less frequently cholesterol crystals, but often a few columnar epithelial cells and a little mucus. If squamous epithelial cells are found the specimen is rejected, as their presence indicates contamination with swallowed spittle. Unless achlorhydria is present the duodenal contents are generally sterile or contain a few staphylococci, most of which are dead. A few colonies may grow very sluggishly and probably represent the survivors of the swallowed bacteria which have not been killed by the gastric juice. The *M catarrhalis* was never found, being apparently always destroyed in the stomach. In patients with achlorhydria, whether they have gall bladder disease or not, numerous bacteria are found in the duodenum, especially *B coli*, which appears under these conditions to ascend very frequently from the colon to the duodenum, but streptococci are rarely discovered unless the patient is suffering from Addison s anæmia or subacute combined degeneration of the cord

In gall bladder infections the bile and duodenal contents often contain pus cells, together with a larger number of columnar epithelial cells and more mucus than is generally found in normal individuals. Cholesterol crystals are frequently found in the bile of patients with gall-stones, but rarely in uncomplicated cholecystitis, and in not a single one of 70 consecutive cases in which there was no sign of cholecystitis or gall stones. In cholecystitis the bile contains bacteria, generally of a single variety, the most common infecting organism being a coliform bacillus. Streptococci have only been found in exceptional cases, and not at all in the first 100 consecutive observations carried out by Knott and Venables.

A coliform bacillus was isolated in only 7 per cent of 300 specimens of saliva examined by Glynn and Digby (125) and Knott (175), and as in no case of gall bladder infection examined by Knott was a coliform bacillus found in the spittle, it is clear that its discovery in the bile is very rarely, if ever, due to accidental contamination with swallowed saliva.

The type of coliform bacillus isolated from the bile was accurately determined by Knott in 36 cases; in 16 of these in which cholecystitis was present a pathogenic coliform bacillus was found 15 times (*B coli communis*, 12, *B typhosus*, 2; *B lactis aerogenes*, 1) and a non pathogenic coliform bacillus only once (*B acidi lactici*) whereas in 20 specimens obtained from patients who had no gall bladder disease only 6 were pathogenic, the remainder being of various non pathogenic types. The bacteria in the latter group were probably due to contamination of the gall bladder bile with the duodenal contents, as in 15 there was a low gastric acidity or actual achlorhydria which favours infection of the duodenum, both ascending from the bowel and descending from the mouth.

Whenever the gall bladder has subsequently been removed at operation, the same kind of cells and the same bacteria have been found by Knott in its contents as were discovered in the bile obtained through the duodenal tube

The following is one of our two cases in which *B typhosus* was isolated from the bile obtained through a duodenal tube; in the other the patient had suffered from periostitis of the tibia since a febrile illness, presumably typhoid fever, which he had contracted in Gallipoli ten years before.

*Typhoid Cholecystitis and Cholelithiasis, in which B typhosus was discovered in the Bile obtained by Duodenal Intubation 23 years after Typhoid Fever* —A lady, aged 40, was admitted to New Lodge Clinic in March 1925, on account of abdominal symptoms, which dated from an attack of typhoid fever in 1902, and which had become so severe during the last few years that her life was miserable and she had had to give up all her social activities. Gastroptosis, movable kidney, and appendicitis had been suggested as possible causes of her symptoms, which consisted in almost constant pain in the epigastrium and right side of the abdomen and back, often associated with severe headache and sometimes culminating in severe attacks with nausea and vomiting. She had become much weaker and so nervous that the condition had been regarded as possibly a pure neurosis for which psychotherapy was tried without benefit

*On admission* nothing abnormal was found on abdominal examination beyond some tenderness in the region of the gall bladder The duodenal contents were very slightly bile-stained contained no leucocytes or epithelial cells, and were sterile The contents of the gall bladder, obtained after injecting magnesium sulphate, were found by Dr Knott to consist of dark bile with a heavy deposit of mucus, containing a few columnar cells and cholesterol crystals with granules of bile pigment, but no leucocytes. Cultures gave a pure growth of a typical *B typhosus* which gave a positive Widal reaction in a dilution of 1 in 100

X rays showed the presence of a shadow in the right hypochondrium, which was clearly a gall-stone, and which corresponded exactly with the most tender point in the abdomen. The cæcum was situated in the pelvis, and on rectal examination the visualised appendix was found to be acutely tender Inflation of the colon produced pain in the right iliac fossa and epigastrium (Bastedo's sign) The X rays showed no abnormality in the stomach; a fractional test-meal gave a normal curve, and no occult blood was found in the stools.

Three stools had been examined without discovering typhoid bacilli but in view of their presence in the bile a further search was made in plate cultures prepared from an incubated emulsion of fæces; a few colonies of typical *B typhosus* were now discovered, which were agglutinated by standard sera.

The gall bladder and appendix were removed by Mr Dodds Parker The former contained three moderately large black stones, consisting almost entirely of pigment. The mucous membrane was eroded and the walls showed chronic inflammatory changes Cultures from the bile, interior of the stones, and submucous tissue all gave typical *B typhosus* together with a smaller number of *B coli* The appendix showed fibrosis but no sign of recent inflammation, and cultures of its contents gave *B coli* and enterococci only

A strongly hæmolytic staphylococcus was isolated in the bile of a patient who was sent to us for severe anæmia, and recovery followed medical treatment of the cholecystitis.

*Severe non Addisonian Anæmia caused by Infection of the Gall bladder with a Hæmolytic Staphylococcus Recovery under Medical Treatment* —Mrs. H. aged 41, came into New Lodge Clinic for symptoms of exhaustion in April 1925 In 1916 she had had attacks of pain in the right hypochrondrium, accompanied by alternating diarrhœa and constipation with passage of mucus and bright red blood. Colitis was diagnosed in 1917 and her condition improved with treatment, but ever since 1916 she had been unfit and depressed and had felt abnormally tired. Though there had been no recurrence of severe pain she still suffered from epigastric discomfort after meals. In August 1924, she had an acute attack of giddiness, and had since been unable to leave the house except in a bath-chair Even indoors she could do very little on account of fatigue.

On investigation she was found to be anæmic. The hæmoglobin percentage was 47 and the red corpuscles numbered 1,020 000 per c.mm. giving the low colour-index of 0 58 this together with the very slight degree of anisocytosis and poikilocytosis and absence of megalocytes and nucleated cells excluded Addison's anæmia. The white corpuscles were normal in number and gave a normal differential count

A fractional test meal showed complete achlorhydria even after preliminary lavage; an ordinary test meal had shown that free hydrochloric acid was absent already in 1917 It is unusual to find achlorhydria in any form of anæmia other than Addisonian but the absence of any yellow coloration of the skin, enlargement of the spleen, or sign of Hunterian glossitis, together with the blood picture, seemed definitely to exclude Addison's anæmia.

The gall-bladder bile obtained through a duodenal tube after injecting magnesium sulphate contained leucocytes, but no crystals, and on cultivation a pure growth of a hæmolytic *Staphylococcus aureus* was obtained. Although no red corpuscles were seen the bile contained hæmoglobin, due presumably to the breaking down of red corpuscles, present with the leucocytes in the inflammatory exudate from the gall-bladder mucous membrane, by the staphylococcal hæmolysin. This discovery was so unusual that the investigation was repeated; on the second occasion exactly the same results were obtained. There was no doubt that the staphylococci came from the gall-bladder, as the duodenal contents obtained before injecting magnesium sulphate were sterile, which is very uncommon in patients with achlorhydria.

Nothing abnormal was found on X ray examination of the alimentary tract. The stools were normal and there was now no evidence of colitis. No other signs of disease were found.

It seemed reasonable to associate the infection of the gall-bladder with a hæmolytic staphylococcus with the development of the anæmia. As pain in the right hypochondrium was present as long ago as 1915, the cholecystitis was probably responsible for the whole of the prolonged illness.

Treatment with large doses of urotropine, an autogenous staphylococcal vaccine and non-surgical biliary drainage with magnesium sulphate for the cholecystitis, together with hydrochloric acid for the achlorhydria, resulted in rapid improvement. The hæmoglobin percentage rose to 60 in a fortnight. Although it had not risen above 66 when the patient was seen again in September, 1925, yet she was looking well and feeling better than she had done since the beginning of her illness ten years before, and she was now able to lead a life of normal activity. By February, 1926, the hæmoglobin percentage had reached 75.

Knott and Venables have shown that when gall-stones are present the evidence of active inflammation tends to disappear from the gall-bladder contents; leucocytes are generally absent and the bile is often sterile, but cholesterol crystals, which are very rarely found in uncomplicated cases of cholecystitis, are often present.

(2) *Biochemical Investigations.*—Van den Bergh's test is sometimes of use in showing the presence of slight excess of bile in the blood, which is insufficient to give rise to obvious jaundice and is below the renal leakage point, so that none appears in the urine. This is occasionally observed in cholecystitis, but it generally points to the presence of a small stone in the common bile-duct.

It is always worth while giving a fractional test-meal, as the result gives a valuable indication for treatment. In 30 per cent. of cases achlorhydria is present; this is secondary to severe gastritis or is the result of constitutional achylia gastrica. The loss of the antiseptic acid barrier of the gastric juice results in the invasion of the duodenum with coliform bacilli from the lower parts of the intestine in addition to bacteria of various types, but only rarely coliform bacilli, from the mouth and nasopharynx. This may be followed by ascending infection of the bile-passage from the duodenum. In a smaller proportion of cases (15 per cent.), and especially in those which simulate duodenal ulcer, hyperchlorhydria is present; this is probably a reflex result of the cholecystitis.

The recent investigations of Campbell at Guy's Hospital have failed to confirm the opinion expressed by Chauffard and various other authors that the presence of excess of cholesterol in the blood is evidence in favour of the presence of gall-stones. This has, of course, no bearing on the fact that the hypercholesterolæmia caused by the excessive activity of the corpus luteum in pregnancy plays an important part in the production of gall-stones in women who have had children.

(3) *X Rays: Cholecystography.*—In 1924 E. A. Graham, Cole, and Copper, of St. Louis, discovered that by the administration of certain substances, which are opaque to the X rays and are excreted in the bile, the gall-bladder could be visualised. We have already had sufficient experience to be able to confirm Graham's opinion of the great clinical value of cholecystography, and we now regard the method as one which should be employed in the investigation of all cases of possible gall-bladder disease.

Eleven different but analogous substances have so far been found which are capable of giving cholecystograms; the most satisfactory of these is sodium tetra-iodo-phenolphthalein. As the hydrochloric acid of the gastric juice precipitates the soluble sodium salt in an insoluble acid form, which irritates the stomach and intestines without being absorbed and may give rise to vomiting and diarrhœa, it should be given in 5 gr. pills coated with stearic acid or capsules treated with formaldehyde, which pass unaltered through the stomach and are dissolved in the small intestine. The sodium salt set free is absorbed into the portal circulation and is excreted in the bile. It thus reaches the gall-bladder, the mucous membrane of which absorbs water from the bile, and so leads to its gradual concentration until, about 12 hours after the pills are swallowed, a clear shadow of the gall-bladder can generally be seen with the X rays.

A dose of 5 gr. of the sodium salt is given per 10 lb. of body-weight in stout patients and 5 gr. to each 12 to 15 lb. of body-weight in thin patients, with a maximum of 100 gr. The pills or capsules are taken one at a time at intervals of a few minutes in the course of a meal at 6.30 P.M. The patient then fasts until the following morning, but he is encouraged to drink water every half hour till 9 P.M. During the whole of this period he lies on his right side. At 9 A.M. the following morning the patient, still fasting, is X rayed. He is then given a meal containing plenty of fat, such as scrambled eggs, bread and butter, and milk with cream, as fat causes the gall-bladder to contract. Two hours later he is again X rayed to see whether the gall-bladder shadow has become smaller or disappeared.

Pain in the epigastrium and, less frequently, nausea, vomiting and diarrhœa may occur, but the symptoms are never severe and do not last long. If vomiting occurs, or if the shadows of the pills are seen like lead pellets in the colon owing to their non-absorption, the test should be repeated.

We also repeat the test if no shadow is seen in spite of the apparent absorption of the drug. We prefer this to the intravenous administration of the drug, as in several cases we have observed alarming collapse follow the injection. It may be hoped, however, that before long some less toxic but equally opaque substance will be found which can be given intravenously without fear of the consequences.

When the gall-bladder is rendered visible after the administration of sodium tetra-iodo-phenolphthalein the abdomen should be palpated under the screen. By this means it is possible to determine whether any tender point under the right costal margin which has previously been discovered actually corresponds with the gall-bladder. The confirmation of gall-bladder tenderness by cholecystography is of great value, just as the analogous discovery of tenderness confined to the appendix, which has been visualised after an opaque meal, is valuable confirmatory evidence of chronic appendicitis in cases of tenderness in the right iliac fossa. In chronic appendicitis it is often possible to demonstrate that the junction of the appendix with the cæcum or some other part of it is alone tender, and in some cases of gall-bladder disease we have found that the only point of tenderness is situated over the neck. Slight pain produced by pressure exerted from the fundus towards the neck, but in no other direction, is probably due simply to increased tension in the gall-bladder and does not signify that any disease is present.

Failure to visualise the gall-bladder after the drug appears to have been completely absorbed, especially if this is confirmed at a second examination, is strong evidence in favour of obstruction of the cystic duct or of the presence of stones which completely fill the gall-bladder, unless such severe disease of the liver is present that the drug is not excreted. If the shadow is very irregular in outline, the gall-bladder is probably deformed by adhesions or fibrosis. Gall-stones can sometimes be recognised as less opaque areas on the dark background formed by the shadow of the concentrated solution of the salt in the bile, but slight mottling of the shadow does not appear to have any significance

If the shadow does not disappear or become much smaller two hours after taking a fatty meal, it can be assumed that the activity of the muscular wall of the gall-bladder is impaired owing to chronic inflammation, so that its reflex evacuation does not occur in a normal manner

The X rays sometimes give direct evidence of the presence of gall-stones. Formerly it was often difficult to decide with certainty whether a shadow seen in the right hypochrondrium was thrown by a gall-stone, a renal calculus, or a calcified tuberculous gland. Now, however, with the aid of cholecystography the relation of the shadow to the gall-bladder can be accurately determined.

If difficulty is experienced in deciding between the diagnosis of gall-bladder disease and duodenal ulcer, or it appears possible that both conditions are present together, an opaque meal should be given when the gall-bladder is being examined by Graham's method It can then be ascertained whether any tenderness which is present is localised to the gall-bladder or duodenal bulb alone or whether both are tender. By deep palpation the existence of adhesions between the gall-bladder and duodenum or stomach can be recognised, and in all cases of gastric and duodenal ulcer a constant and characteristic deformity is found.

### TREATMENT OF CHOLECYSTITIS.

Cholecystitis is due to infection of the gall-bladder; it is aggravated by biliary stasis. Consequently the treatment consists in dealing with the infection by biliary antiseptics, autogenous vaccination, and the removal of septic foci, and by the provision of adequate biliary drainage.

#### (a) *Biliary Antiseptics.*

My colleague, Dr. Knott, has confirmed the old observations of Crowe that urotropine is excreted in the bile as well as in the urine. He has shown that, although it is completely inactive in alkaline urine and serum, its antiseptic powers are unaffected by the alkalinity of bile. When used as a urinary antiseptic the urine must be kept acid in order that formalin may be set free. But unfortunately formalin irritates the bladder and leads to frequency of micturition and even hæmorrhagic cystitis. This makes it impossible to give much more than 10 or 15 gr. of urotropine three times a day for urinary infections. If, however, the urine is kept alkaline, very large doses can be given without causing any unpleasant symptoms. When it is used as a biliary antiseptic, alkalis should therefore be administered at the same time; this does not interfere with its antiseptic action on the bile, but it prevents irritation of the bladder. As the attainment of a maximal concentration of urotropine in the bile is desirable in order to disinfect the biliary tract and especially the gall-bladder, we give the patient two mixtures to be taken together after breakfast, after tea, and at 10 P.M., a glass of milk being drunk immediately after the last dose in order to prevent gastric irritation; the first mixture consists of a drachm each of sodium bicarbonate and potassium citrate in an ounce of water, and the second of 100 gr. of urotropine in an ounce of water. The first day an ounce of the alkaline mixture is taken with half an ounce of the urotropine mixture; the dose of the latter is increased by a drachm each day until a full ounce is taken If any irritation of the bladder is produced the dose of urotropine, but not of the alkaline mixture, is slightly reduced, but as a rule the patient can take the full 100 gr. of urotropine three times a day without difficulty We have only had a single case in which temporary hæmaturia occurred and the use of the drug had to be discontinued The double mixture is taken regularly for several months; occasionally the administration of the urotropine has to be interrupted for a few days, after which the dose is gradually raised again from 50 to 100 gr.

Urotropine is excreted in the cerebro-spinal fluid and has been shown to prevent the experimental infection of the central nervous system in animals. Its use clinically has in the past been limited owing to the smallness of the dose which could be safely given. During the last year we have used the method of administration I have just described for cases of encephalitis lethargica, and it might also be tried in the acute stage of poliomyelitis and other infections of the central nervous system. We have found that the enormous dose of 300 gr. a day is well borne, even by children, but it is too early to say whether the treatment succeeds in overcoming the infection.

Salicylates are also excreted in the bile and have been recommended for biliary infections. Knott's observations show, however, that it is very doubtful whether they ever exert a definite antiseptic action on the bile.

As the infecting organisms are invariably present in the bile in typhoid and paratyphoid fever, urotropine should always be given through the whole course of these diseases. The only disadvantage of giving very large doses would be that the simultaneous administration of alkalis would prevent it from exerting an antiseptic action on the urinary passages, though it is less important to secure urinary than biliary disinfection in these conditions.

If achlorhydria is present between 1 and 2 drachms of dilute hydrochloric acid should be taken in 5 to 10 oz. of water, to which the juice and pulp of an orange and some sugar are added. The first dose is taken half an hour after the magnesium sulphate to which I shall presently refer, and half an hour before breakfast; the second and third doses are taken as the daily beverage at lunch and dinner. By this means the antiseptic acid barrier of the stomach is to some extent restored.

#### (b) *Vaccination.*

When in a case of cholecystitis a specimen of bile obtained through a duodenal tube contains a pathogenic organism, a vaccine should be prepared from it and a course of inoculation carried out for several months.

#### (c) *Focal Infection.*

Although Knott's investigations showing the prominent rôle played by coliform bacilli compared with streptococci in the pathogenesis of cholecystitis throw considerable doubt on the supposed importance of focal infection in this disease, any pyorrhœa, apical dental infection, or infection of the throat, nose, or nasal sinuses should be thoroughly treated. This is especially important if achlorhydria is present, in order to reduce the danger of further infection ascending the bile passages from the duodenum, which is continually reinfected by swallowed organisms if the antiseptic acid barrier of the stomach is lost.

#### (d) *Biliary Drainage.*

Lyon and others have stated that non-surgical biliary drainage can only be procured by the direct introduction of magnesium sulphate into the duodenum through an Einhorn tube. My colleague, Dr. J. F. Venables, has, however, proved conclusively that magnesium sulphate acts just as efficiently if given in concentrated solution by mouth when fasting an hour before breakfast. Non-surgical biliary drainage is thus a method of treatment which can be easily and conveniently practised. The patient should find for himself what is the largest dose of the salt he can take without causing diarrhœa; he should avoid paraffin or other aperient and take his concentrated solution of magnesium sulphate every morning as soon as he wakes. If his bowels act regularly without aperients he will not be able to take more than half to one drachm, but if he is habitually constipated he will require 2 to 4 drachms, but he must understand that the salt is given primarily for biliary drainage and not as an aperient.

Biliary drainage can also be promoted by exercise, because the liver, as it descends in deep inspiration, is squeezed between the diaphragm and the abdominal muscles, if their tone is sufficient to offer an adequate resistance. Patients who lead a sedentary life and especially the obese should be instructed to take plenty of active outdoor exercise, and in many cases deep breathing exercises morning and evening are very useful.

If the abdominal muscles are weak an efficient support should be provided in addition to giving abdominal exercises. There is no doubt that the erect posture leads to kinking of the biliary ducts in patients with weak abdominal muscles, especially if the right kidney drops excessively or the liver twists downwards to the right on an antero-posterior axis.

### THE PREVENTION OF GALL-STONES.

The recognition and treatment of cholecystitis is the best prophylaxis of gall-stones. It is possible to go even further by trying to keep down the hypercholesterolæmia in normal pregnancy by prohibiting eggs and cream, which contain a great deal of cholesterol. It is curious that these are just the things that pregnant women are usually advised to take. These slight dietetic restrictions are clearly worth while if they serve to reduce the high incidence of gall-stones in women who have had children.

As it is impossible to tell when a gall-stone is beginning to form, it is wise, as Chauffard and his pupils have shown, to give all patients with active cholecystitis a diet poor in cholesterol. In addition to cream and the yolk of eggs, brain, liver, sweetbread, kidneys, and roe should be avoided, and all forms of animal fat should be taken in strict moderation. As many of the patients are obese this diet has the further advantage of helping them to lose weight. If, however, the patient is thin, olive oil should be given before meals, especially if hyperchlorhydria is present, as it inhibits the flow of gastric juice. It was formerly recommended in the wild hope that it would reach the gall-bladder and dissolve stones in situ, as it was found to do in a test-tube; the calcium oleate concretions found in the stools were mistaken for stones which had been expelled, but why they had fallen out of solution again was not explained. It is clear now that the patients who benefited from the olive oil treatment were those whose dyspeptic symptoms were associated with reflex hyperchlorhydria. The presence of olive oil in the duodenum also has the effect of causing the gall-bladder to contract and so promote biliary drainage, though it does this less effectively than magnesium sulphate.

Is it too rash to hope that in the next ten years the general practitioner will be able to pick out his cases of cholecystitis from the crowds of his dyspeptics with such certainty, and will treat them so efficiently, that operations on the gall-bladder will become rare events, and the morbid anatomists will regard gall-stones, like pancreatic calculi, as pathological curiosities?

# COMMON DIFFICULTIES IN LABOUR MET WITH IN GENERAL PRACTICE.*

BY HENRY RUSSELL ANDREWS, M.D., B.S., F.R.C.P. LOND.,
SENIOR OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

WHETHER as general practitioners or as obstetric members of hospital staffs, we all have one object in view—viz., diminishing the difficulties and dangers of childbirth. "Obstetrics" is the art of standing by in case you are wanted, and is one of the most important branches of preventive medicine. If it could be carried out in an ideal manner the number of abortions would be greatly reduced, the number of dead-born infants and of deaths during the first few days after delivery would be enormously reduced, the deaths of women in labour and the puerperium would be reduced to a fraction of the present rate, and the numerous disabilities that handicap women as a result of childbearing would almost disappear. Apart from the mortality from puerperal sepsis, exhaustion, shock, rupture of the uterus, &c., how many women would be saved from misery and disability if prolapse, ruptured perineum, torn cervix, and partial incontinence of urine became rare instead of filling every gynæcological out-patient department! The majority of these troubles are due to difficult labour, most of them are preventable, and it is our business to see that they are, as far as possible, prevented.

### *Prevention of Difficulties.*

The old proverb that "prevention is better than cure" is never more true than in difficult cases of midwifery. The old method was to find out the difficulty only when it was actually present, when mother and child, one or both of them, were in some degree of danger, and when it was too late to avoid the difficulty, the only possible course being to overcome it with all the skill possessed by the accoucheur. Only too often skill was not enough, and a good deal of brute force had to be used, with consequences more or less disastrous, not necessarily because of the inherent difficulties of the case but because they were present in an emergency case. It used to be quite common to hear a doctor talk almost as if he had a grievance against Providence, for having been singled out to be afflicted with the care of a large child with the breech in advance in a fat primigravida, or with an occipito-posterior position persistent to obstinacy, or some degree of contraction of the pelvis in an otherwise well-built woman, not apparent until labour had been in progress for several hours. It is no exaggeration to say that in a great many of these cases the doctor, honestly reviewing the case afterwards, was able to satisfy himself that he was in no way to blame for a dead baby and the more or less severely damaged mother. In the ideal conditions at which we are all aiming, a man who complains that he has had a very difficult labour case will be less likely to get sympathy than to be asked: Why did you allow yourself to have such a difficult case?

One way out of difficulties in labour is to perform Cæsarean section, but it is realised nowadays that Cæsarean section involves a definite mortality rate, besides certain disabilities. The modern way is to *prevent* difficulties so that they do not have to be met as emergencies, and patients are no longer treated, or rather neglected, on the doctrine of probabilities. In many "difficult" cases the difficulty is a real one, and as such should be prevented. In some, however, the difficulty is not real but is imaginary. There are many cases in which difficulty, both real and imaginary, is due to two defects: (1) want of antenatal investigation and (2) want of patience.

---

* A paper read before the Balham Medical Society on Feb. 14th, 1926.

### *Antenatal Investigation.*

In most of the serious difficulties of labour the gravity is due to the fact that the cause is found out too late—e.g., malpresentations, excessive size of the child, and contracted pelvis. If the possibility of difficulty is found out early, so that there is plenty of time to make unhurried plans to obviate it, the greater part of the danger is removed at once. Besides routine examination of the urine the essentials of antenatal investigation are: (*a*) measurement of the pelvis, and (*b*) investigation of the lie and presentation of the fœtus.

The external measurements of the pelvis are not nearly so important as the internal measurements—the diagonal conjugate and the rough estimation of the size of the cavity of the pelvis—i.e., whether the pelvis seems to be roomy or not, and the rough estimation of the transverse diameter at the outlet. In extreme cases of pelvic contraction measurements are enough—they give you warning that a living viable child cannot pass through the pelvis. In less degrees of contraction the actual number of inches or centimetres is not the most important thing, but it warns you that a careful estimation of the relative size of the head and the pelvis must be made six weeks before term. Examination at 28 weeks, a time when patients are often told that they must come to their doctor for examination, is of no great value, except that in comparatively rare cases it will confirm your opinion that Cæsarean section offers the only chance of delivery of a living child. In minor degrees of contraction of the pelvis, examination at 34 weeks, and probably again at 36 weeks, will enable you to decide between Cæsarean section, induction of premature labour, and labour at term, with occasionally the possibility of Cæsarean section if the head makes no advance after a reasonable time for moulding. These cases, in which it is felt that if all goes well—i.e., the uterus acts well and a reasonable amount of moulding results—spontaneous delivery will occur, but that if there is no advance in a reasonable time Cæsarean section shall be performed, are often spoken of as "test cases." Everybody's experience is that most "test cases" finish up satisfactorily with little if any interference.

Apart from contraction of the pelvis, a routine examination of all, primigravidæ or multiparæ, should be made at about the thirty-sixth week, even if the pelvic measurements are normal. The presentation must then be ascertained and a malpresentation corrected if possible. In case of a breech presentation external version is often easy a month before term—much easier than at term or after labour has begun. All will agree with me that peace of mind and freedom from anxiety are important assets for a busy man. Most men of ripe experience with large midwifery practices say that they go to every midwifery case with a certain amount of anxiety. If the patient has not been seen before labour has begun it may be found at once that there is very real cause for anxiety. If, on the other hand, you examine all your patients, whether primigravidæ or not, at 36 weeks and again a few days before the expected date of labour, and satisfy yourself that all is well, you will give them a feeling of confidence and security and will reduce your own anxiety to the minimum. You will not care when labour starts, provided that it is not delayed more than a week or ten days after term, and it has no terrors for you, bar antepartum hæmorrhage and sudden eclampsia without warning—a rare occurrence. If the head is found to be well engaged, or deep in the pelvis, at the thirty-sixth week, there is no absolute need for an internal examination, but many men feel safer if they make an internal examination, in case there might be a small ovarian cyst in the pelvis. If there were, the head could not lie very deeply, but one cannot blame a man who likes to make certain and does not trust his abdominal examination implicitly. In a fat primigravida it may sometimes be impossible to say for certain that the head is in the pelvis when it has sunk unusually deeply—the head cannot be found, although everything points to a vertex presentation. Rectal examination is satisfactory in the case of a small ovarian cyst or a very deeply situated head. If you are not satisfied with your examination on account of excess of adipose tissue in the abdominal wall, or hydramnios, or multiple pregnancy, or rigidity of the abdominal muscles, never omit to examine under an anæsthetic and make certain.

### *Timely External Version.*

External version in cases of breech presentation in primigravidæ has been taught for many years, and recently external version in all cases of breech presentation has been advocated, especially by my colleague, Eardley Holland. I think that a good many men have been discouraged by failure because they have not attempted to perform external version until term or even just after the onset of labour. At that stage, especially in a primigravida, external version is often difficult and sometimes impossible, even under anæsthesia, while it is sometimes extraordinarily easy, and probably always possible, a few weeks before term. It is said that about 60 per cent. of all breech presentations undergo spontaneous version into vertex presentations between the thirty-fourth and thirty-sixth weeks, so it is unnecessary to interfere earlier than this. In a difficult case of external version with a breech presentation the trouble is that the breech cannot be displaced from the brim of the pelvis—when once it has been dislodged and pushed even a little to one side the rest of the manœuvre is simple. If the breech cannot be dislodged by abdominal pressure alone, two fingers, four fingers, or even the whole hand should be inserted into the vagina and the breech pushed up from below. The other hand of the operator then pushes the breech to one side while the anæsthetist or the nurse pushes the head to the opposite side. This may sometimes be done successfully even after some of the liquor amnii has escaped. Even if external version, before the onset of labour, has failed, it may be found, on examination some hours later, that the accoucheur's efforts have not been unavailing, and that the good work which he attempted had really been begun and that the movements of the fœtus and the shape of the uterus have succeeded in bringing about a complete version. I have seen this in two of my own cases. Prolonged attempts at external version in my consulting room, without an anæsthetic, had failed, and when I took an anæsthetist to the patient's house the next day I found that there was nothing to be done, the head now lying in the brim of the pelvis with the breech in the fundus. If external version fails before the onset of labour, the most likely reason for failure is that the legs are extended. When labour comes on this must be remembered, the feet sought for as soon as the membranes rupture, and if the legs are found to be extended, a foot brought down, before the breech has descended low enough in the pelvis to make this manœuvre difficult. At the East End Mothers' Lying-in Home last year, among 2179 patients, external version was performed before the onset of labour in 24 cases of breech presentation. All these 24 patients had normal deliveries.

It is important to remember that it is more difficult to diagnose the lie and presentation after labour has begun, especially after rupture of the membranes, and infinitely more difficult to correct abnormal lies and presentations then than in the last few weeks of pregnancy. A man who does not see his patients until they are in labour will get more than his share of difficult labours; he is handicapping himself, and is unjustifiably increasing the risks of mother and child. Public opinion is already beginning to influence men who have so far been inclined to look on antenatal investigations as a new-fangled fad, and it is certain that more and more patients will comment adversely on neglect of antenatal examination, just as some of them do if the urine has not been examined during pregnancy.

*Eclampsia.*—A very instructive result of antenatal supervision has been seen during the last few years. For the Fourth British Congress of Obstetrics and Gynæcology in 1923 a collective investigation was carried out into the results of various methods of treatment of eclampsia. After the meeting of the Congress the committee arranged that certain groups of hospitals should treat cases of eclampsia with various selected methods of treatment, in the hope that comparison of the results would furnish valuable information, but it was found that, although the project was taken up with enthusiasm, only very small numbers of cases of eclampsia presented themselves for treatment, antenatal supervision having made eclampsia a comparatively rare condition. It is such evidence as this that justifies the statement that midwifery is one of the most important branches of preventive medicine.

### *Abdominal Palpation.*

There are still some men practising midwifery who never make an abdominal examination during pregnancy or labour, probably because they, like myself, were taught nothing about abdominal palpation in pregnancy and labour when they were students. However expert they may be at vaginal examination they cannot distinguish between face presentation, breech presentation, and shoulder presentation before labour and early in labour, when the presenting part is high up, at the time when correction of a malpresentation would probably be easy. Consequently, it is by no means rare to find that a case has been treated as one of breech presentation for many hours until the appearance of a hand low down in the vagina forces on the attendant the diagnosis that the case is one of shoulder presentation. In some of these cases the fœtus is gripped by the uterus too firmly for internal version to be safe, and the only method of delivery is by decapitation. Abdominal examination in such a case, if necessary under anæsthesia, would have shown that the head was lying in one iliac fossa. I think that the term "transverse presentation," besides being a bad one, is a dangerous one, as it tends to the belief that the head lies low down on one side while the breech lies at the same level on the other side, and that the fundus does not reach up as high as usual. For this to be possible there must be a loose abdominal wall, a large amount of liquor amnii, and a small child, possibly dead. I have seen only one case in which a living fœtus, at term, lay really transversely. In the large majority of cases a so-called transverse presentation has only just missed being a first vertex presentation, obliquity of the uterus, or, much less often, contraction of the brim of the pelvis or obstruction due to a tumour having steered the head to one side of the middle line. Inspection of the abdomen or a perfunctory abdominal examination may not detect any gross deviation from the normal, the breech being at the fundus, very nearly in the middle line, but careful examination will show that the head is not in the middle line and that the fingers can be pressed down on the other side into the brim of the pelvis, which is not occupied by any large part of the fœtus.

Occipito-posterior positions provide a large proportion of cases of difficult labour, and there are still many men who consider that the only method of dealing with the difficulty caused by incomplete flexion of the head with failure of the occiput to rotate to the front, is to wait for a reasonable time and then pull with the forceps with sufficient vigour to overcome the obstruction caused by the passage of the larger diameter through the pelvis. There is still a great tendency to treat the injury to, or death of, the child and tearing of the mother's tissues as being a necessary result of the inherent difficulty of the case, a regrettable result, but not one for which the attendant need blame himself at all. This attitude of mind is due, largely, to the idea that manual rotation of the head when the occiput has remained behind is all very well to be put in text-books and lectures, but is not a manœuvre for practical men, and I am convinced, from conversation with many men in general practice, that there are large numbers of men in busy midwifery practice who have never even attempted manual rotation of the head. If they did attempt it they would find that in the large majority of cases they would be successful in converting a difficult case into an easy one, and that the mother would be saved from much unnecessary injury. In this condition as well something can be done in the way of prevention. The late Dr. Ballantyne, of Edinburgh, one of the chief pioneers in antenatal work, told me on the last occasion on which I met him, shortly before his death, that he had discovered a simple way, absolutely devoid of danger, of converting an occipito-posterior position into an occipito-anterior position before the onset of labour. He had found that a towel folded into a firm pad, pressed against the child's back, and kept in position by an abdominal binder, caused rotation of the child's body, with the head away from the pressure of the pad, so that what had been a third position of the vertex became converted into a left occipito-anterior position. Others have followed Dr. Ballantyne's teaching with success.

### *Premature Induction.*

Induction of premature labour in cases of a moderate degree of contraction of the pelvis or undue size of the fœtal head, and induction of labour in cases of post-maturity are valuable methods of preventing difficulties in labour. There is still a certain amount of difference of opinion as to the advisability of interference in cases in which labour does not come on at the expected time, but many men have a working rule that if the menstrual history and other data, especially the size of the child, leave little doubt that the calculated date is the correct one, it is best to terminate the pregnancy when ten days have elapsed with no sign of the onset of labour. The reason for making this rule is that if the onset of labour is delayed for three weeks or so there may be difficulty due to excessive ossification of the bones of the vault, and also that death during labour is liable to occur in cases of post-maturity, without obvious cause. At and after term induction of labour usually offers no difficulty, a dose of castor oil, or the castor oil, quinine, and hot-bath method nearly always being successful in starting labour. The same method may be followed by success three or four weeks before term, but, in my own experience, it often fails, and the method of induction of labour by insertion of bougies has to be adopted. Induction of premature labour is looked on with little approval by some, while others have the highest opinion of its usefulness. Personally, I have very often induced labour prematurely, and have never regretted having done so. Those who disapprove of induction of premature labour do so chiefly because they consider that the chances of the infant are small. This view is due to non-observance of two essential rules: (1) that labour must not be induced, for the sake of the baby, earlier than the thirty-fourth week, nor, if possible, before the thirty-sixth week; and (2) that, once the labour has started, delivery should be left to the natural forces, assistance with the forceps being avoided. There is an old superstition, dating from the time of Hippocrates, that seven months' babies live and eight months' babies die, and because of this absolutely erroneous idea labour has often been induced as early as the twenty-eight or thirtieth week with the result that the baby of 3 to 3½ lb. weight survives its birth only a short time. A baby born only four weeks early has as good a chance of survival as if it had been born at full-time. The head of a premature baby, being imperfectly ossified, will not stand pressure from the forceps which would be harmless to a full-time infant, and bipolar version after induction of premature labour is often fatal to the baby.

An objection often brought against the method of induction of premature labour by insertion of bougies is that it is uncertain or very slow. I have never been content with insertion of bougies alone, but have always added to it the method of separating the membranes round the internal os, taught, I believe, by Sir John Williams many years ago. An anæsthetic should always be given, as it makes asepsis much more easy of attainment. The anterior lip of the cervix is fixed by a blunt pair of forceps, such as ring forceps or ovum forceps, and the gloved forefinger, pushed through the cervical canal, separates the membranes all round the internal os as far as can be reached. After this three bougies are inserted. When this method is used in a parous woman the labour may be over in 24 hours, while in a primigravida labour has usually begun in 24 hours.

### *Patience.*

If one had been asked 25 years ago what were the essentials of successful midwifery one would have answered "asepsis and patience." To these must now be added antenatal supervision, but the other two remain as essential as before. To put as briefly as possible the difference between the conduct of labour in a lying-in ward and in general practice, one would say that in a lying-in ward the case is left to Nature as much as possible, and that the number of hours is considered of little importance as long as neither the mother nor the child shows signs of suffering from prolongation of the labour. If the pains are sluggish, or the head is large, or the pelvis is slightly contracted, or the pelvic floor is unusually strong, plenty of time is given for moulding to occur, and assistance is given only when the natural forces have proved themselves to be unable to effect delivery without aid. Labour lasting more than 24 hours is common in a lying-in ward, whereas in some practices it is a rare event. In private practice, on the other hand, the natural forces are not always given a fair chance, and artificial aid is given much sooner. The reasons for this comparative hurry are many. The friends and relatives, who may be present in force, are very much inclined to worry the doctor and to urge him to terminate the labour as soon as possible. The patient herself is very likely to beg the doctor to let her have chloroform and the forceps. The doctor is probably a busy man, with multifarious duties, and he cannot afford to spend long hours watching a natural process. With all these influences at work is it to be wondered at that "I think that I can get the forceps on now" is much more commonly heard than "I consider that she needs help with the forceps"? I may be told that I am old-fashioned, and also that I have no right to criticise the conduct of labour at which I was not present, but I am speaking from my own experience when I say that the midwifery forceps and pituitary extract have, in some practices, taken the place of patience. I have often had to operate, for ruptured perineum or prolapse, on patients who were said to have had a very difficult first labour, terminated by the forceps, although the labour from start to finish did not last 12 hours. In a multipara it may be fairly safe to deliver with the forceps as soon as the cervix has become fully dilated, but it cannot be safe to deliver a primigravida as soon as the forceps can be applied, as little if any moulding can have occurred, and no dilatation of the pelvic floor has taken place and the cervix is not yet fully dilated. In such a case damage must be done. The doctor has to pull hard, so he calls it a difficult labour, and the mother's tissues must be torn or stretched so quickly that they may never recover tone completely. I have seen many women who had had very difficult forceps deliveries in their first labours, so much so that they were told that they had pelvic contraction, and yet delivered themselves easily of 8½ or 9 lb. babies subsequently. I am certain that if the men who say that they always deliver with the forceps in a primigravida, if the head does not come down quickly after full dilatation of the cervix, would examine their patients afterwards they would be so much impressed by the evidence of tears of the cervix and vagina that they would alter their views and agree that the ideal time to apply the forceps in a primigravida is when the scalp is in sight. If it were possible to bring the head down half an inch or an inch not much harm would be done, but the trouble is that when the forceps is applied too soon the cervix still offers some resistance, and when the head does move it comes down with a run and the damage is done in an instant. These cases are what I referred to earlier as cases in which the difficulty is imaginary, not real, and they are responsible for a considerable proportion of the cases of difficult labour in some practices, in spite of the improvement in midwifery which has taken place.

### *Filling Up the Time.*

The doctrine of patience in midwifery is no new thing. Smellie, one of the founders of modern midwifery, who wrote 170 years ago, knew the value of patience and the importance of not letting his judgment be influenced by the patient's friends. Among his notes are to be read the following:

> "We prescribed a mixture to amuse the patient, and in about five hours she was safely delivered. . . . The membranes had been broke a long time. Finding the woman very uneasy and her friends importunate, I amused them (sic) with a palatable mixture of which I directed the patient to take two spoonfuls every half hour, my intention being to gain time."

Matthews Duncan, in 1870, wrote:

> "There is no obstetric doctrine more deeply impressed on all the valuable literature of our profession than this; that the mere duration of labour considered in itself and apart from other causes of danger likely to spring up as the process becomes protracted, is of little importance so far at least as the recovery of the mother is concerned. This doctrine is embodied in the ever-recurring inculcation of patience as the highest virtue of both mother and attendant in many and varied circumstances of distress during labour."

I will quote here some remarks that I made to students a few years ago, and apologise in advance if they are too elementary to be apposite.

> "Apart from the gross misdemeanours in the employment of the forceps—viz., attempts at extraction of the head before the dilatation of the cervix is complete, it is a common practice to deliver with the forceps, simply because labour is rather slow, because 'things are hanging fire'; in other words, because the busy doctor wants to get off to see some other patient or to go to bed. In some of these cases one is told afterwards that the delivery was very difficult indeed. The most comforting reflection that a doctor can make at the end of a difficult or tedious midwifery case is: 'Well, thank goodness, I have not done her any harm!' In such a case as that just mentioned—viz., the forceps being used simply and solely to expedite the labour, the doctor should ask himself: 'Can I do any harm by delivering with the forceps now?' If the patient is a primigravida and the scalp is not yet in sight, the honest answer must be: 'Yes, I may do some harm. I may stretch the pelvic floor too quickly or cause a tear.' A plan which I used to find useful in a case where I was bored with waiting and wanted to get away, was to make a vow that I would not even boil the forceps until at least two hours had gone by. In almost every case there was no need for the forceps to be boiled at the end of that time. It is foolish to be influenced by the anxiety of the relatives and to deliver with the forceps against your better judgment. It is much wiser to take the relatives into your confidence. Tell the mother and the husband that all is well, that you could deliver almost immediately if you thought it wise, but it would not be best for either the patient or the baby, and that it would be wiser to leave things to Nature. If you must leave the house, tell them that you have given a sedative and hope that the patient will get some rest, that when she wakes up the pains will be better, and that should the child come down rapidly and be born before your return, they need have no anxiety, as you have made certain that all is well and that the experienced nurse knows exactly what to do. You will nearly always find that relatives appreciate highly this taking them into your confidence, and rise to the occasion and agree that you are wise in being careful and leaving things to Nature."

### *An Example of Prevention.*

Some may think that the idea of preventing difficulties in labour on any large scale is Utopian, but I can bring forward proof that it is practicable. As an example of what antenatal supervision, asepsis, and patience will do in cases of delivery in the patients' own homes let me give the results of work in the district of the East End Mothers' Lying-in Home. In 1923, 1262 women were delivered. The forceps was used in 20 cases—i.e., under 1·6 per cent. There were three cases of morbidity in the puerperium and no death. In 1924 there were 1119 patients, 10 cases of forceps delivery—i.e., 0·9 per cent., 8 cases of morbidity, and no death. In 1925, 1092 cases were attended. There were 22 cases of forceps delivery—i.e., 2 per cent., chiefly in tired multiparæ. The average weight of the babies delivered with the forceps was 9 lb. There were two deaths in the 1092 cases, one from acute hæmorrhagic pancreatitis and the other a case of sudden death in a very fat woman with fatty degeneration of the heart, immediately after a spontaneous labour.

I emphasise the results in this district because the East End Mothers' Lying-in Home is run by general practitioners. There is a large consulting staff, but the position of consultant to the Home is almost entirely honorary. I am practically the only member of the consulting staff who is ever called in, and I have been asked to see patients there about ten times in the last 20 years. I am claiming no credit for the figures which I have quoted.

I have hardly touched on the conduct of difficult cases, but I do not regret this, as I consider that their prevention is a more important subject. I have said a good deal about ideals. We must all recognise, with regret, that in our practice we cannot always attain to our ideals, but as we are all discontented with the present results of midwifery we must do what we can towards better results in the future, and can do this only if we have an ideal at which to aim.

---

## ON THE USE OF
## SILVER FILIGREE IN INGUINAL HERNIA.

BY PERCIVAL P. COLE, F.R.C.S. ENG.,
SENIOR SURGEON AND LECTURER ON OPERATIVE SURGERY, SEAMEN'S HOSPITAL, GREENWICH.

SOME time ago in THE LANCET[1] an attempt was made to defend the use of filigree against an attack supported, as I tried to show, by evidence either inadequate or irrelevant. I was not at that time in a position to press its claims otherwise than by the expression of a firm personal conviction and by brief histories of a few rather recent cases. To test the value of the method by the results obtained, an impartial inquiry has been instituted based on the records of the Seamen's Hospital.

The following figures show the number of herniæ dealt with by the filigree method from 1910.

1910, 21; 1911, 22; 1912, 25; 1913, 57; 1914, 24; 1915, 9; 1916, 26; 1917, 35; 1918, 23; 1919, 9; 1920, 20; 1921, 11; 1922, 10; 1923, 21; 1924, 35; total for 15 years, 348.

Table I. shows percentage relation to total operations during the last five years. The lower incidence in years 1915 and 1919 is due to conditions determined

TABLE I.—*Total Number of Herniæ Operated on at the Seamen's Hospital, 1920–24.*

| Year. | Total. | Filigree operations. |
|---|---|---|
| 1920 .. .. .. | 95 | 20 (20 %) |
| 1921 .. .. .. | 130 | 11 (8·5 %) |
| 1922 .. .. .. | 131 | 10 (8 %) |
| 1923 .. .. .. | 152 | 21 (14 %) |
| 1924 .. .. .. | 155 | 35 (22·5 %) |
| Total for 5 years | 663 | 97 (14·5 %) |

by the beginning and ending of the war. The diminished use in 1921 is explained by the retirement from the staff of Mr. L. McGavin, the protagonist and introducer of the filigree in this country. It is significant that a staff foreign to the filigree tradition and uninfluenced by the enthusiasm and example of its most ardent advocate, should have adopted the method with increasing frequency, as shown by the figures for 1922, 1923, and 1924. This independent testimony, based solely on personal experience, is surely noteworthy.

Records of personal experience show that I have used filigree in 60 cases of inguinal hernia at the Seamen's Hospital, and that I have never had occasion to remove a filigree from any one of my own cases or those of my colleagues past or present. The possible suggestion that filigree is used without discrimination is negatived by the fact that the relation of filigree to total operations in my series has varied in different years from 11 to 30 per cent., and that my total of filigree operations is constituted as follows: 75 per cent. direct or large scrotal; 12 per cent. recurrent; 13 per cent. oblique with unduly deficient musculature. As a further check on general and personal experience evidence as to remote results has been collected by means of a form of questionnaire sent out to 50 cases dating back to 1910. The cases were selected impartially, except that preference was given to those that appeared from details of address, &c. to be more likely to be traced.

The form of questionnaire was as follows:—

1. Did the wound break down or cause any trouble after you were discharged from hospital?
2. Have you noticed any swelling in the wound?
3. Have you had any pain in the wound? If so, for how long? Have you any pain now?
4. What is your present occupation?
5. Does the wound interfere in any way with your work? If so, how?

Twenty replies were received, a satisfactory number in view of the shifting nature of a seafaring population.

TABLE II.—*Present Condition of 20 Patients with Filigrees.*

| Year. | No. of case. | Operation and No. of filigrees used. | Comments. | Present occupation. |
|---|---|---|---|---|
| 1910 | 1 | Double I.H. (F.4). | Slight discomfort at times. Other A.N.* | Seaman. |
| 1911 | 2 | I.H. ? side (F.2). | All A.N. | Lighterman. |
| | 3 | " | " | Motor-driver |
| 1913 | 4 | L.I.H. (F.2). | Slight pain occasionally. Other A.N. | Labourer. |
| 1915 | 5 | Recur. I.H. (F.2). | All A.N. | Labourer's assistant. |
| 1917 | 6 | Double I.H. (F.4). | " | Labourer. |
| | 7 | R.I.H. (F.2). | Occasional tenderness. Other A.N. | Dock labourer. |
| | 8 | Recur. I.H. (F.1). | All A.N. | Lighterman. |
| | 9 | Recur. (F.2). | Occasional pain on standing. Other A.N. | Waterman. |
| 1918 | 10 | Double I.H. (F.4). | All A.N. | Engineer. |
| | 11 | Strang. I.H. (F.2). | " | Labourer. |
| 1919 | 12 | Double I.H. (F.3). | " | Messenger. |
| | 13 | R.I.H. (F.1). | " | Labourer. |
| | 14 | L.I.H. (F.1). | " | Marine engineer. |
| 1920 | 15 | R.I.H. (F.1). | " | Ship's cook. |
| | 16 | " | Slight swelling. Brooks appliance. Other A.N. | Ship's steward. |
| 1921 | 17 | " | All A.N. | Seaman. |
| 1922 | 18 | R.I.H. (F.2). | " | Fireman. |
| | 19 | L.I.H. (F.1). | " | Warehouseman. |
| | 20 | R.I.H. | " | Seaman. |

* It will be noted that as regards the condition of the operation area negative answers (A.N.) indicate satisfactory results.

The results are indicated in Table II. All the operations, with two exceptions. were performed either by Mr. McGavin or myself. Of these 20, 15 cases have absolutely nothing untoward to report. They have remained cured for periods varying from 3–15 years, and are still engaged for the most part in laborious occupations. Four cases complain of occasional pain or tenderness, but this has in no case interfered with their work. Doubt as to cure arises only in one case. This patient, a ship's steward, reports slight swelling, and is wearing a Brooks appliance. The patient says he noticed the swelling immediately after the operation, and that it has not increased in size in the five years that have elapsed since operation. He is still engaged as a ship's steward, an occupation entailing a good deal of heavy lifting

---

[1] THE LANCET, 1924, i., 385.

Results such as these, particularly in view of the class of patient concerned, and the laborious occupations pursued by them cannot, I think, be excelled—if, indeed, they can be equalled—by any other method. A further convincing testimony to the merits of the method is afforded by the fact that during the last four years four of my professional colleagues at the Seamen's Hospital have submitted themselves to filigree implantation

# TOXIC (SUBDURAL) MENINGEAL HÆMORRHAGE.

BY A. G. BANKS, M.D. GLASG., F.R.C.S. EDIN.,
SURGEON, EAST SUFFOLK AND IPSWICH HOSPITAL,
AND
A. M. N. PRINGLE, M.B. EDIN., D.P.H. CAMB.,
MEDICAL OFFICER OF HEALTH, IPSWICH.

MENINGEAL hæmorrhages are known to occur in the course of the specific infectious fevers, in purpura, tuberculous and other forms of meningitis, and heat-stroke. They may occur spontaneously in young females without previous disease at the menstrual periods. Such hæmorrhages are, however, only complications, and their presence is seldom manifested by definite clinical signs, or at least is overshadowed by the original disease

There appears to us, however, to be another fairly well-defined clinical type, the chief characteristics of which are spontaneous bleeding without recognisable previous disease—meningeal signs mainly irritative—short duration of attack, and complete recovery following lumbar puncture The fluid withdrawn by puncture varies from a mere coloration to practically pure blood and is always sterile on cultivation.

We have met with three such cases within the last few years, and are inclined to believe the condition more common than the number of the recorded cases would indicate

### *The Cases Described.*

CASE 1.—M. B., a girl of 13, was seen on Sept. 29th, 1925, complaining of severe headache and pain in the right chest, onset sudden, she having been quite well the previous day There was great prostration, temperature 104° F., pulse 120 A pleuritic rub was detected in the left lower axillary region, although no symptoms were referred here.

30th: Headache more intense, diffused, and continuous during the night. Pain complained of in the sternal and præcordial areas. Temperature 101.5°, pulse 130 Slight nuchal rigidity and tenderness observed Knee-jerks sluggish and easily exhausted A quite definite pleuro-pericardial rub was present just inside the apex. The urine contained a considerable quantity of albumin.

Oct. 1st: Headache severe and persistent, tongue dry and furred, pupils widely dilated, equal and active. No pain in chest, pleuro-pericardial friction gone, but apex beat 1 in. outside nipple line and a soft systolic bruit present Neck stiffer and more painful on movement, with pressure pain over the cervical vertebræ and lateral neck muscles, extending as far as the shoulders. Temperature and pulse as before Kernig's sign indefinite, knee-jerks abolished, and superficial reflexes hardly obtainable Tache cérébrale present. Babinski's reflex plantar.

2nd: General condition considerably worse, patient looking very ill and complaining bitterly of headache; has vomited once. Tongue very heavily furred. Marked photophobia. Pupils as before. Kernig definitely positive and slight movements of the head very painful. Under light anæsthesia lumbar puncture was done and about 15 c.cm. of blood withdrawn under some tension. By evening the temperature had fallen to 100°, pulse 110, no headache since recovering from anæsthetic. Kernig still positive, but cervical signs much less acute.

3rd: Patient slept all night and declared she felt quite well. Temperature normal, pulse 80, tongue nearly clean, no headache nor rigidity of neck, only slight tenderness on pressure Kernig negative. Knee-jerks still absent Appetite returning. In two days the knee reflexes had become brisk, the heart normal, and recovery seemed complete. Examination of the fluid withdrawn showed it to be practically pure blood; no cerebro-spinal fluid could be separated; sterile on culture.

Two points in the previous history were under consideration: 1 Some years ago the patient was under the care of one of us (A. M. N. P.) with a suspicion of T.B. lung, but nothing definite was found after careful clinical and radiological investigation. 2 For some four or five week-ends previous to this illness she had attacks of intense coryza with great malaise, lasting about two days On Sept. 28th, 1925, she was perfectly well. Recently her father has also suffered from the same kind of attack.

Two similar cases came under the notice of one of us (A. M. N. P.) during the prevalence of cerebro-spinal fever some years ago.

CASE 2.—E. H., female, aged 31. Admitted to the isolation hospital with symptoms suggestive of meningitis, very sudden onset, headache, vomiting, pain and stiffness in the back of the neck, rigidity of the spine, rise of temperature, and general malaise. Lumbar puncture gave a homogeneous mixture of blood and cerebro-spinal fluid. The fluid was sterile. The case was diagnosed as one of meningeal hæmorrhage Recovery was rapid and uninterrupted, the whole of the symptoms disappearing within a day or two.

CASE 3.—H. O., male, aged 42. Admitted to the isolation hospital as a possible case of cerebro-spinal fever The symptoms were similar to the above. Lumbar puncture revealed the same homogeneous mixture of blood and cerebro-spinal fluid. The fluid was sterile Immediate improvement followed the relief of tension and the patient made a complete recovery.

### *Cases Recorded in the Literature*

The condition is hardly mentioned in the standard English works on general medicine or in those dealing specially with diseases of the brain and spinal cord. Branson[1] records two cases—probably influenzal, with bloody fluid withdrawn under considerable pressure by lumbar puncture; the spinal symptoms were slight and followed by complete recovery. Emile-Weil, Isch-Wall et Pollet[2] report a case of pure meningeal hæmorrhage in a woman, with symptoms of mild cervical irritation and rise of temperature and which recovered in a few days after puncture The cerebro-spinal fluid was blood-stained. This patient (among others) showed delayed coagulation of the blood and they stress this as a factor in these hæmorrhages Raymond[3] draws attention to the early and abundant albuminuria in this condition and notes exaggeration of the reflexes here as contrasted with cerebro-spinal fever. One may infer that he writes from personal knowledge of this condition, though we cannot find that he has published any cases.

In our first case the quantity of albumin in the urine on the second day was remarkable, but the reflexes were depressed or absent. At the time of puncture the blood showed a normal coagulation time. The hæmorrhage would appear to have been the result of some general infection, as witness the cardiac and pleural signs, probably an influenzal, intestinal, or naso-pharyngeal toxæmia.

Meningeal hæmorrhage may closely simulate encephalitis lethargica, the diagnosis being established only on lumbar puncture. Rathery et Bonnard[4] give a very full report of such a case in a girl of 18, with severe headache, vomiting, rigidity of neck, positive Kernig, and complete somnolence—all of sudden onset and no history of previous disease Lumbar puncture revealed a cerebro-spinal fluid, frankly red throughout and sterile in culture. There was a marked polynuclear leucocytosis (33,000). The stupor gradually cleared up under repeated punctures and she was well in a month. A rat inoculated with the cerebro-spinal fluid reacted but did not succumb. Flessinger et Janet[5] record a fatal case of meningeal hæmorrhage, with an even greater similarity to encephalitis lethargica

A woman aged 40, apparently in good health, was suddenly affected with loss of consciousness, intense headache, and rigidity of neck; a positive Kernig was present and some fever Somnolence and stupor supervened and persisted till death, a month later; there was also hemiplegia and later other paralyses. The spinal fluid was at first uniformly mixed with blood, the colour becoming less toward the end of her illness. Careful histological examination of the brain showed no trace of perivascular congestion nor inflammatory reaction; inoculation of a rabbit with an extract of brain and spinal fluid, according to Levaditi's technique, had no effect on the animal's health.

Otero[6] records two cases of meningeal hæmorrhage following a wave of epidemic encephalitis, the symptoms of which were: sudden and severe headache and loss of consciousness. The condition persisted for several days and recurred in one case five to six months later. In both complete recovery followed lumbar puncture, which was done six times in the first and three times in the second case. The cerebro-spinal fluid was sterile.

The association of cases of meningeal hæmorrhage with epidemic encephalitis or cerebro-spinal fever is probably accidental; there is no evidence whatever of any ætiological relationship. Although these latter cases are more severe than the former, and in spite of the occurrence of stupor (and in one case of paralysis), we think they belong to the same group and have a similar ætiology. It will be noted that only one case in the whole series died. The disease may therefore be considered a comparatively benign one. Furthermore, there does not appear to be any definite relationship between the quantity of blood present on puncture and the severity of the disease, thus lending support to the toxic nature of these cases.

# Clinical and Laboratory Notes.

## TWO CASES OF PUERPERAL FEVER.

By ROBERT SWYER, M.R.C.S. ENG., D.P.H.,

SENIOR ASSISTANT MEDICAL OFFICER, NORTH-WESTERN HOSPITAL.

THE cases here recorded present interesting and unusual features.

CASE 1. *Thrombosis of the Inferior Vena Cava.*—The patient was a multipara aged 42, with ten children all living. She was confined on Nov. 15th, 1924, and admitted to the North-Western Hospital a week later, certified as puerperal fever. It had been a breech presentation, the labour lasting five hours and being followed by retention of the placenta, which was removed manually by her medical attendant after a further period of two and a half hours. The temperature was said to have been raised ever since confinement.

*Condition on Admission.*—Temperature 99° F., pulse 100, and respirations 24. Uterus firm and 2¼ inches below umbilicus, lochia scanty and not offensive; slight tenderness in the right iliac fossa. She was treated with hot vaginal douches of lysol solution four-hourly, and mist. mag. sulph. co. mane et nocte. For a week the temperature continued to swing between 98° and 101° and the pulse-rate between 100 and 140. In spite of this her general condition appeared to be improving until the night of Nov. 26th, when she had a slight rigor, followed by two more during the next night. On the 29th I introduced a catheter into the uterus and injected 10 c.cm. of sterile glycerine; during this procedure much foul brownish discharge issued from the os uteri. The catheter was left in situ for six hours, the patient being propped up in bed. During the next day she appeared better until 10 P.M., when the temperature rose to 105°. The injection of glycerine was repeated on Dec. 1st and 4th when a considerable amount of yellowish pus escaped from the uterus. Bimanual examination revealed an indurated cord outside the right vaginal wall running up to the right lateral fornix. It was not tender.

On Dec. 7th there was pain and swelling of the left leg which increased until the 13th. Rigors occurred on Dec. 3rd, 4th, and 13th, the last one accompanied by air-hunger and a very rapid, fluttering pulse. Breathing was rapid and laboured during the 14th but improved next day, as did also the heart. Further rigors occurred on the 16th and 18th. From Dec. 13th the swelling of the left leg diminished until on the 29th it was practically normal, but on this day the right became swollen. On Jan. 3rd, 1925, hæmorrhages appeared in the skin of the right leg. On Jan. 9th the patient said she did not feel so well although she had had a good night. At 8.15 A.M. she suddenly became very pale and cyanosed, but did not complain. The cyanosis lasted about half an hour and was followed by blanching, and at 9.20 A.M. she looked moribund. She died at 1.45 P.M. the same day.

*Post-mortem Examination.*—There were many hæmorrhages into the skin of the right leg, which was œdematous and about half as large again as the left. The brain was normal. A small quantity of turbid fluid and a few recent fibrous adhesions were present in the left pleural cavity. Patches of broncho-pneumonia and pyæmic abscesses were present in both lungs, the left being much more affected than the right. At one of the secondary branchings of the right pulmonary artery a small whitish embolus was lodged. The heart and coronary arteries appeared normal. The uterus was well involuted and empty. There was some thickening of the right broad ligament which was probably a partly resolved parametritis. The right internal iliac vein and inferior vena cava were filled with a suppurating blood-clot. A dark red fairly firm clot extended down the right femoral vein and a similar clot filled the left common iliac and femoral veins down into the leg. The spleen was much enlarged and very friable. The right kidney was larger and paler than the left. About 50 small gall-stones were found in the gall-bladder. The remaining organs appeared normal.

A striking feature of the case was the persistently high pulse-rate even during apyrexial periods, varying between 92 and 140 with an average of about 116. Except when rigors were occurring pyrexia was not marked; indeed, there were periods of several days when temperature did not rise above 99°.

CASE 2. *Recovery after Severe Puerperal Septicæmia.*—The patient, aged 37, was admitted to the North-Western Hospital on Sept. 24th, 1925, with the following history. On July 23rd of that year she had an incomplete abortion, the placenta being retained. The period of gestation was about three months. She did not go to bed but went about as usual and felt well until Sept. 13th, when she had abdominal pain and a "flooding." Two days later the placenta came away. On the 21st she had general pains, delirium, and sleeplessness. Dyspnœa was present on the 22nd.

*Condition on Admission.*—She looked extremely ill. The breath was fœtid, tongue dry and covered with brown fur. Temperature 103° F., pulse 110, respirations 38. There were signs of bronchitis in both lungs but no consolidation. The heart sounds were normal. There were no signs of laceration of perineum or vagina. Bimanually the uterus seemed a little enlarged but was freely movable. No tenderness was present in the vaginal vault, but I could feel a slight induration extending laterally from the cervix on the right side. There was no uterine or vaginal discharge. A small indurated swelling was present on the inner aspect of the right thigh. She remained drowsy and delirious until Sept. 26th when she was seen by Dr. L. Colebrook, of St. Mary's Hospital. He and I then believed her to be dying. A blood culture was made which showed a hæmolytic streptococcus. The number of organisms was 300 per c.cm. The following day an inflammatory swelling appeared on the right forearm. On the 28th a superficial pustule appeared on the right knee. On Oct. 2nd the abscess on the right thigh was opened and drained. At this time she complained of pain in the right shoulder and upper arm. On the 5th the abscess had ceased to discharge but another small abscess appeared above it accompanied by induration of the right labium majus. The pain in the right arm had become more severe but no physical signs could be detected. On the 8th the temperature, which up till then had been swinging between 104° and 97°, became normal, and remained so until her discharge from hospital.

On the 13th there was definite wasting of the muscles of the right hand with marked weakness of grip. Marked dryness and hardening of the skin on tip of thumb and first finger was noticeable. The paralysis rapidly increased until three days later the right arm was completely paralysed and flaccid. There were no sensory changes. On the 28th another abscess developed over the middle third of the right thigh; by this time power was beginning to return to the right arm and the pain was much less severe. The abscess was opened on Nov. 7th and had healed by the 18th. On Nov. 22nd a painful swelling appeared at the junction of the right fourth rib with the costal cartilage.

By Nov. 30th the general condition had so far improved that she was allowed to sit up in a chair, and ten days later got up in clothes. During this time the swelling on the chest had been gradually increasing in size but was not very *ender and never became soft*; a few days later it began o diminish and eventually disappeared. The paralysis of he arm had practically disappeared by Feb. 2nd, 1926, when the patient was discharged from hospital.

I have never before heard of a case recovering after so severe an infection of the blood with a hæmolytic streptococcus and having all the local esions confined to the right side of the body. She had no injections or inoculations of any kind while in hospital.

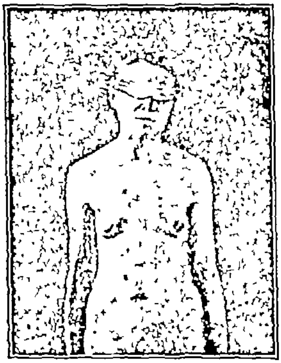
## WIDESPREAD SECONDARY GROWTHS FROM VULVAL CANCER.

By A. E. CHISHOLM, F.R.C.S. EDIN.,
ASSISTANT TO GYNÆCOLOGICAL AND OBSTETRICAL DEPARTMENT, ROYAL INFIRMARY, DUNDEE.

THE following case, showing a quite unusual spread of cancer, seems to be worthy of record.

The patient, a woman of 43, was admitted to the gynæcological department of Dundee Royal Infirmary on April 5th, 1924. She had had six children, the last one born two years previously. She had noticed a wart-like growth on the left labium for upwards of a year, and for ten months it had caused severe pain at times. As time went on it increased in size, ulcerated, and became more painful.

The nodule was situated towards the anterior end of the left labium minus. It was hard, ulcerated, and mobile. There was no induration round about it. The glands in the left groin were moderately enlarged. Those in the right groin were rather more palpable than normal. The patient was not emaciated. No other secondary growths were found.



Photograph taken in October, 1924, showing nodules on abdomen, chest, and neck.

On April 15th, 1924, I excised the tumour along with the left labium minus and dissected out the glands of the left groin. The pathological report on the tumour and glands indicated flat-celled epithelioma. The patient was discharged from hospital on May 17th, 1924.

I had the opportunity of making a later examination in October, 1924. There was definite emaciation, but no recurrence of disease in the vulva, and a per vaginam examination revealed nothing abnormal. A very small subcutaneous nodule could be felt just below the outer limit of the left inguinal scar. The glands in the right groin were markedly enlarged. Dozens of discrete, subcutaneous, mobile nodules, of varying sizes, could be seen or felt over the front, back, and sides of the abdomen and chest. The axillary glands were enlarged, as also those of the right anterior triangle of the neck and of both posterior triangles. There was a nodule just in front of the left masseter and one above the left eyebrow. On Nov. 11th, 1924, I visited the patient in her house. She was looking very ill and had a good deal of pain in the back. The movements of the lumbar spine were pretty good. There was no evidence of involvement of internal organs. The subcutaneous nodules showed evidence of growth since the last examination and some of them were taking on a livid appearance. The nodules on the anterior abdominal wall were innumerable.

The patient died on Jan. 6th, 1925. I did not wish to trouble her, in her weak state, by taking away a nodule under local anæsthesia for microscopic examination, and I did not hear of her death for some time after its occurrence, but there can be no doubt that the nodules were cancerous, secondary to, and of the same nature as, the original vulval tumour.

Vulval cancer is frequently peculiarly fatal, and any suspicion of such a condition being present should be investigated as soon as found. The accompanying photograph gives a very poor idea of the actual condition. Properly to estimate the multiplicity of the nodules, the sense of touch was required.

I am indebted to Prof. J. A. Kynoch for permission to publish the case.

## ROYAL SOCIETY OF MEDICINE.

### SECTION OF OPHTHALMOLOGY.

A MEETING of this Section was held on May 14th, Sir ARNOLD LAWSON, the President, occupying the chair.

### *Black-spot Choroiditis.*

Mr. RAYNER D. BATTEN gave a demonstration of drawings—shown by means of the epidiascope—illustrating, first, black-spot choroiditis, secondly, a special form of senile retino-choroidal atrophy of the macula. Black-spot choroiditis, he said, was a fundus disease which had not received due attention from either the clinician or the pathologist. It occurred in association with myopia, but was not peculiar to it, occurring, as it did sometimes, in people with hypermetropia. It was not confined to the macula, but he considered it was limited to the central area, that embraced by the superior and inferior temporal vessels. He recognised three forms of black-spot choroiditis. The generally recognised form was found, usually, in high myopia. In this the onset was acute, the process coming on with dramatic suddenness. There might be an accompanying hæmorrhage, but in his experience hæmorrhage had never been a marked feature. He showed a number of slides illustrative of this condition, and gave a brief account of the ophthalmic history of each patient. In another form of the condition the onset was not quite so acute, and the area of choroidal atrophy, after it had been formed, tended to get smaller, and the eye might regain some useful vision. In some of these patients there was seen first a blurred, œdematous area, without any black spot being visible. Later a black spot appeared, a diffuse hæmorrhage, with an area of atrophy around it. In yet another group a black spot was seen, but loss of vision was not a necessary accompaniment. Mr. Batten showed a number of slides of these.

### *Senile Retino-choroidal Atrophy.*

Mr. Batten's last series were of a definite class of macular disease or degeneration in old people, which did not seem to have received much study as a group. In the first few cases of the kind which he saw the patients gave evidence of mental or cerebral disturbance, but the view of physicians had not supported his idea that mental deterioration was a necessary accompaniment. These patients all had arteriosclerosis, however, and there seemed to be nothing else from which they suffered. The ophthalmoscopic picture presented by them warranted their being placed in a distinct class. The retino-choroidal condition was of slow formation and long duration, and it was markedly symmetrical in the two eyes. The superficial layers of the choroid were wanting, leaving the choroidal vessels running across the base. The margins showed retinal changes, with that fine pigment loss which he regarded as evidence of retinal disease.

The PRESIDENT said three of the pictures shown were of his own patients. In two of them the cause was certainly inflammatory, and the patients had severe pyorrhœa. Clearance of the mouth caused the process to stop, but improvement of vision could not be expected owing to the loss of tissue. He had always regarded the formation of pigment as a sign of inflammation rather than of hæmorrhage. He did not regard myopia as causally connected with the changes shown in the first group of drawings.

Mr. J. H. FISHER said it was recognised that the nutrition of the retina at the macula was a matter of supreme importance to the vision of the eye, and with that object the capillary network was more dense and efficient in that situation than in any other part of the choroid coat. The pigmentation which was present in the cases Mr. Batten demonstrated was, presumably, the result of imperfect nutrition. In the arterio-sclerotic group of cases there was an atrophy of the chorio-capillaris which was conspicuous over the central area, with an accumulation of pigment at the periphery, and but little pigment where the chorio-capillaris was obviously deficient. In the myopic cases, however, there was an area of choroidal atrophy, forming a kind of framework, and in the centre of that area was found an accumulation of pigment. In seeking for an explanation of the difference in the two classes of cases, it occurred to him that in the arterio-sclerotic cases there was obstruction of a branch of the artery which conveyed the blood to the chorio-capillaris in the situation of the macula, except at the periphery, and at the periphery the circulation was probably at a low ebb, hence in these cases there would be but very little nutrition of the pigment layer at all. In highly myopic eyes there was a considerable tendency for fissures to occur in the choroid coat, so that choroidal rupture was not unlikely. He thought an explanation on these lines would cover the main differences between the two classes of cases which Mr. Batten had discussed and illustrated.

Mr. E. TREACHER COLLINS said he had seen cases of black spot in the retina, and he believed the general view was that they were due to hæmorrhage. He had seen at an early stage what looked very much like hæmorrhage become a black spot. This bleeding was most probably from choroidal, not from retinal, vessels, and that was one reason why the pigmentation was so dense. The mere fact of a sudden onset strongly suggested hæmorrhage. It was one of the complications which were liable to occur in highly myopic eyes. The immediate result was a loss of central vision. He had watched patients with this condition for several years, but had never seen detachment of retina occur in them. Patients could be assured that they would not lose more than their central vision, though restoration of the vision they had lost could not be expected.

Mr. H. R. JEREMY thought some of the cases described must be due to hæmorrhage, especially in high myopes. He referred to the case of a boy, aged 17, whose myopia was −15 in one eye, −19 in the other. He was already blind in one eye, and while at a dance he suddenly lost the sight of the other. He had a black spot in one eye, and in the other a large hæmorrhage below the macula. The speaker ordered him to bed for six weeks, at the end of which time he had recovered sufficient vision to enable him to get about.

Mr. J. F. CUNNINGHAM described the appearances in a myope who was under his care. In 1910 she had 6/9 vision, and the myopia was −10, and in that eye she rapidly developed coal-black spots, and in one eye there was a circular-shaped retinal detachment. Since the war there had developed in the situation of the black spot a large area of choroidal atrophy, with sclerosis of vessels.

## SECTION OF OTOLOGY.

A MEETING of this Section was held on May 8th, Mr. G. J. JENKINS, the President, in the chair.

The PRESIDENT and Sir STCLAIR THOMSON (President of the Society) referred to the death of Prof. Bradenego, of Naples, whom Sir StClair Thomson described as one of the pioneers of the renascence of otology. A vote of condolence was passed.

### *Mosher's Method of Skin Grafting.*

Mr. LIONEL COLLEDGE gave a description of Mosher's method, which he regarded as very satisfactory. The trouble with moulds and stents, he said, was that a mould was solid, and if a solid mould of a cavity were made in order to cover it with a graft, it would be necessary to reopen the cavity so as to remove the mould. Dr. Mosher stated that he had been using the method for ten years and had found it satisfactory. Strips of gauze which had been soaked in paraffin wax were folded so as to form a cone. Having got the cavity ready, a hollow mould of this gauze was formed. The gauze was softened by putting it into warm water, and then the Thiersch graft was wrapped round it. A satisfactory adhesion resulted, and there was no irritation or sepsis even when the graft was left in position for seven or ten days. It could be very accurately applied, and later the mould could be removed without disturbing the graft.

### *Unusual Case of Acute Mastoiditis.*

Mr. JEFFERSON FAULDER showed a boy, aged 10, whose condition, following a complete mastoid operation in February, 1925, gave rise to much anxiety. There had been a history of earache every spring, with recovery each time until the present illness. In childhood the boy had suffered from pneumonia and hip disease. At the operation Mr. Faulder discovered osteomyelitis of the whole right mastoid process. Before operation the temperature was 102° F.; on the next day it was 105°, and pyrexia continued thereafter, with occasional remissions, for six weeks. There was extreme tenderness over the whole right sterno-mastoid muscle for a week, and slight pain over the left lower chest for the first week. During the whole time the respiration rate was 32 to 24. In the fifth week dullness was noted at the right base, and X rays revealed a dull patch there. At the beginning of the sixth week the patient suddenly coughed up 4 oz. of pus, and thenceforward recovery was rapid. Mr. Faulder said that if he had yielded to the temptation to reinvestigate the lateral sinus and jugular vein and had done so successfully, the cure would probably have been attributed to that procedure. An X ray examination at an earlier stage might have helped the diagnosis. It was suggested that in both lungs there was a weak area, and that one of these was affected by inhalation so as to cause an abscess.

### *Sequestrum of Semicircular Canals.*

Dr. MACDONALD showed a woman, aged 41, on whom the radical mastoid operation was done on the left side in 1921. At that time there was complete loss of hearing, giddiness, and slight horizontal nystagmus to the left. Granulations were present in the antrum, and there was an extensive destruction of ossicles. The discharge from the ear was continuous, and in 1925 the patient had vertigo and left facial paralysis. In March last she was readmitted with left facial paralysis and horizontal nystagmus to the right, complete deafness on the left side, and loss of labyrinth responses on that side. The Wassermann was negative. A sequestrum was removed from the semicircular canals, and the posterior wound was closed by means of a sliding flap.

Other cases were also shown.

---

# ROYAL ACADEMY OF MEDICINE IN IRELAND.

## SECTION OF MEDICINE.

A MEETING of this Section was held on April 23rd, Dr. F. C. PURSER, the President, in the chair.

### *Scleroderma.*

Dr. KATHLEEN LYNN showed a case of scleroderma in a child aged 7 months. Scleroderma, she said, generally attacked infants when they were only a few days old, and they usually died in a short time. This infant had been perfectly normal until it was 2 months old, when symptoms became well marked. Recently there seemed to have been some improvement.

Dr. M. DRUMMOND said that the case was in some respects almost unique. Generalised scleroderma was very unusual; he had only seen two cases, one of which had died at 2 months and the other at 5 months.

Dr. W. G. HARVEY congratulated Dr. Lynn on keeping the child alive for so long He had seen a few similar cases, but never one that had done so well as this.

The PRESIDENT said that the case was very interesting and uncommon. He had seen the infant three days previously, and had been told that it was improving almost daily, but although it was certainly no worse he did not think it had improved.

Dr. LYNN, in replying, said that there was apparently no specific history in the family. The father had recovered from tuberculosis; of nine children one was an idiot, three were still alive, and six dead. In scleroderma the temperature was usually raised, but this infant's temperature was always subnormal. There had been no gain in weight, but she thought the child had improved a little; on some days it was better, and on others it was worse.

Dr. DRUMMOND showed a case of Tuberculide of the Skin simulating Leprosy; Dr. HARVEY showed a case of Alkaptonuria; Dr. L. ABRAHAMSON showed a case of Syphilitic Disease of Bone simulating Rheumatoid Arthritis; and Dr. G. E. NESBITT showed electrocardiograms illustrating Ventricular Tachycardia and Left Bundle Branch Heart-block.

Dr. GEOFFREY BEWLEY read notes on two cases of

### *General Paresis treated with Malaria.*

Both cases had a fully positive Wassermann for 0·1 c.cm. of cerebro-spinal fluid, a cell count of about 50 per c.mm., and a strongly positive colloidal gold curve. In each case the rigors occurred every evening and were controlled, after ten had occurred, by the exhibition of quinine. In the first case the mental change was dramatic, the patient becoming perfectly normal in a fortnight and being discharged from the asylum six weeks after treatment, when the Wassermann had become negative for 0·1 c.cm., the cell count almost normal, and the colloidal gold curve a very weak paretic. Four weeks after being discharged, however, this patient had had an acute melancholic attack which necessitated re-certification. In the second case three weeks after treatment the Wassermann had dropped to plus 1 for 0·1 c.cm., and the cell count practically to normal, but the colloidal gold curve remained unchanged The mental condition had slightly but steadily improved.

The PRESIDENT said that the clinical results in these two cases seemed quite as good as any he had seen reported. The pathological results in the first case were very good and made him think that this treatment was of more permanent value than was thought by many who had tried it.

Dr. H. T. BEWLEY said that he had seen these cases frequently, and the first case was a typical case of G.P.I. from the mental point of view. The recovery was the most dramatic thing in mental medicine that he had ever seen. The second illness of the patient was very sudden, and did not look at all like general paralysis. In the second case there was a gradual but very marked improvement. There had been no dramatic change, but the patient was a great deal better and seemed to have improved steadily since having malarial treatment. Dr. Bewley referred to the small degree of general illness which the malaria produced. On the evening of treatment the temperature might be high, but by next morning the patient was perfectly well, and there was none of the depression or weakness commonly seen with high fever.

Dr. H. R. C. RUTHERFORD referred to a report by Dr. S. J. Graham, of the Mental Hospital, Belfast. In 1923 Dr. Graham had treated 70 cases of G.P.I. with malaria, and was able to discharge 30, of whom 21 were absolutely well on discharge and remained well for periods varying from a year to 18 months. Nine went away against his advice, and of these two returned for further treatment; 28 did not improve, and one case failed to develop malaria. Dr. Graham had no doubt that this was a marvellous treatment, although it might not appear very scientific. Dr. John Dunne, of the Richmond Hospital, was also most enthusiastic about the treatment. Although Dr. Graham's cases had got well mentally, they did not improve much physically, and their Wassermann reaction was often still positive, even when they were cured. In this respect Dr. Bewley's results were more favourable.

Dr. E. S. HORGAN referred to the close correspondence between the Wassermann reaction and the colloidal gold test, especially when the Wassermann was done in double dilutions. It would be interesting, he said, to follow up the further clinical symptoms in these cases and see whether the improvement would continue parallel between the colloidal gold test and Wassermann reaction on the one hand, and the symptoms on the other.

Dr. NESBITT referred to a case under treatment.

Dr. A. R. PARSONS asked if there was any danger in giving malarial treatment, and said that it was very difficult to know what was going on in the first patient's brain, or what had caused the reaction.

Dr. G. BEWLEY, in replying, said that he had never had any difficulty in finding malarial parasites. In every film he had taken he had found parasites in every stage. The serological results were not nearly so important as the mental results. There was, of course, danger in the treatment. It was dangerous to allow rigors to run on for a long time and the onset of jaundice or hyperpyrexia was dangerous. He thought, however, that it was quite justifiable to subject a patient to very considerable risk if by doing so there was a good chance of curing an otherwise incurable disease.

---

## SECTION OF OBSTETRICS.

AT a meeting of this Section held on April 30th, Dr. D. G. MADILL, the President, took the chair, and Dr. J. S. QUIN reported a case of

### *Polycystic Kidneys Complicating Pregnancy.*

The patient was aged 35, married 12 years, 5-para, and came to see him in February, 1925, with a history of three months' amenorrhœa. She stated that she had had albuminuria in all the pregnancies except the first, and that in the last pregnancy, three years previously, she had been very seriously ill, the infant being born spontaneously at seven months.

The urine was found to be free from albumin. Diet was restricted and a regular daily evacuation of the bowels was ensured, but no more active treatment was considered necessary.

A fortnight later the patient complained of some hæmorrhage with discomfort and bearing-down, as well as great frequency and difficulty in micturition. There was still no albumin in the urine, but vaginal examination revealed an ulcerated and œdematous cervix protruding from the vagina, with a fundus enlarged to correspond with period of pregnancy (three and a half months), lying in retroversion. The cause of the prolapse was now evident. There were two large tumours easily palpable, one on each side of the lower abdomen. That on the right was globular and cystic, the size of a melon, and quite freely movable in all directions. On the left side a hard irregular mass with a limited range of mobility appeared to arise in the region of the pelvic brim, and extended upwards and laterally to the costal margin. No pain or discomfort was complained of, other than that due to the prolapse of the uterus. The uterus was replaced in position and a pessary inserted to retain the cervix at its normal level and allow of a reduction of the swelling and œdema of the tissues. A diagnosis of double ovarian tumours was made, but operation was postponed on account of the possibility of miscarriage and the septic condition of the cervix, and because it was considered that there would be less chance of interrupting the pregnancy at a later date if double ovariotomy had to be done.

The patient was kept under observation for four weeks. The hæmorrhage ceased and pregnancy appeared to be continuing normally; no albumin was at any time present in the urine. She began to complain, however, of pain in each flank, and the tumours, which up to this time had been palpable without discomfort, now became tender. Attacks of pain became more frequent and more severe, and as she was now four and a half months pregnant, operation was decided on. The abdomen was opened and the enlarged *fundus* was found lying in normal mid-line position, with two large retroperitoneal cystic masses, one on each side. The left tumour was a cyst the size of a melon resting on a bed of much smaller cysts, which gave it the feeling of having a pedicle; these sprang from the lower pole of the left kidney. The remainder of the renal tissue on this side was dotted with countless minute cysts, and the whole remainder of the organ was considerably enlarged. The base of the tumour, consisting of the lower pole of the kidney, was cut across. The cyst was removed, the raw area oversewn to control bleeding, and the suture line covered with a pad of the surrounding fat. The right kidney was completely disorganised, and consisted solely of grape-like cysts, no kidney tissue being evident to the naked eye. Some of the cysts were hæmorrhagic, and it was decided to remove the entire mass. This was done and a tube was brought out to the right loin through a small incision in the posterior wall. The peritoneum was closed on each side, and the pregnancy was then terminated by an incision through the fundus, the ovum being removed, and the uterine incision sutured as in a Cæsarean section. The tubes were finally ligated and cut, and the abdomen closed. The patient did quite well, and was passing normal quantities of urine within 24 hours; at no time during her convalescence did her condition give rise to any anxiety.

Since operation, said Dr. Quin, her condition had been quite good and she had been free from pain or discomfort. Her blood pressure at present was 205 and she was passing a very slightly increased amount of urine, of specific gravity 1014. The condition was, of course, progressive, and would eventually terminate in uræmia, but he thought that the treatment carried out might have staved off the crisis.

A specimen of fibroma of the anterior abdominal wall was shown by Dr. LOUIS CASSIDY, and Dr. GIBBON FITZGIBBON read the annual report of the Rotunda Hospital. A discussion followed.

## EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on May 5th, Prof. WILLIAM RUSSELL in the chair. Prof. HERMANN SAHLI and Sir ARCHIBALD GARROD were elected Corresponding Members of the Society.

Dr. CHARLES MCNEIL read a paper on

### *Scrofula and Tubercle*

with reference to ancient and modern doctrines of abnormal constitution in tuberculosis. The term tuberculosis, he said, was of recent origin and dated from the time of Laennec; it included glandular tuberculosis and pulmonary tuberculosis, which from the days of Greek medicine had been described as scrofula and phthisis. It was curious that the idea of constitution was associated with scrofula and phthisis from the earliest time, and its present survival was the direct tradition from the Hippocratic doctrine of a phlegmatic humour or disposition. In the Middle Ages scrofula appeared under a new guise as the king's evil, and for nearly 800 years its cure by the royal touch was practised by the kings of France and England. In the early period of Greek and Latin medicine scrofula and phthisis were not associated with one another, though in each the doctrine of a constitution was taught. But with the revival of a scientific study of medicine—notably by Cullen, who definitely proclaimed some kinship between scrofula and phthisis—an approximation between these two great clinical types of tuberculosis took place. Laennec's new doctrine of the tubercle as the cause of phthisis was a further and very important stage in progress (1820). But the doctrine of constitution, and especially of a scrofulous constitution, still dominated medical thought, this constitution being regarded as the direct cause of the manifestations of scrofula and phthisis; the idea of contagion in phthisis was deliberately rejected by Cullen, Laennec, and, even as late as 1875, by Watson. With the discovery of the tubercle bacillus by Koch (1882) the identity of scrofula and phthisis was established, Laennec's doctrine of the tubercle was vindicated, and the word tuberculosis became supreme. Scrofula had fallen at once from its high position and gradually disappeared from the everyday vocabulary of medicine. It was now, indeed, an obsolete and almost forgotten word, surviving merely in such phrases as "the scrofulous child," scrofulous conjunctivitis and keratitis, and scrofuloderma. The theory of constitution in tuberculosis had persisted after Koch's discovery in the changed form of a hereditary predisposition or tendency, but even so, it had steadily receded, and the recent investigations of Bernard (showing that the children of tuberculous parents, if protected from infection, did not contract the disease and were fully up to the average in health and vigour) had supplied further important evidence against it. The idea of a scrofulous constitution, however, still survived, especially in Germany, in connexion with certain types of tuberculosis in childhood, gland and bone tuberculosis, and those obstinate relapsing catarrhs of the eyes called scrofulous and strumous. It was taught (Heubner, Czerny, Escherich, Moro) that in such cases tuberculous infection was associated with the abnormal constitution, lymphatism, or status lymphaticus, and that in them the tuberculin reactions were unusually severe. Dr. McNeil showed slides illustrating the stigmata of the scrofulous child, the occurrence of severe tuberculin reactions in scrofulous conjunctivitis, and the morbid anatomy of status lymphaticus. Thyroid hyperplasia, he said, accompanied the lymphoid hyperplasia in status lymphaticus, and might be regarded as an essential part of its morbid anatomy; if this were established, the morbid anatomy of status lymphaticus in the child was identical with that of exophthalmic goitre in the adult. These facts, he thought, supplied some anatomical evidence of abnormal constitution in certain cases of tuberculosis in childhood. But this abnormal constitution was independent of tuberculous infection, since it was also found along with, and probably explained, certain rare fulminant types of many other infections in childhood, such as pneumonia, scarlet fever, measles, and chicken-pox. The abnormal constitution in the child which was termed status lymphaticus might be the counterpart of exophthalmic goitre in the adult, both being dependent upon some unknown disorder of general metabolism; but whether this was so or not there was no evidence for the very ancient doctrine of an abnormal constitution (or diathesis) peculiar to tuberculosis. If the old word scrofula were to be retained in medicine it should only signify glandular tuberculosis, which was a definite and important phase of tuberculous infection in childhood, and it should not imply any idea of constitution.

Dr. J. V. PATERSON spoke on the subject of scrofula and strumous keratitis. This condition of the eyes, he said, was commoner amongst our ancestors. At present it was only seen in hospital practice and never in private. It undoubtedly had a close relationship to tuberculosis. No other treatment was necessary than hygiene and good dieting. Treatment in the dark was now a thing of the past. It should be classed as a preventable disease.

Dr. ALEXANDER JAMES read a paper on

### *Scarlatina, Diphtheria, and Measles*

in their relations and inter-relations, from the medico-sociological standpoint. The effects of an infectious disease, he said, were governed first by its own virulence, and, secondly, by the constitutional strength of the individual, hereditary or acquired. He described the results of an investigation designed to ascertain whether strength and fitness to resist one infectious disease applied to other infectious diseases. For the purpose 918 cases were collected of scarlet fever, 610 of diphtheria, 238 of measles, and 111 of diphtheria carriers, all of them over 6 years of age. In addition the infectious diseases were studied in 1000 school-children. The results were tabulated as shown. (Previous illnesses are shown on the left; thus 75 per cent. of scarlet fever patients had previously had measles, 50 per cent. had had whooping-cough, and so on.)

Study of the table, said Dr. James, showed that the proportion of those who had had no previous infectious disease was high in measles and low in diphtheria. Taking into consideration the fact that measles was a very common disease, this seemed to show that those who could ward off measles could ward off other diseases better than their neighbours. To study constitutional fitness the cases were divided according to their severity into two groups, and the number of previous infectious diseases was found for each group. Of 918 cases of scarlet fever 877 were mild or moderate, and 41 severe or fatal. In the former group the percentage of previous infectious diseases was 1·73; in the latter it was 2·12. Further, in the latter group there was not one case that had not had previous infectious disease. Other diseases showed similar results. Certain individuals, moreover, showed a particular susceptibility. For instance, a boy of 7 years admitted to hospital with measles, contracted successively diphtheria, scarlet fever, and chicken-pox, whilst all the other patients in the wards he visited remained free.

| — | Scarlet fever. | Diphtheria. | Measles | Diph. carriers. | School-children |

Dr. D. WEBSTER, Dr. R. A. FLEMING, and Dr. ALEX. GOODALL took part in the discussion following Dr. JAMES's paper.

# Reviews and Notices of Books.

## THE ESSENTIALS OF MENTAL MEASUREMENT.

Third edition. By WILLIAM BROWN, M.D. Oxf., D.Sc., M.R.C.P. Lond., Wilde Reader in Mental Philosophy in the University of Oxford; Psychotherapist and Lecturer on Psychotherapy, King's College Hospital, London; and GODFREY H. THOMSON, D.Sc. Dunelm, Ph.D. Strasburg, Professor of Education, Armstrong College, Newcastle-upon-Tyne; Visiting Professor, Columbia University, New York, 1923–24. Cambridge University Press. 1925. Pp. 224. 17*s.* 6*d.*

THE chief alteration from the last edition of this book is the addition of a chapter summarising the present position of the controversy over the theories of general and special abilities. Fortunately, there are signs that the protagonists in this struggle are not quite so far apart as they appeared to be before, though some points of difference still remain. The existence of general ability—in the sense that a man who is good at one kind of mental work is usually above the average in others—is a fact which has always been accepted by both sides. The controversy arose over two different ways of explaining this fact. By Spearman's theory a general factor $g$ has a part in all our activities, hence the correlation between achievements in unlike performances. Each achievement is completely determined by the general factor and another factor specific to the activity in question. Thomson's sampling theory assumes that each activity is a sample of many factors, and correlations are caused by overlapping group factors common to several activities. Each side acknowledges the possibility of the rival theory in some cases.

The most acute point of difference was the validity of Spearman's criterion for "hierarchical order" (as a sign of the existence of $g$) among correlation coefficients. This criterion has now been replaced by another which appears to be more acceptable, but comprehensive tests by the new criterion have not as yet been published. A controversial point still held by Thomson is his argument that, philosophically and mathematically, the differences between really different correlation coefficients are of the same nature as fluctuations of sampling in truly equal correlation coefficients "for the variates are differing samples of the underlying elements." Hence *he believes* that a considerable degree of hierarchical order is natural among all sets of positive correlation coefficients—not among psychological measures alone. Here, again, the appeal to experience on a decisive scale has not yet been made. For those who are not familiar with the earlier editions of this book, we may say that it deals to some extent with methods of experimenting to obtain measurements of psychical processes, but to a larger extent with the methods of calculation applied to such data. The title would lead one to expect that the relative share of *attention* would have been reversed. In fact, the general impression given by the book is that the chief need of the science of psychology is to aim at improved methods of experimenting, and thus lessen the need for subsequent statistical treatment. The ordinary statistical methods are clearly but shortly described, and the book is to be recommended to psychologists as paying more attention than is often found in psychological text-books to the exact methods of the biometrical school and rather less to short-cut approximations. One short cut omitted might with advantage have been included—Pearson's $Q_2$ coefficient for a fourfold table. It has not the theoretical basis of his tetrachoric $r$, but in practice agrees well with it and is considerably quicker to calculate. The discussion of index correlation tacitly makes the common but, to say the least, debatable assumption that it is always the correlation of the ratios that is "spurious" for the object in view, and never the correlation of the elements. In the example of fitting a normal curve, on page 43, a hint might be given to beginners that *areas* are needed to compare with frequencies; not till page 78 are areas compared. The warning note on page 43 against curve fitting to only 29 observations might be repeated with even more force against using the "Goodness of Fit" test with cell numbers of the size found on page 79. These are only minor points in a book that, if somewhat too controversial in parts, is, nevertheless, of proved value.

## THE PHYSICIAN AND THE PUBLIC.

By LEONARD L. LANDIS, M.D., Chairman of the American Association of Independent Physicians, &c. Published by the Association. Pp. 349.

THE present-day code of medical ethics has, especially of late and in this country, been severely called in question, but it has on most occasions been arraigned only by members of the public when it has been described usually in quite fanciful terms. It is interesting to find that in America a medical man has decided "to break through the barriers of lifeless medical tradition and decaying dogma" and to advocate publicity as the greatest need of the profession; American doctors are encouraged to advertise directly to the public to secure practice, on the basis that "no advertising can be permanently successful which does not tell the truth." If such a doctrine exists beyond the Atlantic there must be many in America who ascribe to the *advertisement* columns of their papers an accuracy which is undeserved, while losing count of enormous fortunes made by exploitation. Dr. Landis considers that for the doctor direct advertisement is the only alternative to the methods of indirect advertising that the present code either allows or is powerless to prevent; such methods he reviews as ranging from "industriously getting a footing in the homes of wealthy or influential members of the community" to "an understanding with a janitor or local druggist" to recommend a practitioner.

It is hardly necessary to point out the fatal objections to direct advertising of any sort by professional men; they are all based on the fact that the appeal would be made to a public which could not criticise its veracity. Change of professional methods in the suggested direction would bring with it a new class of personality into the profession. Under the conditions of publicity which Dr. Landis enthusiastically visualises, the medical man, who based his professional work on the evolving principles of medicine, would no longer be able to keep his position in competition with an ever-increasing list of "best sellers." We do not think that among well-educated and progressive practitioners Dr. Landis's views will find much acceptation.

ROCKEFELLER INSTITUTE.

Studies from the Rockefeller Institute for Medical Research. Reprints, Vol. LV. 1926. Pp. 599.

THE results of investigations conducted at the Rockefeller Institute in New York or elsewhere under its auspices are first published in various journals. From time to time they are reprinted in volumes, of which this is the fifty-fifth, paged consecutively and indexed. Such collections form a record, in this case a very fine one, of an institution's activities, and they give a vague memory another chance of finding some paper by a forgotten author with a mislaid title. Otherwise they are not very useful, and in many ways workers in other places are better served by an annual summary of what has been done which enables fresh work to be placed in relation to what has gone before, which cannot be done by unannotated reprints of the complete originals; the Rothamsted Experimental Station and the Lister Institute issue such a digest each year in a convenient form. The papers in the present volume cover a wide range and their classification in the table of contents is not very helpful.

## JOURNALS.

BRITISH JOURNAL OF SURGERY.—The April number contains Sir D'Arcy Power's twentieth eponym on Thomas's hip splint, continued from last time.—R. M. Handfield-Jones gives a full description of the occurrence of chorionic carcinoma in the testicle, reports a fresh case, and brings the number of reported cases up to date.—E. D'Arcy McCrea reviews the anatomy and the physiology of the nerves of the stomach; he has investigated the results of nerve section on the tone and function of the organ, and he suggests that certain morbid conditions of the stomach may be treated with some success by this method in the future.—R. Campbell Begg reports a case of a solitary cyst of the kidney originating in a cavernous angeioma.—From the biochemical department of the Middlesex Hospital there comes an interesting report of the reliability of the various methods of estimating renal efficiency as the result of experiments carried out by I. Cohen, E. C. Dodds, and C. H. Shorney Webb. They consider that the blood-urea test is not a safe one, and recommend that the estimation of the uric acid content and the non-protein nitrogen content of the blood be relied on in the future.—R. L. Stewart discusses primary tumours of the ureters with a report of a case.—L. R. Fifield and R. J. McNeill Love analyse 78 cases of subphrenic abscess occurring at the London Hospital.—G. Bell and K. Inglis record a case of a hæmangeioma of the leg extending from the ankle to the knee, invading bone and soft tissues, and being so large as to necessitate amputation.—P. Manson-Bahr and A. L. Gregg describe the surgical treatment of chronic bacillary dysentery by cæcostomy and drainage.—A. Campbell describes a new method of closing clefts of the hard palate by mucous flaps leaving no raw areas in the mouth.—C. Dukes presents a study of the simple and benign tumours of the large intestine, and suggests that there is sufficient evidence that the carcinoma of the large bowel arises in an adenoma.—A. W. Adams reports a case of solitary cyst of the humerus and reviews the literature and the treatment.—G. Hadfield discusses fat necrosis of the breast and records a case. The following rare or obscure cases are recorded. F. Harvey: A pedunculated thyroid tumour at the base of the tongue, arising from the region of the foramen cæcum. W. W. Galbraith: An appendix with a pin penetrating it and fixing it to the liver. A. Piney: A fibromatous tumour containing osteoclast-like cells growing in the subcutaneous tissues. A. Fullerton: Sarcoma of the ileum in a boy of 3 years associated with an intussusception. W. Tyson: Hypernephroma of the gall-bladder. J. Morley: Fusiform dilatation of the duodenum simulating hour-glass stomach. H. Burrows: Implantation cyst of the terminal phalanx of the thumb. W. Sampson Handley: Reducible hernia of a lipoma of the knee-joint. Sir James Berry: Large salivary calculus which had undergone spontaneous fracture with eburnation of the broken surfaces.—The fourth number of the Pathological Atlas contains 15 tumours of the jaws, comprising the myelomata, cysts, and the odontomes.

# Reports and Analytical Records.

## PERGONIN (ANTIGONORRHOICUM).

(PREPARED BY DR. BOTT AND CO., FRANKFORT-ON-MAIN, GERMANY.)

THIS preparation is a coffee-coloured liquid put up into phials, each containing 21·5 c.cm. It claims to be an isocarbocyclic silver compound. On analysis the following results were obtained:—

| | |
|---|---|
| Colloidal silver .. .. .. | 0·15 per cent. |
| Protein .. .. .. .. | 0·41 " |
| Combined phenol .. .. .. | 3·00 " |
| Reaction .. .. .. .. | Neutral. |

Although the liquid had the odour of phenol this compound was not present in the free state, but on distillation the quantity mentioned above was found.

Pergonin appears to be colloidal silver in loose combination with protein and a substitution derivative of phenol. For use the contents of one phial are diluted with 6·5 oz. of 3 per cent. solution of sodium chloride, ½ oz. being used for each injection. Considerable claims are made for pergonin as being successful in the treatment of gonorrhœa.

## (1) EMULSION OF METAGEN AND COD-LIVER OIL; (2) BISMUTH SALICYLATE IN OIL.

(PARKE, DAVIS, AND CO., 50–54, BEAK-STREET, LONDON, W. 1.)

The first of these products is designed to supplement the well-known nutritive qualities of cod-liver oil with the other accessory food factors. Metagen is a physiologically tested preparation of vitamins of vegetable origin and emulsification is effected by employing fresh eggs which enhance still further the nutritive value. Its use is suggested for adults suffering from disorders of nutrition and for infants where it is desired to promote calcification of the bones, or delayed eruption of teeth, or to prevent the onset of rickets. Each fluid ounce of the product (28·5 c.cm.) contains 10 gr. (0·65 g.) of metagen and 200 minims (12 c.cm.) of the finest Norwegian cod-liver oil. The flavour is not unpalatable. The dose for adults is one tablespoonful, and for children one to three teaspoonfuls, three times a day after meals.

Bismuth salicylate in oil consists of the chemically pure salt in very fine powder, suspended in olive oil to which has been added 10 per cent. of camphor and creosote, with the view of preventing pain and irritation at the site of injection. As a spirochæticide the suspension may be given intramuscularly in all stages of syphilis, particularly those in which adequate doses of mercury or arsenic cannot be tolerated or where the spirochætes have acquired a tolerance for other drugs. The preparation is put up in boxes of six ampoules, each containing 2 gr. (0·13 g.) of bismuth salicylate in 17 minims (1 c.cm.) of oil. The size of the dose and the duration of treatment vary with the severity of the disease; 12–15 injections constitute the usual course. Patients should be directed to drink water freely while under bismuth treatment. Overdosage may produce symptoms similar to those of mercury overdosage.

ts, obstruction,

or damage are already illegal. When offences of this kind are committed by large and disorderly crowds in the temporary absence of sufficient police officers, it is the enforcement of the law, not the interpretation of it, which is the difficulty. Stone-throwing, assaults on drivers, overturning cars and setting fire to them are not more innocent because they occur during a strike; if anything, they are more criminal. The privilege of peaceful picketing does not extend to acts like these. The Trade Disputes Act of 1906 does not excuse them. "The immunity afforded by the 1906 Act," says a recent legal text-*book*, "*must be strictly limited to peaceful picketing.* Watching and besetting or trespass or any other improper act is still unlawful . . . So also, apparently, a prosecution for obstruction under the Highways Acts will still lie." No doubt this statement of the position is correct. It will be found in "Industrial Law," the volume published in 1924 by Sir HENRY SLESSER, K.C., and Mr. ARTHUR HENDERSON.

## IMMUNISATION AGAINST MEASLES.

SOME weeks ago[1] we drew attention to the damage done by measles amongst children in poor homes and in institutions, and suggested that immunisation with the serum of convalescents, if it is really as effective as is claimed, would be a procedure of real usefulness in everyday practice. In the *Medical Officer* of April 10th Dr. LUDWIG HEKTOEN and Dr. B. R. LOVETT, of Chicago, give an interesting account of the uses and limitations of this kind of serum therapy. The results they quote may not justify all the statements born of enthusiasm for the method, but they certainly support our contention that there is a good case for trying it in this country. VON TORDAY, it is remarked, summarised the cases up to 1923, and found that out of 2000 there were less than 3 per cent. of failures—that is to say, of children on whom convalescent serum did not confer protection. At the Durand Hospital, Chicago, of 57 susceptible children exposed to infection the nine who were not treated all developed measles, but of the 48 who were given serum only four became sick, and three of these had received it too late to get adequate protection. Convalescent serum is prepared at the Durand Hospital by taking 6 to 10 oz. of blood from the vein of an adult or older child after the temperature has been normal for four days following measles. After Wassermann tests and cultures to ensure sterility, the serums from several persons are mixed, 0·25 per cent. *of tricresol is added for preservation*, and the serum is sealed in 5 c.cm. vials. These are kept on ice and the immune substances remain potent for six months or more. Naturally, it is not always easy to get a large supply of this serum, and whole blood from a member of the family who has had measles may be used instead. Whole blood has to be given in greater quantity, and if an adult has not had measles since infancy a rather large amount of his blood is needed to confer passive immunity on a susceptible child. VON TORDAY gave 20 c.cm. of blood drawn from older children or adults to 116 children on days from the second to the sixth after exposure. Twelve developed modified measles, the rest were protected, and none had a typical attack. The results of immunising with whole blood are said to be less certain than when serum is used, but, in the opinion of HEKTOEN and LOVETT, the method is valuable because it is so easily carried out in private practice when no prepared serum is available. As we have already pointed out, the passive immunity produced by early injection of serum, although convenient in certain circumstances, only lasts a few months. Its use corresponds exactly to the administration of diphtheria antitoxin for prophylactic purposes in institutions during epidemics. If, however, the attack is not prevented entirely and is only modified, the result is said to be permanent immunity at the expense of a mild illness. HEKTOEN and LOVETT say that it is not easy to arrange matters so that this slight attack is sure to occur, but it is clearly a satisfactory thing to bring off.

---

[1] THE LANCET, March 27th, p. 668.

To show the proper dosage for modified or full protection they quote a table from ZINGHER as follows:—

| | Days after exposure. | | |
|---|---|---|---|
| *For complete protection:* .. | 1–4 | 5–6 | 7–8 |
| Convalescent serum .. | 2·5–3 c.cm. | 5 c.cm. | 7·5 c.cm. |
| Recently recovered serum .. | 5–6 | 7·5 | 10 |
| Immune adult's serum .. | 10 | 15 | 20 |
| *For modified attacks:* | 1–5 | | 5–10 |
| Convalescent serum .. | 1·5 c.cm. | | 2·5 c.cm. |
| Recently recovered serum .. | 2·5 | | 5 |
| Immune adult's serum .. | 5 | | 10 |

These amounts are for serum; if whole blood is used the amount should be twice as great.

In concluding their paper they say:—

> The most rational procedure for children over 5 years old, who are in good condition and living in their own homes, is to produce a modified attack if possible. In children's hospitals and institutions, where it is important to stop the outbreak of measles as soon as possible, injections of serum should be early and adequate to prevent entirely. Children under 5 years old and those who have recently suffered from other diseases, especially tuberculous children, should also be protected from the attack of measles.

It is not, of course, convenient that human blood should be used for the supply of immune serum, and any great success in eliminating the disease might lead to a shortage of convalescents from whom it could be got. The question arises, therefore, whether it would not be possible to secure a supply from animals. To do this it is necessary to provoke an active immunity in the animals concerned, which is only done conveniently when the virus can be handled and modified. Dr. RUTH TUNNICLIFF, of Chicago, has isolated, from cases of measles, a Gram-positive green-producing diplococcus which, on being injected into goats, raises their immunity so much that their serum (it is said) protects human beings as efficiently as does the serum of convalescents. She considers, however, that the experiment has not been done often enough to justify any definite conclusions as yet. More recently a report has been published in the *Journal of the American Medical Association* (March 27th, 1926), by Dr. N. S. FERRY and Mr. L. W. FISHER, who report the isolation of a streptococcus of the *viridans* type from the blood of measles patients. To this organism they have given the singular name of *Streptococcus morbilli*, and they claim that it produces a toxin which gives for measles all the reactions which the Dick toxin gives for scarlet fever and which are generally considered weighty evidence in favour of streptococci being of ætiological importance in the latter disease. As there are now at least two streptococcal claimants for the causal rôle in measles, judgment must be deferred until more extended observations have been made and further reports received. Other interesting work has, of course, been done along quite different lines. In 1915 HERMAN,[1] taking advantage of the fact that infants do not contract measles until they are a few months old, inoculated their throats with material from the nose of infectious patients and reported that they were fully and harmlessly protected. HEKTOEN and LOVETT, however, regard such methods as largely discredited. The production of active immunity, as they remark, is still in the experimental stage, but this is evidently a stage of promise.

## MEDICAL BENEVOLENCE.

THE last report of the committee of management of the Royal Medical Benevolent Fund shows, as well as an increase in new subscriptions, some substantial legacies—Sir RICKMAN GODLEE, for example, has bequeathed a contingent legacy of £5000, while the will of Dr. M. G. EVANS has benefited the institution to the extent of over £3000. There were many special donations, among which may be noted the sums of £1000 from Dr. WILLIAM TINKER, of 500 guineas from the Medical Insurance Agency, and of £50 from a subscriber whose admirable attitude may be quoted, as it appears in the report; his donation was based on two guineas for every year he had practised, a covering letter containing the following words: "I have a very guilty conscience for not having supported the most excellent Fund." We have a feeling that other consciences may be aroused by this piece of intelligent generosity. The income of the Fund, derived from subscriptions and donations and from invested property, has gone up during the year and the amount expended in grants has risen proportionately. Altogether 559 persons have been relieved by grants and annuities. The report was noted in detail in our issue of May 1st (p. 927), and those who read it will observe that this tale of prosperity is a sorely qualified one. Progress is reported, but it is a progress that does not even keep pace with the demands upon medical benevolence, still less does it enable the formation of any great scheme for assistance by way of education to the young dependents professionally connected with all of us. And that is the ideal to which attention should be directed.

The rising sense of responsibility which the medical profession as a whole is feeling towards those of their colleagues on whom fate, for one reason or another, has pressed hardly, was sensed last year in an instruction given by the Representative Body of the British Medical Association to the Council of the Association to the effect that a Charities Committee should be constituted by the Association with the duty to direct the attention of the members to the financial and educational hardships which arise as a result of misfortune through ill-health or through premature death. The object of the Committee will be to appeal for contributions to meet those hardships, and the Council in office will act as trustees for any fund that results, while grants from the fund will be allotted either to such medical benevolent organisations as the Charities Committee may deem advisable or in any directions that individual donors may select. The scheme is bound to be of great benefit to the existing charities, and will be, further, a form of that coöperation of activities which it has so often been pointed out in these columns is the only way to secure both massed opportunities for relieving distress and due powers of discretion in the bestowal of assistance. Such coöperation has already resulted in substantial good in educational directions, for the Medical Insurance Agency, started as a joint movement by the *British Medical Journal* and THE LANCET, and noted above as a fine friend to the Benevolent Fund, has now become one of the most substantial and regular benefactors of Epsom College, which (as may be seen from the brief report on a later page) is the great example of medical benevolence applied to the upbringing of the children of doctors.

---

[1] In a recent article this work was inadvertently ascribed to Morey, whose name does not appear elsewhere in the literature of the subject.

The Benevolent Fund and Epsom College, having the common purpose of alleviating misfortune in the medical profession, are directed the one towards the later and the other towards the earlier conditions of particular need. Pensions and grants from the Fund make easier the lives of those who can no longer work, or of their dependents for whom they have been unable to make adequate provision. No appeal to the more fortunate in the medical constituency can be more moving, and it is the great desire of those who have for long supported the Fund that the regular disbursements should be upon a more liberal scale. The sad stories narrated month by month in the medical journals indicate the fundamental necessities which have to be met, and no doubt the small allotments which the Fund can make count for a large increase in the security and happiness of the recipients. But with the purchasing power of money what it is to-day, the stewards of the Fund feel that the payments ought to be on a higher scale, and we trust that they may receive many more annual subscriptions towards the accomplishment of their purpose. The supporters of the Epsom Foundation, though they too dispense certain pensions, have before them mainly the great ideal that the children of the less fortunate medical men should not be deprived of the equipment for life which it had been designed that they should receive. No greater relief can be given to anxious parents, whether living and over-burdened with care or widows with slender resources, than to feel that their children will obtain those early opportunities for making a career which it is the prime object of self-respecting families to provide for their offspring. We recommend, therefore, with equal urgency the Fund and the College to the notice of all the medical profession, though it will be fitting here to add a word of warning to intending testators. These two admirable institutions contain in their full official titles adjectives common to both, and before now it has required the costly intervention of the law to decide by interpretation of the phraseology which of them a will was intended to benefit. The two institutions are properly supplementary to each other, and benefactors should be careful not to force them into apparent opposition by confused expressions of their intentions.

* * *

# A DEFINITION OF BLINDNESS.

A REPORT on blindness in Glasgow has recently been published with an introduction by Dr. A. S. M. Macgregor, the medical officer of health. The statistical inquiry into the causes of loss of vision among the adult blind was undertaken by Dr. A. Freeland Fergus and Dr. J. L. Halliday, but unfortunately its utility is to a great extent marred by the entire absence of any mention of the standard of blindness concerned. Thus measles was found to be responsible for 35 cases of blindness—that is, 2·9 per cent. of the total number. "Measles," to quote the report, "as a cause of blindness acts mainly by producing ulceration of the cornea. In the severer cases it may cause complete destruction of the eye." Now corneal ulceration, and especially the phlyctenular ulceration that is a common sequela of measles, is a not uncommon cause of defective vision, but the standard of blindness would have to be a fairly liberal one before many were included who owed their disability to this cause alone. At any rate, this would be the case in London, and cases of panophthalmitis following measles, though they do occur, are so rare that we should be surprised to find that the percentage rate was materially affected from this cause. Similarly one is in the dark as to what degree of blindness affected the 38 cases of extreme myopia and the five of extreme hypermetropia. If by "blindness" is meant "too blind to carry on their usual occupation" this should have been stated, but in default of some agreement as to the amount of vision necessary in various occupations such statistics would be of little value. To take a definite standard of visual acuity is a more hopeful method, and in an examination of adults there is no excuse for omitting this, but in estimating blindness it is not in itself sufficient, for cases of diminished fields of vision such as occur in glaucoma or retinitis pigmentosa may cause a disabling degree of blindness even while retaining comparatively good central vision.

This matter is one of considerable practical importance. Under the Blind Persons Act a considerable amount of public money is now being expended in subsidising the training of the blind, in supplementing their earnings, and in granting them old age pensions ten years earlier than the rest of the population. By the Act of 1920 blindness was defined to include persons "so blind as to be unable to perform any work for which eyesight is essential." For the purpose of interpreting this definition the Ministry of Health are now demanding somewhat detailed particulars of the blindness of applicants for the nation's bounty, and there seems to be good reason why they should do so. Their "Circular 681," recently issued, quotes from the report of the Section of Ophthalmology of the Royal Society of Medicine, issued in 1915, as follows:—

> "Experience shows that persons whose acuity of vision (refractive error being corrected) is below one-twentieth of the normal (3/60 Snellen) are usually unable to perform work requiring eyesight, while persons with vision better than one-tenth (6/60 Snellen) are usually able to perform some such work. Persons with intermediate degrees may or may not be able; much depends on intelligence and bodily strength, and much on the nature of the blindness.
>
> "A person whose so-called blindness depends on defects in the centre of the visual field may fail to reach a given standard, and yet be able to perform some kinds of work requiring eyesight, while another person suffering from great contraction of the field of vision may surpass the same standard and yet be unable to walk alone, or to do any kind of work requiring eyesight."

Having regard to this considered statement the circular intimates that any person whose visual acuity with correcting glasses is greater than 6/60 cannot be considered blind within the meaning of the Act unless the defect of eyesight includes such special conditions as a great contraction of the field of vision. The definition so arrived at is more stringent than that given in the Education Act of 1921, for the purposes of which Act a blind child is one who is "too blind to be able to read the ordinary school books used by children"; but, as the circular remarks, there is nothing to preclude the provision under the regulations of the Board of Education of facilities for the training of the partially blind. Indeed, an extension of such facilities is urgently required, especially in the interest of a large number of high myopes. For the selection and training of those who are likely to be qualified for Government assistance under the Blind Persons Act the approximate definition of what we may term industrial blindness will be of great help. There is still no hard-and-fast line, but in laying it down that anyone possessing a visual acuity of 6/60 is not considered blind unless suffering from further disabilities such as contracted field, the Ministry cannot be considered unfair. The circular should be at once an assistance to those who are responsible for the selection of cases suitable for admission to institutes for the education and training of the blind, and a spur to those education authorities who have not yet realised the necessity of providing special training of a different sort for the partially blind.

# Annotations.

"Ne quid nimis."

## ECONOMIC BIOLOGY.

THE heavy financial cost of some antimalarial engineering undertakings and their failure to reduce malaria have warned medical men to be cautious in advice—sometimes warned them off advice altogether—on this matter. A recent book[1] does excellently in equipping medical advisers to meet their difficulties with greater confidence. Mr. Home notes that the failure of the French company to excavate the Panama Canal is one example only of the political and economic results due to malaria. Gorgas stated that the company lost 22,000 men in their attempt. The engineer is principally concerned with the economic side of the matter (and, we would add, the medical man ignores this side at the peril of his reputation). When labour is temporarily resident in a district—e.g., for railway construction or irrigation works, if the cost of provisional measures, such as oiling, temporary drainage, screening of quarters, plus their upkeep during execution of works, equal the estimated loss due to sickness, it pays financially. Where labour is resident the estimated loss due to sickness must be equal to the interest and sinking fund charges on the cost of permanent antimalarial works, plus cost of efficient upkeep, to pay financially. If the cost of the latter be greater than the former the malarial conditions are too serious to be tackled economically. Antimalarial works are really contingent expenses to works carried out by administration and part of the works' cost in a contract. In the Panama Canal antimalarial works have cost 5½ per cent. of the construction cost, and it is improbable that the large body of white and black labour could have been kept together without such expenditure. In the tropics railway and road construction is often responsible for increasing malaria. Culverts are sometimes placed too high completely to drain off water from the upside stream. In level country the bank, owing to insufficient number or water area in culverts or bridges, sometimes acts as a dam, holding up the cross drainage, and so on. The engineer responsible should give special attention to the drainage within two miles of inhabited places, ample water area being allowed for quick discharge in sections which threaten to hold up water. In populated districts antimalarial work should be regarded as a health measure benefiting the whole district, and be mainly financed and maintained as such, disregarding possible benefits to individual properties or undertakings.

In the indispensable preparatory work of antimalarial schemes it is for the entomologist to find out and chart the occurrence of different species of mosquitoes in the district, bearing in mind that while anophelines include all the species capable of transmitting malaria, some of the species in this group are not dangerous in this respect. The medical officer must discover definitely which species are the local vectors of the malarial parasite; for malarial surveys have disclosed important and unexpected facts. Thus, in Bombay, malaria did not arise from swamps around the city; the vector was *A. stephensi*, breeding in the wells of private houses. In the Andamans *A. ludlowi*, from the brackish creeks, is the vector, and the mosquitoes from the rice-fields are innocuous. In Mauritius it was found that all works' plans, 1908–22, had been based on the assumption that the only important malaria vector was *A. costalis*; further research revealed *A. funestus* to be an equally, if not more, important vector, and under certain conditions anti-*costalis* measures favour the breeding of *funestus*. One of the most dangerous malaria carriers of the Malay Peninsula is actually attracted to waters opened up by removal of forest. Anopheline breeding-places may be dealt with by (1) destroying all actual or potential breeding-places of all anopheles; this requires little preliminary investigation, but is often costly. (2) Destroying only the actual or potential breeding-places of those species proved to be dangerous in the district; this requires extensive preliminary investigation, but is less costly. It is not easy, however, to ascertain which are the local vectors and what are their breeding habits. The methods of identification of anopheles of lowland and hill drainage, of antimalarial services, and the biological means of attack are all dealt with clearly and informingly illustrated in the book before us, which, although primarily intended for the engineer, should be read with equal care by the medical officer in the tropics; its place is beside Alcock's Entomology. Mr. Home's experience on the Central American coast, the West Indies, West Coast of Africa, Egypt, and Syria would by itself command attention; but there is more to it than that; he is in love with his subject so much as to have led him to acquire, and expound, accurate knowledge of biological matters outside of engineering, yet bearing directly and importantly on the antimalarial engineering. He has thus gone, possibly unwittingly, half way to meet his colleague, the medical sanitarian, with whom he can talk in the gate of economic biology. Now it is the turn of the medical sanitarian to talk economic engineering with the engineer. So far as malarial problems be concerned this book will enable the doctor to do so, for it provides the necessary information concisely and attractively set forth. Lieut.-Colonel W. P. MacArthur contributes an enlightening chapter on mosquito netting; this most important means of individual prophylaxis is too often neglected for the doubtful practice of daily quinine taking, and to judge from their writings the authorities on malaria prevention know little of the mosquito net. In hot climates netting should not be finer than is necessary; the author's experiments and observations show that a net mesh 25 to 26 holes per square inch woven of 40/60 or 30's cotton will exclude mosquitoes. This is a welcome pronouncement, for nearly all have thought a far finer mesh to be necessary. Dr. P. A. Buxton gives a chapter on applied entomology, and there is one dealing with the pH values of water as they affect the contained fauna and flora. Mr. Home deserves congratulation on having produced a volume which has long been needed, for though most of the facts here recorded have already been published by many workers in different journals and official reports, they are here brought all together, well illustrated, and their inter-relations and varying significance clearly indicated.

## HIGH PROTEIN DIETS AND RENAL INSUFFICIENCY.

THE combination of hyperpiesis with renal insufficiency is so common in clinical practice, and the treatment of the condition remains so unsatisfactory that all experimental work on the subject is of interest. Retention of nitrogenous products in the blood, as shown by an excess of urea, non-protein nitrogen, and creatinin is a commonly occurring feature in such disease, and the logical therapeutic deduction from such findings is to place their subjects on a diet containing as small a proportion of protein as is possible. Unfortunately, clinical experience is far from giving its blessing to this procedure; results are disappointing. The diabetic, with hyperglycæmia, responds immediately to an adjustment of his diet, the nephritic does not. No solution to the problem is yet forthcoming, but some suggestive experimental work is in progress. Amongst such work may be quoted that of H. Anderson at the University of Minnesota Medical School. This observer has repeated and elaborated[1] the classical experiments of Rose Bradford, by removing a portion of one kidney in animals and, at a subsequent operation, removing the whole of the second kidney. Confirming Bradford's work, he finds that death is always produced rapidly in rabbits if more than 70 per cent. of the total kidney substance is removed. If, however, amounts varying from 62–68 per cent. are removed, the animals survive for a considerable time, a large proportion dying of renal failure in a few months, the remainder surviving indefinitely, the deciding factor between death and survival being whether the remaining portion of kidney hypertrophies and escapes infection, or whether infarction, pyelitis, or calculus occurs (probably as an accidental result of operative interference), and produces progressive disease in the fragment. On these animals with renal insufficiency Anderson has made many interesting observations. Analysis of the blood showed constant and considerable increase in the nitrogenous constituents, notably in the urea and creatinin, whilst urinary analysis showed albuminuria in most cases with a constant diminution in the power of the kidney to eliminate a concentrated urine. Observations on the blood pressure, on the other hand, yielded surprising results. In no case was there any appreciable increase in the arterial tension, nor were changes in the fundus oculi discovered. These results were given both by those animals kept on a normal diet and by a special group fed with a diet particularly rich in protein. It was found that in all animals observed, whether with normal or with defective kidneys, high protein diet caused renal hypertrophy, but there was no evidence that the diet had any harmful effect on the partially nephrectomised animals beyond accentuating the nitrogen retention in the blood. Arterio-sclerosis was certainly seen in the aorta of the animals taking the increased protein, but this change did not extend to any of the smaller arteries, nor was it the result of the impaired renal function, for it occurred equally markedly in those rabbits whose kidneys were normal.

## OSSIFICATION OF THE HYOID APPARATUS.

THE development of radiography has transferred several abnormal bony conditions from the note-book of the anatomist to the hands of the surgeon. First described as an anatomical peculiarity by Geoffroy-St. Hilaire in 1818, ossification of the stylohyoid ligaments has been studied as a clinical problem by von Eicken and Olivier. Dr. Adrien Harburger has recently said all there is at present to say about this interesting subject, basing his observations on 40 cases.[1] The symptom-complex produced by this abnormal slip of bone in the throat is a vicious circle of painful dysphagia and reflex increased salivation calling for repeated deglutition. The typical case is a woman of about 30 who has consulted many physicians, without avail, for an increasing difficulty in swallowing. She has noticed the steady development of a sharp pain in the throat, usually on the left side, aggravated by the passage of any food, especially solids. She has a scraping sensation in the pharynx, which feels as if a sharp point were piercing it at a spot which she can localise accurately. Sometimes the pain passes up to the ear and causes a little deafness. She may come into the consulting room dribbling the excessive saliva which dread of pain forbids her to swallow. When she speaks a certain mechanical dysphonia may be observed on the high notes. She will probably be able to point out a reddened and tender rod of bone across the tonsil or one of its pillars, or a ridge in the back of the mouth or nasopharynx. The progress of the case is slow but steadily progressive, until the pain necessitates resection of the styloid process, which is invariably successful. As in the parallel condition of cervical rib, the ossification may be present without causing symptoms.

Out of 115 cases collected by Dr. Harburger, only 20 gave trouble, and the malformation was discovered by chance on removing a tonsil or on making a thorough examination for some other reason. He lays stress on the *necessity for palpating* the ossicle before making the diagnosis; to see the ridge is not enough. The anterior pillar, the tonsillar fossa, the posterior pillar, and the lateral wall of the pharynx should be palpated methodically from above downwards, and the size, direction, and transverse mobility of the bone carefully estimated. There is no problem of differential diagnosis when an X ray has been taken; this should be done in profile with the head extended and the beam centred on the angle of the jaw. Unless this is done there may be confusion with cases of cartilaginous nodules or calculi in the tonsil—found in 84 per cent. of normal cases, according to Dr. Harburger—or even with an isolated ceratohyal nodule or a calculus in Wharton's duct. Such nodules have no connexion with the cranium or the hyoid, and the resistance they offer is within the tonsil and not outside it. The operation for resection should be preceded by a tonsillectomy, as this is a palliative which occasionally cures the symptoms. It is inevitable if the resection is to be performed through the tonsillar fossa, a route which is often convenient. If the abnormal ossification is only discovered in the course of a tonsillectomy, it is simply exposed and cut off with strong scissors or a bone-cutter. Very often the tonsil adheres so tightly to the bone that it cannot be removed without it. If the operation is for removal of the bone alone the patient should be prepared as for a tonsillectomy and the anæsthetic for choice should be local. The ridge made by the bone is incised upon and the resection made as extensive as possible. With ordinary care there is no danger of touching either carotid at this level, but the resection must not be carried up the styloid process where the external carotid and cranial nerves lie close to the bone. With careful hæmostasis the operation should give no troublesome after-results. This condition is one of those uncommon abnormalities which are only recognised if they are always borne in mind, and laryngologists will be grateful to Dr. Harburger for his review.

## INSULIN IN VOMITING AND ECLAMPSIA.

A COMMENT on the treatment of excessive vomiting and eclampsia by means of insulin lately appeared in the *Journal of the American Medical Association* (Feb. 20th). After a brief review of the statistics of vomiting in pregnancy, the article refers to the work of Thalhimer who, it may be remembered, recommended the use of insulin and glucose in all conditions inducing acidosis, whether associated with diabetes mellitus or not. He has reported very *good results* by the application of this method of treatment to the toxæmia of pregnancy. The summary of his method is as follows: 1000 c.cm. of warm 10 per cent. glucose solution are injected intravenously at the rate of 200–300 per hour. A quarter of an hour after the injection has been commenced 10 units of insulin are given hypodermically. Similar doses of insulin are given throughout the injection until 30 units in all have been administered. Thalhimer has also used this method in eclampsia, and he states that it is particularly successful if there is ketosis. He does not recommend that this form of treatment should be used alone in cases of eclampsia, but suggests that some form of anti-eclamptic measures such as a Stroganoff treatment should be adopted as well.

In a later issue (March 27th) of the same journal Paul Titus, of Pittsburgh, strongly criticises this kind of treatment. He says that insulin should *not* be added to the glucose injections given for the vomiting of pregnancy and that "it seems positively dangerous in eclampsia," and quotes the opinion of the Toronto group as contained in the following statement from *Medicine* (August, 1924), by W. R. Campbell and J. J. R. Macleod:—

> "The use of insulin in pernicious vomiting in pregnancy is, in our opinion, unnecessary. No case of post-operative acidosis has required it, and it is difficult to see what purpose it could serve. Its use in non-ketonic acidoses is even more questionable, and, indeed, one may be permitted to doubt its value in conditions other than those in which there is a distinct deficiency of endogenous insulin production. There

---

[1] La Vie Médicale, March 18th, 1926.

who insist on regarding all the ills the flesh is heir to as due to an indefinite endocrine unbalance will do well to pause before applying insulin recklessly. Insulin is a powerful drug. . . . Thalhimer suggested the use of insulin in addition to glucose to control the condition [vomiting of pregnancy] in severe cases. It is difficult to appreciate the use of the drug in this type of case. In Toronto no case of uncomplicated pernicious vomiting sufficiently severe to warrant the trial of insulin in addition to fluids and glucose has been encountered in the last two years."

From this it is evident that the use of insulin in toxæmia of pregnancy or eclampsia should certainly not be regarded as of proved value, and the same is true of its use in the malnutrition of infants in spite of satisfactory results summarised in the *Boston Medical and Surgical Journal* (April 8th).

## BACTERIAL INFECTION AND ACCIDENTAL HÆMORRHAGE.

AT a recent meeting of the Edinburgh Obstetrical Society Dr. F. J. Browne gave an account of some interesting experimental work carried out by him upon the ætiology of accidental hæmorrhage and placental infarction, which has already been reported briefly in our columns.[1] To recapitulate the gist of the statement there set out, Dr. Browne found that in many of the cases of accidental uterine hæmorrhage in the puerperium coming under his observation a history suggestive of chronic nephritis could be obtained. In endeavouring to reproduce the clinical conditions experimentally he induced a chronic nephritis in rabbits by continued poisoning with sodium oxalate, by the methods carried out and investigated by Shaw Dunn, Dible, Haworth, Jones, and McSwiney at Manchester. This procedure will set up a chronic tubular nephritis, whose incidence and course can be followed by renal functional tests, which ultimately proceeds to renal fibrosis. Dr. Browne found that if such animals were allowed to become pregnant, and during the pregnancy a further small dose of oxalate was administered—which has the effect of causing an exacerbation of the nephritis—and this was followed upon the next day by the intravenous injection of a small quantity of a saline suspension of *B. pyocyaneus*, the result in the eight cases in which the experiment was tried was the occurrence of uterine hæmorrhage with the production of placental infarcts. Further experiments showed that the bacterial factor alone was sometimes sufficient to produce this result in the presence of damaged kidneys, and that it was associated in such cases with an exacerbation of the nephritis as evidenced by a rise in the urea content of the blood. The general result which emerged from other experiments was that whenever uterine hæmorrhage in the gravid animal was successfully produced by any of the methods tried it was associated with an exacerbation of the nephritic condition, if previous chronic nephritis was present. It was also found that in non-nephritic animals the production of an acute nephritis sometimes sufficed to produce hæmorrhage.

The main outcome of these experiments, which are of great interest in connexion with the clinical problem, is to show the close relationship which may exist between the accidental hæmorrhage of the pregnant animal and toxic states. It is evident that the latter condition is the important factor and the mere means by which the kidney was damaged are of less significance, although for the purposes of experiment no doubt a certain technique will produce the grade of injury most likely to be associated with the hæmorrhage. An animal with existing renal insufficiency has no reserve excretory power, and any factor, intrinsic or extrinsic, causing further damage to the kidneys will increase the effects of the renal insufficiency—the toxæmia, to use a much abused word—whose existence is most conveniently demonstrated by the associated increased head of urea in the blood. Such additional damage might be caused in a variety of ways. Dr. Browne has employed, *inter alia*, injections of *B. pyocyaneus* and notes that the coliform group of organisms are especially potent in producing a positive result. The toxicity of this group for the rabbit and their especial tendency to produce renal lesions has long been recognised, and typical glomerulo-nephritis has been caused by their injection, both alone and in association with known toxic substances. We may assume, therefore, that the organisms in question in these experiments have acted chiefly as damaging agents upon an inefficient kidney and not in any specific way upon the uterus, and we do not, nor do we suppose does Dr. Browne, draw any inferences as to spontaneous infection, as such, being a factor in the production of this type of hæmorrhage in the human subject.

The suggestive work which we have outlined above raises the question once again, and in a more specific form, of the exact statistical relationship of albuminuria and renal insufficiency to accidental hæmorrhage, and the possibility of including at all events certain forms of this condition amongst the toxæmias of pregnancy. We are not aware of any extensive investigation of this matter, but no doubt the records of our maternity hospitals contain abundant information as to the former point and modern methods can quickly reply to the latter. In the meantime these extremely important experiments point out the necessity, nowadays fortunately well recognised, of the increasing surveillance of the pregnant woman and the careful examination of renal function in all cases in which a previous pregnancy has been associated with accidental hæmorrhage or where renal damage is known to coexist.

## ENDEMIC GOITRE IN NEW ZEALAND.

New Zealand is admittedly one of the healthiest countries in the world. It lies entirely within the temperate zone, and its climate is very nearly that deduced by Taylor and Huntington as the optimum for the human race. It has neither venomous animals nor disease-producing parasites; malaria and typhus are unknown, and its inhabitants maintain a high standard of sanitation and personal hygiene. It is curious that in a country so favoured endemic goitre should constitute a serious problem, and no less curious that so little should have been written and done about it. It was only after an absence of five years from his native soil of Canterbury that Dr. C. E. Hercus, of the University of Otago, realised the high incidence of goitre there, and determined to study its extent. He was assisted in this task by Dr. W. Noel Benson, professor of geology, and Mr. C. L. Carter, lecturer in chemistry. They extended their researches over the whole country, and have embodied their results in a thorough and attractively written monograph,[1] which will, it is to be hoped, stimulate and direct the efforts of the Government to solve an urgent problem. Besides being a distressing deformity, goitre is the brother of myxœdema and the father of cretinism. Previous figures of incidence, taken from recruiting and notification records, were deemed of little value, and Dr. Hercus started out in 1920 to determine the incidence of thyroid enlargement among the school-children of Canterbury and Westland. He combined the methods of inspection and palpation and found that readings taken by different observers varied by less than 5 per cent. The results were divided into five arbitrary categories similar to those of Marine and Kimball,[2] and the summarised results of the examination of 14,916 children were: normal, 39 per cent.; incipient enlargement, 29 per cent.; slight enlargement, 26 per cent.; medium enlargement, 5 per cent.; and massive enlargement, 1 per cent. The age-curve in girls rises sharply from 5 years to puberty (about 12) and bends, though still ascending, towards a maximum at 16, whence it falls. The boys' curve is much flatter and its highest, at puberty, is level with the girls' curve at 6–7. Fellenberg's[*] discovery of iodine in the menstrual blood suggests the reason why the deficiency persists in girls after puberty. 90 per cent. of the incipient enlargements occurred at the junction of the isthmus and the right lobe. In three cases only was the left lobe enlarged and the remainder of the gland normal. Thus the incidence of recognisable goitre among white New Zealand school-children reaches the remarkable figure of 32 per cent., though among Maori children for some unknown reason it is only 25–30 per cent. Dr. Hercus and his colleagues found that this incidence is roughly proportional to the average amount of iodine in the soil, and therefore to the amount present in the plant and animal food or the drinking-water of the population. Goitre does not necessarily go with mountains and limestone, nor is the comparative immunity of coastal districts due to air-borne iodine. The essential factor is the iodine in the soil. The New Zealand school medical service have, since 1923, been issuing free potassium iodide in 1 gr. pills (to be taken weekly) to all school-children in endemic areas. No child has yet shown any unfavourable symptoms from this very large dose—about 300 times the amount the gland requires. Nevertheless, there are serious objections to any scheme of prophylaxis that is confined to school-children. Endemic goitre is largely hereditary, and if the number of children of pre-school age whose thyroids are already enlarged is to be reduced, it is obvious that the important recipient of iodine is the pregnant mother. The authors hold that to restrict the supply of iodine solely to the school period is merely to trifle with the problem, and that the aim of the State should be to provide sufficient iodine for every inhabitant of a goitrous area for the whole of his life. They recommend the general use of table-salt containing 1/200,000 of potassium iodide, which is practically the *Vollsalz* used as a prophylactic in parts of Switzerland at a cost of not more than one-tenth of a penny a year for each inhabitant.

## NATIONAL PHYSICAL LABORATORY.

THE report of the National Physical Laboratory summarises the activities of the institution during the past year. During this time a considerable amount of successful research has been done, whilst the fundamental work of the laboratory in maintaining standards of measurement has received due attention. The ever-increasing demand for the investigation of physical problems necessitates better accommodation for the Physics Department, and it is hoped that it may be possible in the near future to erect a building suitable for Physical Research. Of immediate interest to the medical profession are those sections of the report relating to radiology and sound. The Radiology Department has continued its working association with the X Ray and Radium Protection Committee which has entailed the inspection of over 70 different hospitals and a considerable number of X ray installations. Dr. G. W. C. Kaye states in his report that, although occasionally conditions are found which leave very much to be desired, a general trend of progress can be plainly discerned as the result of the Committee's recommendations. The year has been marked by an increase in the number of X ray protective materials and appliances submitted for test, among which have been complete sections of floors, walls, and ceilings of X ray departments. Barium plasters, which are often used as protective coverings for walls of X ray rooms, are found to possess poorer protective qualities at the voltages used for deep therapy than at those appropriate for radiography. A radiographic investigation of these plasters has been made and the results indicate that care should be taken to see that the barium plasters are correctly mixed and that they are applied to the walls of X ray rooms in thickness which allows a fair margin of safety. An important addition to the equipment of the Radiology Department is the apparatus for the ready oscillographic examination of the potential and current wave forms of high tension generators, such as are used in medical radiology. The importance of research on the output of these machines can hardly be over-estimated, and the results obtained with the new equipment will be awaited for with interest. The amount of radium tested during the year has shown a decrease, which, it is suggested, may be due to a smaller demand for radium in this country or to the testing facilities now available in Belgium. The usual method of radium measurement requires that the radium preparation shall be in radio-active equilibrium, which necessitates a period of five weeks between the sealing of the preparation and its measurement. To meet the consequent inconvenience which sometimes arises, the laboratory is now prepared to report on radium preparations before they have reached radio-active equilibrium. Further attention has been given to the development of sound pulse photography in connexion with the acoustics of buildings and some beautiful photographs obtained by this method are given in the report. The means adopted in this work is to photograph the sound generated by an electric spark excited within a model section of the auditorium, the characteristics of which are required. Valuable information about acoustics has thus been obtained. The ripple tank method of studying wave phenomena has been used to ascertain the characteristics of continuously excited water ripples with a view to finding out whether this method allows the determination by analogy of the behaviour of sound waves in similar circumstances. The results compare favourably with those obtained by the method of the electric spark, and they point to simplification in the study of problems in sound. A perusal of the report gives an idea of the variety of the problems dealt with at the National Physical Laboratory. The high standard of accuracy and precision which stamps all its work is a thing of which everyone responsible may be proud.

## MENTAL ANOREXIA.

IN the *Presse Médicale* of March 27th Dr. M. Nathan describes different varieties of what he terms *les anorexies mentales*. Accompanied, but not primarily caused, by digestive disturbances, anorexia occurs as a secondary symptom in the definite psychoses, but is more important as a primary condition, though Dr. Nathan declares that primary mental anorexia does not represent a homogeneous grouping and that too simple a conception of it may lead to disaster. Like most psychoneurotic symptoms, this one becomes, to the careful clinician, only part of a larger picture completed by other symptoms or even abnormal temperamental reactions. Dr. Nathan sketches the anorexia of the adolescent girl who becomes fearful of the approach of puberty; she recovers in 85 per cent. of cases if removed from home surroundings but tends to relapse when faced by later emotional situations. In another variety, exemplified by Breuer's classical case, the anorexia results from a displacement of affect and an emotional reaction that would be adequate to some past event is repeated when the patient attempts to eat or drink; here the psychic reaction is of the nature of anxiety, phobia, or compulsion. Sometimes the symptom represents what Freud calls "the flight into illness," when the patient opposes a strenuous resistance to that therapy which, if successful, would prevent escape from unpleasing reality. Whatever its cause, the anorexia itself calls for treatment, and one general rule is that the patient must be isolated from family and friends. Apart from this measure, therapy varies according to the case, and the writer frankly leaves unanswered his own questions as to how relapses may be prevented and what proportion of so-called simple cases are early states of melancholia or dementia præcox. Dr. Nathan shows how an apparently simple symptom, when approached as a problem in psychopathology, reveals complexities that we are apt to leave out of consideration.

## MOVEMENTS OF THE MANDIBLE.

THE movements of the lower jaw, in the apparently simple actions of opening and shutting the mouth, are somewhat more complex than may be imagined. The structure of the joint, which contains an inter-articular cartilage and double cavities, suggests this in itself. The mandibular condyles do not rotate in the glenoid cavities, but round an axis running transversely at a much lower level. Some have even maintained that this axis passes through or near the angle of the jaw, but observation will show that the angle moves back almost as much as the condyle moves forward when the mouth is opened, and there seems to be a general agreement among observers that the axis of rotation goes through the lingula or inferior dental foramen, roughly about halfway down the ramus. Here is the raison d'être of the two cavities in the joint; the condyle, moving forward, must rotate within the concavity of the meniscus, which is therefore drawn forward with it, and the upper joint cavity allows of this sliding of the inter-articular cartilage on the temporal bone. Any interference with the freedom of either of these cavities will affect the complete movement, for the freedom of action of both of them is necessary, and one by itself is of no use. With these facts in mind, it is interesting to turn to an account of the action and strength of the muscles concerned in jaw movement, such as that given by Mr. Sheldon Friel in the April issue of the *British Dental Journal*. Mr. Friel, reporting on the use of the Dental Board's facial and jaw dynamometers, gives short descriptions of the results he obtained with these ingenious instruments, and considers them from the orthodontic point of view. The static functions of the muscular cheeks and lips, and of the tongue, with which he also deals, are of importance to orthodontists, and we look forward with confidence to further expansion and investigation in this line of research.

## THE SUPERIORITY OF THE NON-SMOKER.

A FEW weeks ago we set out a German view of nicotine recalling Prof. H. Kionka's statement that there is hardly a single pathological condition which tobacco cannot cause or aggravate. But, considering the universality of the smoking habit and the large number of heavy smokers, Sir Humphry Rolleston is certainly within the mark in regarding as remarkable the comparative rarity of undoubted lesions due to smoking. In his address, which we print on another page, he touches on the still more difficult question of the influence of smoking on the higher intellectual centres. In America wide credence has been given to the results of psychological tests on medical students which have demonstrated a lowering of mental efficiency in a percentage of smokers varying from 10 to 25. Sir Humphry Rolleston himself admits that abuse of tobacco may be a contributory factor in neuropathy, although more often no doubt it is the other way round and the constant smoking is a manifestation of neuropathic constitution. We print this week also a continuation of Dr. Rosslyn Earp's studies of the differences between smokers and non-smokers at Antioch College, Ohio, U.S.A. (see p. 1018), which again show a superiority of scholarship achievement among the non-smokers, although in intelligence—so far as this is measured by the mental tests used—the balance is slightly in the other direction. In a note on Dr. Earp's previous paper[1] we suggested that the greater success of the non-smokers both in athletics and in scholarship might be explained by the habit of many athletes of not smoking during training, coupled with an association between good physical and good mental equipment. In reply to this, and apart from the data given in his paper, Dr. Earp tells us that he asked all the Antioch non-smokers why they did not smoke; 50 per cent. of them gave no definite reason, but of the others only two gave a reason in any way connected with athletics. To test an opinion given by one student that the athletic group in American high schools tends to be the fast-living and smoking group, Dr. Earp investigated the relative frequency of school and college "letters," or "colours," as we should call them, and found that—

Of 177 smokers in 1925—
21 have college "letters,"
74 got "letters" at school.

Of 176 non-smokers in 1925—
21 have college "letters,"
56 got "letters" at school.

By this criterion the non-smokers show no athletic superiority. We admit that so far as the Antioch students are concerned our hypothesis of non-smoking for the sake of training does not appear to be correct, but we would still maintain—and we think Dr. Earp will agree—that the facts so far brought forward do not justify any definite conclusion as to a *causal* connexion between the use of tobacco and lower mental or physical achievement.

## VARIATIONS IN FILTERABILITY OF THE ROUS FOWL SARCOMA.

THE sarcomata affecting fowls differ from mammalian malignant new growths in one particular. They are transmissible to other fowls by the inoculation of cell-free filtrates, whereas attempts to propagate tumours from rats or mice in this way have hitherto failed. In a communication to the current number of the *British Journal of Experimental Pathology* W. E. Gye and C. H. Andrewes suggest that the fowl sarcomata would be universally accepted as typical highly malignant neoplasms had this property of filterability remained undiscovered. It seemed, therefore, important to study this property, to determine how far it is constant and to investigate the conditions under which it varies. The technique of preparing a filtrate is set out in detail. If the optimum proportion of diluting fluid is added to the tumour emulsion, which has been pounded in a mortar with sand, the process of obtaining 10 c.cm. of filtrate by a two-stage process should take less than an hour. Filtrates through Chamberland $L_2$ or Mandler candles, when examined with the dark field apparatus, are optically almost empty; occasional particles are seen, but they are very rare. Under the ultra-microscope immense numbers of particles are revealed. The experimental results of the inoculation of filtrates into Plymouth Rock chickens are curiously variable. It is difficult to obtain precise comparisons between filters because of the great variability in the properties of candles; one candle of the same grade may differ from another very considerably in rate of filtration and in infectivity of filtrate. It is evident, however, that filter candles absorb a large part of the agent—or agents—which cause the fowl sarcoma. But the virulence of filtrates from different tumours also varies, so that 1 c.cm. of filtrate through a Chamberland $L_2$ candle is sometimes as effective in inducing a tumour as is 1 c.cm. of the coarser candle ($L_1$) filtrate. These differences were attributed for a long time to inevitable variations in biological experiments, and to differences in filter candles, choice of tumour material, and so forth. Further investigations, however, proved that an individual tumour may vary in its filterability. On July 7th, 1925, a tumour produced a month previously by the inoculation of 0·1 c.cm. of a Mandler filtrate was taken and minced, a bird being inoculated with 0·1 c.cm. of the cell emulsion. The resulting tumour grew, but very slowly. The Mandler filtrate from this tumour was not infective. The tumour was passed by cell inoculations through

---

[1] THE LANCET, 1925, i., 194.

14 successive birds, the growth being tested in each generation as to its power of inducing tumour formation with cell-free filtrates. For six months, covering some 12 passages, the filtrates were non-infective. At the end of this time the histological structure remained constant, except that the bundles of spindle cells were more compact. Metastasis formation was infrequent and the hæmorrhagic points and masses commonly seen in metastases of this tumour were absent. Further, the tumour suffered a loss of proliferative power, became relatively benign, and showed fluctuations in growth energy similar to those characteristic of mammalian transplantable tumours. In February, 1920, the tumour again altered its character, forming (in chicken No. 72) a large, soft hæmorrhagic growth with internal hæmorrhagic metastases; 1 c.cm. Mandler filtrate of this tumour killed a bird in 15 days. Filterability had therefore returned. While these experiments were in progress, another readily filterable strain of the tumour, recently obtained from Dr. Peyton Rous, was being carried on; this seemed to exclude the possibility that the results recorded above could be explained by any variations in technique. The authors conclude that the property of filterability is variable; it is not fixed and unalterable like the microscopical anatomy of the tumour. The explanation of this sudden disappearance and reappearance of filterability has not yet been determined; but in view of these findings, the presence of this property can hardly be taken to constitute a fundamental difference between the Rous fowl sarcoma and other transplantable tumours.

# The Services.

## ROYAL NAVAL MEDICAL SERVICE.

THE following appointments are notified:—Surg. Comdr. H. B. Parker to the *President*, addl., for R.N. Medical School, Greenwich. Surg. Lt.-Comdrs.: R. Lyon to the *Constance*; L. S. Goss to the *Colombo* (on exchange); R. A. Brown to the *Vivid*, for R.N. Hospl., Plymouth; J. M. Horan to the *Broke*, to be accommodated in Whitshed; L. R. Warburton to the *President*, addl., for three months' post-graduate course and H. L. Douglas to the *Pembroke*, for Sheerness Dockyard (temp.). Surg. Lt.: J. Cussen to the *Colombo*.

A. S. Bradlaw to be Surg. Lt.

## ROYAL ARMY MEDICAL CORPS.

Lt.-Col. C. Clarke, R.A., Res. of Off., to be Maj. whilst re-empld., and relinquishes the rank of Lt.-Col.

Capt. H. G. Dressing, R.A., Res. of Off., is re-empld.

Lt. (on prob.) T. A. J. M. Dodd from the secd. list is restd. to the estabt.

### SUPPLEMENTARY RESERVE OF OFFICERS.

Lt. A. S. Burns resigns his commn.

### TERRITORIAL ARMY.

Lt. P. Hayes to be Capt.

Sanitary Companies.—Capt. H. C. Sands to command 6th (London) Sanitary Company.

## ROYAL AIR FORCE.

Flying Officer G. P. O'Connell is promoted to the rank of Flight Lt.

Flight Lt. J. D. Woodrow is transferred to the Reserve, Class D. 2.

## INDIAN MEDICAL SERVICE.

The King has approved the retirement of Lt.-Col. W. H. Tucker on account of ill-health.

## DEATHS IN THE SERVICES.

Lt.-Col. Edward Hearne Joynt, R.A.M.C., who died at his residence at Blackheath on April 27th, aged 79, graduated M.D., M.Ch., in the Royal University of Ireland in 1870, and obtained his first commission in the Army in 1871, reaching the rank of Lt.-Col., R.A.M.C., in 1891 and retiring with that rank in 1902. He served in the Soudan in 1885–6 and also with the Frontier Field Force (medal and bronze star). In 1895 he was senior medical officer at Kingston, Jamaica.

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

## CLXXIII.—THE TREATMENT OF SCIATICA.

THE term sciatica properly denotes an inflammation of the interstitial tissue of the sciatic nerve or its roots. Unfortunately, the word is often used loosely, and for this reason it must be emphasised that the methods of treatment described below are applicable only to the true sciatic neuritis, and that the first essential for their successful employment is accurate diagnosis. Most diagnostic errors will be avoided if it be remembered that (1) in sciatica the inflamed nerve is always tender; (2) since the sciatic nerve sends no branches to the front of the thigh, any condition in which the pain extends to the front of the thigh or groin is not sciatica alone; (3) sciatica causes no muscular paralysis and no gross sensory loss; (4) it may abolish the ankle-jerk but never the knee-jerk. When sciatica is associated with arthritis of the hip, treatment should first be directed to the latter.

### LOCAL TREATMENT.

There are four or five methods which may give early and rapid relief, if not complete cure, the choice depending on the severity and on the stage of the ailment. With all of them the general principles which govern the treatment of inflammatory conditions must be practised. The patient must be kept at rest in bed and heat in some form should be applied to the affected limb; for this purpose thermogene or other warm wool stitched loosely into a rather tight-fitting garment so as to cover the hip and outer part of the thigh will be found convenient. Generally speaking, it is not desirable to splint the limb, for the patient will wish to move in bed. The bed, for his comfort, should be as soft as possible.

### *Electrical Methods.*

(*a*) *Anodal Galvanism.*—The treatment by galvanism is less used now than formerly, having to some extent been ousted by methods of injection. Small currents are useless, and the provision of a current of at least 20 milliamps necessitates a large and unwieldy battery, or else a pantostat, either of which it is troublesome to take to and from the patient's own home. But if the patient is in a hospital or nursing home, galvanism in my opinion is still the method of choice for mild or moderate cases.

A current of 20 milliamps passed from the buttock along the back of the thigh for 20 or 30 minutes daily—or, if possible, twice a day—has a very soothing and beneficial effect. Proper precautions must be taken to avoid burns and painful shocks; it is essential that large electrodes be used and that they be well padded and wetted; the anode should be at least six inches by four, the cathode at least twice that size. The anode is tightly applied to the buttock of the affected side and the cathode to the back of the knee. When the electrodes are in position the current is started and gradually increased until the required current is passing; as the patient's resistance will diminish the ammeter must be watched, the current kept approximately at the assigned strength for the duration of the sitting, and then gradually reduced to zero before the wires are disconnected.

Galvanism may be combined with ionisation (the position of the electrodes then being reversed), but I am doubtful whether anything is gained by the addition, and the danger of skin troubles is increased. The direct application of electrolysis to the nerve has been favourably reported on by Dr. E. A. Goulden, but I have no experience of this treatment.

(*b*) *Diathermy* provides a comforting, warm, inward glow which may be most soothing to the inflamed sciatic nerve. It is suitable for the same kind of case and under the same circumstances as galvanism, and it is applied through large wet pads placed one on the back and one on the front of the thigh.

### *The Use of Oxygen.*

Two or three years ago the procedure of injecting oxygen into the subcutaneous tissues of the affected limb was introduced into this country. This method of treatment is suitable for acute and subacute cases, and though it may be somewhat uncertain, its extreme simplicity makes it always worth trying.

To a small oxygen cylinder fitted with the usual tap a short piece of rubber tubing is attached; it leads by means of a tapering glass connexion to a piece of light tubing of narrow bore, and, for convenient manipulation, about four feet in length. The tap of the oxygen cylinder is opened slightly, the end of the fine rubber tube is placed in a tumbler of sterile water, and the oxygen flow regulated till the bubbles are rising at the rate of about ten per second. The tube is withdrawn from the water and a sterilised hypodermic or Record needle is attached to the end of it. The needle is inserted just through the skin over a painful part of the limb and the oxygen immediately begins to infiltrate the subcutaneous tissue. If the flow of oxygen be too strong the rubber tubing will blow off the needle when the injection is begun. Injection is continued at the same spot as long as the infiltration continues to extend freely and until all the surrounding area is well ballooned up. Then the needle is withdrawn and a second injection is made elsewhere. It is sufficient to balloon the thigh and buttock at one sitting and either the same region or the leg a few days later. The subcutaneous emphysema spreads somewhat after the injection has ceased and it lasts, as a rule, two or three days. When it has gone the same area may be re-injected. Two or three injections often give the most surprising relief; this technique and the injection of a small amount of novocaine into the nerve sheath enabled a ballet-master, who had been tied by the leg to his bed in London, to start training a ballet in Paris 14 days after treatment was begun.

The way in which oxygen acts in these cases is not known, but the mechanical action in providing a cushion within the limb is probably a factor. It is likely, too, that the oxygen has a favourable effect on the inflammation in the fibrous tissues, and that by penetrating among them and loosening them it separates small inflamed surfaces and breaks down many minute adhesions.

### *Injections of Saline.*

One of the most reliable methods in the treatment of sciatica consists in the injection of two to four ounces of normal saline solution into the sheath of the nerve. This is the method of choice in a case which has persisted unabated for a month or six weeks, and its object is, by distending the sheath, to relieve pressure on irritated nerve-fibres and to break down adhesions which are tending to make the sciatica chronic.

The injection is usually made either at the level of the ischial tuberosity, where the nerve, as it emerges from under cover of the gluteus maximus, is comparatively superficial, or in the middle of the buttock, where the nerve has just left the sciatic notch. The course of the nerve at the lower level can usually be determined by the line of tenderness and can be marked on the skin. A small area of skin lying on this line having been anæsthetised by 2 per cent. novocaine solution, a needle about four inches long is entered vertically as the patient lies on his face. The depth at which the nerve is encountered varies considerably with the build of the patient, but the patient knows when the needle touches the nerve, and the physician may sometimes feel the resistance of its sheath. I prefer at this stage, following Wilfred Harris's technique, to inject a single cubic centimetre of saline. If the patient experiences a thrill passing down to the heel or calf, one knows that the point of the needle is within the nerve sheath; if he experiences no such sensation the needle may have passed through the nerve. When one is satisfied that the point is within the nerve sheath, 2 c.cm. of the novocaine solution are injected slowly, and when the pain has ceased and the leg feels numb, three or four syringefuls of warm (104° F.) sterile normal saline are injected with a 20 c.cm. Record syringe.

The patient should be kept in bed for a day or two and a Dover's powder (15 gr.) should be given on the first night to allay restlessness and discomfort. A second injection may be given after five or six days. If the chief pain is in the buttock, it is well to give one of the injections as high up the nerve trunk as possible—i.e., just below the sciatic notch; there the nerve may not be so easily found by the needle as it is at the lower border of the gluteus maximus.

### *Epidural Injection of Antipyrin.*

None of the methods of treatment hitherto described are successful when the site of inflammation is in the roots of the sciatic nerve, and for cases of this kind injection into the epidural space within the sacral canal was devised. Though the dura extends down as far as the middle of the sacrum, it lies anteriorly in the sacral canal, and, by means of a needle passed upwards through the sacro-coccygeal ligament, substances can be injected around it and made to bathe the nerve roots as they emerge from it. The substance which has hitherto been the most successful is a concentrated (40 per cent.) solution of antipyrin, the use of which was introduced by Dr. F. Högler, of Vienna, in 1922. The technique is not difficult.

The patient may be prepared by an injection of half a grain of morphine half an hour beforehand, for the distension of the epidural space is often attended with considerable pain. He places himself in the knee-elbow position. The appropriate area of skin having been well rubbed with iodine and anæsthetised with novocaine, a needle, four or five inches long, is inserted in the middle line one inch above the top of the natal groove, pointing headwards at an angle of 60 degrees to the horizontal; it impinges on the sacro-coccygeal ligament, a firm elastic structure which is easily distinguished from bone by the sensation conveyed by the needle to the fingers. The needle is passed through the ligament and then its direction is at once changed, so that it lies parallel to the sacral canal. It is pushed cautiously up the canal for two inches or more in the middle line; if one deflects from the middle line at this stage the needle may encounter a nerve-root and cause the patient a sharp pain. Cerebro-spinal fluid should not be seen, for its appearance would indicate that the dura had been penetrated. The point of the needle once in position may be deflected a little towards the affected side, and then, by means of a Record syringe, 10 c.cm. of warm antipyrin solution are slowly injected. Some resistance may be met with and the solution should be forced in slowly; if pain is caused, it lasts only while the resistance is actually being overcome. When the needle is withdrawn, the skin opening is closed with collodion and the patient then lies on his affected side for at least an hour. By that time he is usually free from any actual pain, though he may have a little discomfort in the sacrum or buttock. Some pain almost invariably occurs on the third day afterwards, but it only lasts 24 hours and is easily relieved by rest and aspirin.

While primarily adapted for root sciatica, this treatment is almost equally successful when the inflammation is in the stem. In my experience (six cases), though complete freedom from pain may not be secured, the great merit of the method is that it removes the crippling element and enables the patient to walk and to move freely in bed within a few hours. Högler sometimes gives a second injection after a week's interval, but I have hitherto found galvanism sufficient when supplementary treatment has been required. This method is applicable in the acute stage of sciatica and may give good results even in cases of long standing.

### *Surgical Methods.*

There are occasions when it may be well to expose the nerve in cases of sciatica; stretching it with the finger may do good at almost any stage of the illness and longitudinal incision of the sheath may give relief, though for different reasons, both in the acute and in the very chronic case.

## GENERAL TREATMENT.

In the early stage the first essential is, with the aid of simple hypnotics, to secure sufficient sleep for the patient in order that he may not become exhausted. During the day the pain should be relieved by liberal doses of aspirin. As soon as the acute phase has subsided, whether local treatment has been given or not, the patient should have a general tonic; calcium lactophosphate will be found suitable. Debilitating factors such as infective foci, glycosuria, or albuminuria should be sought for, and constipation should be carefully treated. Removal of the teeth at this period is not to be recommended; if the patient has pyorrhœa their extraction may be advisable later, but the first effect of edentition is debilitating, and at a time when the patient is just recovering from an acute illness and requires plenty of nourishment palliative measures are more satisfactory.

J. P. MARTIN, M.D., M.R.C.P.,
Assistant Physician, National Hospital, Queen-square.

## OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

### ANNUAL CONGRESS, APRIL 29TH–MAY 1ST.

THE annual congress took place at the house of the Royal Society of Medicine on April 29–30th and May 1st, Sir JOHN PARSONS presiding.

### *President's Address.*

Sir JOHN PARSONS devoted his address to a consideration of the progress of ophthalmology and the part played in this by this body, as well as what it might hope to achieve in the future. Advances in biology must of necessity lag behind those in physics and chemistry, seeing that biological processes depended fundamentally on physico-chemical processes, a fact grievously neglected by most psychologists. Ophthalmology could be regarded as a branch of biology. Medicine was now gradually emerging from the dominance of empiricism and metaphysical speculation, but, owing to the fundamental constitution of human nature, it could not be expected ever to rank as a pure science. Medicine dealt with the preservation of life, more important even than the acquisition of wealth, hence the tendency to take short cuts in medicine. Yet there was no royal road to scientific certitude. Confronted with disease, man's eagerness to get well led him to clutch at any straw, and he was still under the subtle witchery of the quack and the charlatan. Against this quackery it was the duty of the Society to wage war, though without self-glorification, for there was an empiricism which was legitimate in the practice of medicine. The distinguished names the Society had included, and the 45 volumes of its transactions, showed how well the proper functions of a medical society had been fulfilled; it had kept abreast of the times and fostered research. Still it was possible that sometimes too narrow a view of the scope of ophthalmology had been taken, and that it did not sufficiently include observation of the ways in which ophthalmology impinged on public life, and how advances in other sciences could be applied to this.

Among the efforts to better the working community there of necessity arose ophthalmic problems, such as those concerned with illumination and fatigue, only few of which could be solved without research. He referred to the labours of the Medical Research Council, especially in regard to the legibility of types, the effect of flickering lights, light therapy, and the effects of illumination in industry, the latter in association with the Department of Scientific and Industrial Research. As there seemed a difficulty in finding sufficient workers qualified to undertake these researches, Sir John Parsons appealed to members to encourage clinical assistants and others to equip themselves to carry on this class of work. A good example of his meaning was afforded by the effect of light therapy in certain disease conditions. That ophthalmology was a narrow and sharply delimited field of work was a view which was supported by the average text-book and curriculum, but it was fundamentally erroneous. As a receptor organ, it could only be adequately studied as an integral part of that varied receptor apparatus which was the gateway of perception. The average ophthalmologist seemed content to acquire only the rudiments of optics. Adequate stimuli to the eye included wave-lengths possessing peculiar and often deleterious properties when applied to living tissues, especially such delicate ones as those of the retina. A warning of the potency of these stimuli was needed, especially at a time when light therapy was being applied by practitioners who were ignorant of the properties of light.

It was, he continued, lamentable that the pretensions of a relatively small but influential group of sight-testing opticians should preclude ophthalmologists from taking part in collaborating with those who were devoting their lives to optical investigations. Still the problem presented by the sight-testing optician was not insoluble. Stimuli impinging on receptor organs set up nerve impulses, and there was evidence that these nerve impulses were the same in type, whether they originated in the eye, in the skin, the muscle, or the central nervous system, and ophthalmology should take cognisance of them all. The bane of specialisation was isolation, and its cure was coöperation, and he hoped the Society would continue to contribute worthily to the repair and improvement of the great edifice which was erected by its predecessors and had been entrusted to the care of its present members.

Prof. H. E. ROAF gave an address entitled

### *Some Observations on Colour Vision.*

In an attempt to investigate the way in which radiant energy was transformed into nerve impulses, he set himself to endeavour to understand in what way colour vision was related to the wave-length of light. It was necessary to search for some kind of differential apparatus in the retina, and he set a colour-blind person to copy a coloured diagram by using an ordinary box of paints. By looking through a blue glass one could not distinguish the difference oneself, hence the view obtained was that of a colour-blind person. He examined 28 cases, and found that in all of them the defect was in the red end of the spectrum. Pigments reflected mixed light, and by cutting out the red end of the spectrum most of the mistakes disappeared. Unless radiant energy was absorbed it would not stimulate the nerves, though it did not follow that all the light absorbed would stimulate. He thought that, on the analogy of chlorophyll synthesis in plants, the colour function might be sought in the cones of the human eye. In the cones of birds, reptiles, and amphibians there were coloured globules, situated at the junction of the cone and the cone body. Birds had cones which would perceive red light only, and cones which perceived red and green, and Prof. Roaf proceeded to elaborate his idea that colour-blindness was due to a deficiency of pigment in minute globules. He thought there might also be a good deal to be said for varying degrees of sensitivity of the eye to different colours. His studies were still in progress.

Dr. GEORGE MACKAY (Edinburgh) gave a résumé of the work of Schaaff, of Strasbourg, which was somewhat on the same lines as that done by Ishi-Hara. Dr. Mackay himself raised the question whether colour perception rested with the retina at all, suggesting the likelihood that it was a function of the nerve cells in the cerebral region. For instance, hæmatochromatopsia was a definite condition which occurred without serious impairment of the form sense, and might take place purely as the result of a delicate occipital lesion. He proceeded to discuss the theory just advanced by Prof. Roaf.

The PRESIDENT drew attention to the variation in the intensity of the colours in books reproduced by lithography according to the stage of the impression struck off. The trichromatic hypothesis was a useful one for the understanding of colour vision.

Mr. RAYNER BATTEN read a paper in which he emphasised the value of collective drawings of diseases of the fundus as an aid to research, and showed a large series of coloured drawings made by Messrs. Hamblin. He suggested that it would be well to have a curator responsible for these.

Mr. TREACHER COLLINS, Mr. ERNEST CLARKE, and the PRESIDENT spoke favourably of the idea.

Mr. GEORGE YOUNG (Colchester) read the account of a case under his care, the subject of chronic glaucoma, in which, though the vision had become reduced to perception of hand movements, it became restored to normal with a correcting lens. At one stage it looked as if recovery would be impossible.

### *Intra- and Extra-ocular Melanomata.*

Thursday afternoon was devoted to a discussion of this subject. It was opened by Mr. G. W. SPENCER, Dr. ARTHUR WHITFIELD, and Mr. TREACHER COLLINS.

Mr. SPENCER said that the melanotic pigment, melanin, was now recognised not merely as a side product of an infrequent variety of cancer, but as being directly connected with disturbance of cell metabolism. At first localised to special cells, and apparently benign, it later took an integral part in the development of cancer. Extra-ocular melanomata had the general characters of those of the skin, and were amenable to the same treatment—namely, excision before the onset of malignant disease. Intra-ocular melanotic disease was beyond the control of surgery, and removal of the affected eyeball did not prevent the patient ultimately dying of generalised cancer.

Dr. WHITFIELD entered into the histology of these growths in the skin, and discussed the earliest detectable changes, which he considered to be at the bases of the interpapillary epithelial ridges. He said the solution of epithelial fibrils and the isolation of cells was coincident with the appearance of intra- and inter-cellular pigment. He did not consider that pigment production was an essential in nævus. When a mole was removed and submitted for an opinion as to whether or not it was malignant it was often very difficult to be positive.

Mr. COLLINS showed by the epidiascope a series of drawings of intra-ocular melanomata, both innocent and malignant. He said he considered that, in the normal tissues of the eyeball, melanoblasts were both epiblastic and mesoblastic in origin, and that in the iris innocent melanotic growths could arise from both those forms of tissue. Innocent mesoblastic melanomata might be either localised or diffuse and were a hyperplasia of the surface endothelium, or a formation of clump cells, or both combined. Malignant growths might start from these innocent ones, and consisted of spindle-shaped cells and clump cells. Metaplasia of endothelial cells into spindle-shaped cells took place both in the normal development of the eye after traumatic lesions and in connexion with malignant neoplasms. Malignant melanotic epithelial growths might, in rare instances, originate in the pigment epithelium of the ciliary body, possibly also from the pigment epithelium of other portions of the uveal tract.

The discussion was continued by Mr. AFFLECK GREEVES, Mr. R. FOSTER MOORE, Dr. HOUWER, Mr. RICHARDSON CROSS (Bristol), Mr. R. C. DAVENPORT, and Mr. C. H. USHER.

On Friday morning Mr. J. H. TOMLINSON contributed a note on the comparative brightness values of the two eyes and a single eye, which followed a contribution by him on the subject some years ago. His conclusion was that the two eyes together had an advantage over one eye in the proportion of 115 to 100.

### *The Value of Ultra-violet Light in some Eye Diseases.*

Mr. C. B. GOULDEN, in a paper on this subject, said that ultra-violet light seemed to have provided a means of curing one of the disastrous diseases of the eye—namely, tuberculosis of the iris and ciliary body. It did not seem to produce benefit in a number of other conditions, such as episcleritis, sclerosing keratitis, chronic irido-cyclitis. He described the technique of the applications.

Mr. W. S. DUKE-ELDER read a paper on the same lines, and detailed the procedure being adopted at the Royal London Ophthalmic Hospital. He agreed with everything advanced in Mr. Goulden's paper, and entered into a consideration of the thermic and electro-chemical reactions produced by the rays. He said the chronic blepharitis seen in sun-starved city children yielded well to ultra-violet irradiation.

The PRESIDENT spoke of extraordinary benefit which resulted in a most stubborn case of his own, of irido-cyclitis with keratitis punctata, following treatment in this way by Mr. Duke-Elder.

Dr. W. O'DONOVAN, speaking as a skin physician, supported all that had been said, the remarks being equally applicable to tubercle—particularly lupus—of the skin.

Mr. M. S. MAYOU gave a careful account, supported by some beautiful slides, of siderosis bulbi; Mr. R. DAVENPORT read a communication on senile macular exudative retinitis; and Miss MARGARET DOBSON submitted one on morbid change in the macular region as seen by red-free light.

### *Clinical Demonstration.*

At the demonstration and discussion of numerous clinical cases at St. Bartholomew's Hospital on Friday afternoon, arranged by Mr. Foster Moore, an interesting expression of opinion took place on the application of radium to rodent ulcer. Mr. Foster Moore showed a young woman who, when she came under his care, had been having radium treatment for rodent ulcer of the inner canthus of the eye. He cut away the disease as freely as he was able, but found it had involved the ethmoid and had bored into it. Six months ago there were evidences of regrowth, and he now asked advice of members as to whether the orbit should be exenterated. The pathological report was that it was rodent, not epithelioma. His own experience of the treatment of rodent ulcer by radium was unfortunate, for though the surface growth became smaller, penetration seemed to go on in spite of the application, as happened in this case. Radium should only be applied as a last resort.

Mr. GOULDEN said his experience of the treatment of this condition by radium agreed with the exhibitor's. Often the surgeon's aid in these cases was not sought until eye movements were defective, by which time the orbit had usually become invaded, with involvement of the nasal bone, the ethmoid, the floor of the frontal sinus, and the roof of the maxillary antrum. He described a recent case in which he operated in conjunction with the aural and nasal surgeon, a practice he recommended.

Mr. HARRISON BUTLER spoke of three fairly recent cases of rodent ulcer in the eye region which were treated by radium, and seemed to improve for a time, but all were now dead.

Mr. MALCOLM HEPBURN strongly advised that this patient's orbit be eviscerated in order to preserve life.

Mr. GREEVES agreed with Mr. Hepburn; it would be useless to try to remove this growth if the retention of a useful eye was aimed at, and the eye ought to be sacrificed.

The PRESIDENT expressed his agreement with the views which had been given; to think that rodent ulcer could be cured in this way was very fallacious, and he was always disappointed to have at his clinic a case of rodent ulcer which had already been subjected to radium.

Among the other cases was one of dermoid of the orbit, which, when removed, was found to contain a fairly fully developed tooth; also two cases of Eales's disease in brothers.

The Friday evening session was given up to a discussion on

### *Birth Injuries of the Eye.*

Dr. COMYNS BERKELEY, in opening, said his 30 years' experience led him to believe that injuries to the eyes caused as a result of labour were very rare, though he did not examine infants' eyes with the ophthalmoscope. Still, various writers had given varying proportions for such injuries.

Mr. ERNEST THOMSON said it was possible to overlook many birth injuries of the eye, and the ophthalmic surgeon should constantly have in mind the possibility that certain eye conditions seen in later life might have been due to damage sustained at birth. Retinal hæmorrhage was by no means infrequent, and he thought a series of new-born infants should be examined for these, to see in what proportion they occurred.

Dr. LESLIE BUCHANAN spoke chiefly of the injuries which indirectly affected the eye, and entered into a consideration of these in considerable detail.

Mr. F. A. Juler, Mr. A. W. Ormond, Mr. J. Rowan, Mr. Treacher Collins, Dr. A. J. Ballantyne, Mr. Harrison Butler, Dr. T. H. Whittington, and the President also took part in the discussion.

On Saturday Mr. A. F. MacCallan and Miss Ida Mann read communications on papilloedema and choroido-retinitis in a pedigree bull, the former on the appearances seen during life, and the latter on the histology.

Mr. E. Fincham demonstrated and described his slit-lamp, and showed slides of the structure of the retina, which the President said were the most beautiful sections he had ever seen. Mr. Fincham also submitted some observations on the accommodation of the eye.

After a meeting of British ophthalmologists a party journeyed to the National Physical Laboratory, at the invitation of Sir Joseph Petavel, the Director, and inspected its various departments. On Thursday evening members dined together, and during the three days of the Congress a fairly extensive exhibition of instruments and apparatus used in the specialty was held in an adjacent room, including slit-lamps, amblyoscopes, and synoptiscopes.

## A CONGRESS ON HYDROLOGY IN CZECHO-SLOVAKIA.

The annual meeting of the International Society of Medical Hydrology, under the presidency of Dr. Gustave Monod and subsequently Dr. Mougeot, has taken place this year (April 15th–22nd) in Czecho-Slovakia, following invitations received from the Czech Government and Spa Municipalities. Representatives of 13 countries were present at the various meetings, the party numbering about 60 persons. The British contingent, 28, included two from the Ministry of Health, Sir T. Horder, Sir W. Willcox, Sir H. Waring, and Prof. D. Stanley, of Birmingham University, as well as Mr. W. A. Appleton and Mr. Izard, of the Federation of Trades Unions and the Prudential Approved Societies. For the unfailing and varied interest of the tour, its smooth organisation and comfort, cordial acknowledgments are due not only to Dr. Schmidt and Dr. Porges (the representatives of the Society in Czecho-Slovakia), but to the authorities in Prague, the Legation in London, and especially to Dr. Driml, who conducted the party through the country as representing the Czech Ministry of Public Health.

At Karlovy-Lazne (Karlsbad), Marianske Lazne (Marienbad), and Frantiskovy Lazne (Franzensbad) the Society was received by the burgomaster and the medical societies, and after a formal meeting in each place entertained to dinner. At Karlsbad Dr. F. Kraus discussed the pharmacology of sulphate of sodium waters, and Drs. Hermann, Glénard (Vichy), and Roubischek the treatment by waters of disorders of the liver, Dr. Kampe giving a lantern demonstration on the geology and history of the springs. From Karlsbad a visit was paid to the highly radioactive waters of Joachimsthal, now one of the State spas, where Drs. Stauch and Tommanec gave interesting discourses on the work done there and in the radium laboratories at Prague. At Franzensbad papers were read on the action of effervescent baths by Drs. Selig and S. Wasserman. Prof. Zörkendörfer, director of the Institute of Balneology at Marienbad, who is charged with the oversight of the springs and mineral waters, met the party at Franzensbad. His clear and illuminating demonstrations, given in the open air at the various sources and on the moor, and subsequently in his institute at Marienbad, will long be remembered by those who heard them. After arrival, with aeroplane escort, at Marienbad, a meeting of the Society took place for discussions (1) on glandular insufficiency and spa treatment, by Dr. Porges, Prof. Loewy, and Dr. Hans Kopf; (2) hypertonia and its treatment, by Drs. Pflanz, Guillaume (Spa), Mougeot (Royat), Schober (Wildbad), and others.

From this point, and for the remainder of their journey, the party were given a special train with sleeping cars and proceeded to Prague for an official reception and luncheon. The Society and its guests were received at the Municipal Hall by representatives of the Ministries of Public Health and Education and the burgomaster, Dr. Baxa. Prof. Kulhavy was present on behalf of the Section of Public Health and of the medical faculty of the Czech University, Prof. Coury for the German University, and Dr. Mladejovsky, who is professor of balneology in the Czech University at Prague, for the Central Association of the Czecho-Slovakian spas. Others present were Dr. Hrdlicka, who represents Czecho-Slovakia in the Health Department of the League of Nations, Dr. Moravek, director of the State spas in the Ministry of Public Health, and Dr. Procharzka, city health officer. After luncheon visits were paid to some of the more remarkable places in this ancient and beautiful city, including the great sanatorium for paying patients under Dr. Jedlicka.

At Pistany, a hyperthermal spa on the borders of the mountains in Slovakia, the congressists were met on behalf of the prefecture, the local medical society, and Mr. Winter, proprietor of the spa. The remarkable Irma Bath Establishment and the Pro Patria Hospital were visited. At the hospital, where insured persons suffering from rheumatic affections and injuries are under treatment by mud baths, Dr. Reichart gave an interesting demonstration of the technique employed in these baths. Particular interest was shown in the methods used for "heart cooling" during thermal and hyperthermal applications. The circulation of cold water through a coiled Leiter's tube applied to the cardiac region is here used in order to prevent the distress, fatigue, and tachycardia which often attend or follow such applications of heat. By this means the necessary thermal treatment is often made possible for weak or sensitive persons, and debilitating after-effects are avoided.

Two discussions of considerable interest took place at Pistany. The first, on the actions and therapeutic uses of mud baths, was introduced by Drs. Schmidt and Reichart of Pistany. Profs. Vinaj, Di Tommasi, and Piccinnini described similar treatment in Italy—at Abano, Agnano, and Salso-Maggiore—and Drs. Fodor (Vienna), Schober (Wildbad), and S. Wasserman (Franzensbad) followed. Dr. Schmidt, with Strasser and others, suggests that the modus operandi of heat, especially in local applications like the Pistany packs of hyperthermal mud, is actually a resolution and reabsorption of extravascular exudations. The passage of these "foreign" proteins into the blood stream is in effect an auto-inoculation, such as commonly occurs in tuberculosis, with effects analogous to those of protein shock. In any case great local activation of the blood and lymph circulation is produced in these baths, and all speakers were agreed that this local action was beneficial in many chronic rheumatic conditions. Care was, however, necessary to avoid debility, and emphasis was laid on the need for rest after such baths, of which visitors to Pistany are reminded by the carrying chairs or rickshaws standing outside the bathing establishments. After luncheon a lantern exhibition of the history of the spa was given by Dr. Paul Veres. The evening was occupied by an international discussion on the ætiology and treatment of chronic rheumatic affections (vide infra).

The last day was spent in the Tatra Mountains. Starting from Tatranske Lomnica, the party visited Dr. Guhr's sanatorium (c. 4200 feet) at which many cases of exophthalmic goitre are treated by physical methods, and afterwards the Palace Sanatorium at Novy Smokovec (3300 feet), where anæmia, debility, and catarrh, as well as tuberculosis, are treated by sunshine, cool mountain air, and graduated exercise and rest. Dr. Szontagh, the medical director, gave a short account of the treatment of exophthalmic goitre in the Tatra Mountains. A great factor was rest and almost monastic quietness. The place was sheltered from the north and surrounded by pine woods. The air was cooling and sufficiently rarefied with little wind. Another essential feature was the application of cold snow-water in bags over the region of the heart for one hour two or three times a day, changing the water when it became warm. Many cases were referred to the Tatra Mountains and returned to work after three to six months.

At the luncheon in the sanatorium at the end of the tour, Dr. Fortescue Fox expressed the pleasure with which the Society had studied these natural resources of Czecho-Slovakia.

In the course of these meetings Dr. Monod was elected for a second year as president; 40 new members were admitted to the Society, including eight from Germany; Sir H. Rolleston (Cambridge), Prof. Dietrich (Berlin), Prof. Zörkendörfer (Marienbad), and Prof. Devoto (Milan) were proposed as honorary members; and the Council's Committee on Rheumatism was constituted as follows: Dr. Strasser (Austria), Dr. Schmidt (Czecho-Slovakia), Dr. Jansen (Denmark), Dr. Forestier (France), Dr. Fortescue Fox (England), Dr. van Breemen (Holland), Dr. Kahlmeter (Sweden), Dr. Kornmann (Switzerland), a member from Germany to be subsequently added.

An invitation was accepted to hold the next annual meeting of the Society in Italy in October, 1927, on the occasion of the inauguration of the State Medical Service at Monte Catini.

### *International Discussion on the Ætiology and Treatment of Rheumatism.*

Sir William Willcox, in introducing the discussion, developed his well-known view that all forms of chronic rheumatism, articular and non-articular, were produced primarily by septic infection. He admitted many other possible factors in causation, "but," he said, "the contention that any of these can be considered as a main cause of rheumatism cannot be regarded seriously." Even faulty metabolism and endocrine disorders must be looked upon as results of the toxæmia of infection. Sir William Willcox avowed himself an ardent believer in the hydrological treatment of rheumatism after the infective condition had been dealt with, and especially commended intestinal lavage. Stimulation of the general immunity of the body was helpful. Dr. Mougeot, criticising the infective theory of rheumatism and arthritis (these words have a differing connotation in France), said that among latent infections in the arthritic diseases that of the colon occupied in his opinion the chief place. Hepatic insufficiency was also an important ætiological factor, causing a deficiency in oxidising ferments. Hence, probably the value of sulphur waters in rheumatism, for sulphur powerfully augmented oxidation. A third factor in arthritis, especially in middle life, was endocrine deficiency, and trophic changes suggested a nervous element in many cases.

Dr. van Breemen said that the scientific study of rheumatism during the last 30 years had led to a cul-de-sac, mainly as a result of the dominance of pathological-anatomical conceptions and of the classifications arising therefrom. Four separate factors, in his opinion, made up the causation of rheumatism, operating in different degrees in different cases. He suggested that these four factors should be especially studied at all clinics for rheumatic patients: (1) Focal infection and local reactions; local temperatures to be investigated, and evidence sought by blood investigation, &c., of the connexion between focal infection and rheumatic disease. (2) The arthritic diathesis; a study of metabolism, autonomic nervous system, condition of the blood, fatiguability, &c. (3) Derangements in the circulation of the skin. An exact measurement of skin temperatures is required. (4) Reaction to external physical conditions; the influence of heat and cold, dry and moist, as well as occupation to be more exactly studied. Dr. van Breemen regarded chill from exposure to damp cold as an important factor in many cases and advocated external methods of treatment for all forms of chronic rheumatism.

Dr. Kahlmeter, medical consultant to the Board of Pensions in Sweden, said that four special institutions for chronic rheumatic (articular) cases had been set up by the Board. The investigation of results, three years after treatment, showed 60 per cent. of cases at least so far recovered that they were able to maintain themselves; another 18 per cent. improved sufficiently to make a pension unnecessary, and 23 per cent. pensioned. The results were always better in men than in women. Among the different forms of arthritis the "secondary chronic articular rheumatism" (following rheumatic fever or slightly febrile cases) has shown the best results. The non-febrile "rheumatic arthritis" shows somewhat less good results, although this form never has cardiac complications. (A radical distinction is here evident.) Non-articular rheumatic cases (not included in the Swedish statistics) do very favourably at the institutions, about 84 per cent. being reported in good health after three years. Dr. Kahlmeter strongly advocated the provision of special departments for subchronic arthritis in the chief hospitals. Such cases were too protracted for ordinary hospitals and many of them were not yet ready for the spas or institutions under the Pensions Board where baths and other physical treatment were provided. A similar provision (with special departments) was required for crippled persons in Sweden. The Pensions Board was building a rheumatism department at four of the provincial hospitals but still lacked "the most urgent thing," a central arthritic hospital in Stockholm, in connexion with the university, with facilities for special research and teaching in rheumatism. Dr. J. Alison Glover gave figures and diagrams from the British Ministry of Health, exhibiting the nature and extent of the problem of rheumatism in England, to the importance of which the national conscience was being awakened. If only one-quarter of the cases which annually presented themselves in England and Wales required hydrological treatment, some 14 spas such as Pistany, which had 800 beds for insured persons, would be necessary. He agreed with Dr. van Breemen as to the occupational factor in causation, and showed the incidence of osteo-arthritis among metal workers and the influence of climatic peculiarities in the development of rheumatic disease. Prof. Netousek (University of Bratislava), Drs. Schmidt, Wasserman, Higgins, and Poulton also took part, and Dr. Schober emphasised the powerful causative influence of climate, age, and traumatism in most rheumatic affections.

## THE GERMAN SURGICAL CONGRESS.

(FROM OUR OWN CORRESPONDENT.)

AFTER the inaugural proceedings already reported in THE LANCET (April 24th, p. 882), an address was delivered by Prof. A. EISELSBERG (Vienna) on some problems in the

### *Surgery of the Brain and Spinal Cord.*

Nowadays, he said, the surgeon had to operate upon every part of the brain except the pons and the medulla oblongata. The essential was accurate diagnosis. Radiography might be of value to ascertain the condition of the sella turcica and the pterygoid process, but encephalography had not had the effect which was expected and he preferred a probatory exposure of the brain. The results of operation on cerebral growths were not yet as good as they ought to be, although technique and diagnosis had been greatly advanced by Harvey Cushing. In a series of 161 cases 98 of the operations had been successful, and of the last 31 cases only three had died. Growths of the acoustic nerve, according to recent researches, were not of a malignant character and radical removal was therefore unnecessary; the post-operative administration of X rays was of value in treatment. Lumbar puncture, though dangerous with cerebral tumours, should always be performed in growths of the spine. By injections of lipiodol into the cisterna suboccipitalis morbid conditions and growths of the spine became visible. Of 89 growths of the spine 84 were cured by operation. In inoperable tumours administration of X rays produced improvement.

Prof. F. **KRAUSE** (Berlin) spoke on the operative treatment of epilepsy. He said that in Jacksonian epilepsy it was essential to observe the fits. Sometimes a fit apparently began with convulsions of an extremity, whilst accurate observation showed a spasm of the ocular muscles. In such a case it would be a mistake to operate upon the ascending cerebral convolution. In the case of a child where only a very short rotation of the right eye had preceded the fits, these disappeared after a subcortical cyst had been removed from the motor centre of the eye. In genuine epilepsy operations were as a rule useless; only in cases beginning with typical local symptoms might surgical intervention be considered.

Dr. **GULCKE** (Jena) read a paper on Neuromata, of which he described three forms—the first occurring from the brain, especially the acoustic nerve, the second in the medulla, and the third in the peripheral nerves and especially the sciatic.

### *Operation for Bronchial Asthma and for Mitral Stenosis.*

Prof. H. **KÜMMEL** (Hamburg) reported on the results obtained by cutting through the bronchial nerves in asthma. Operation had been done only in cases where other treatment had failed and where the patients could not get rid of the habit of morphia or adrenalin injection. He stated that he had cured the patient in 50 per cent. of cases. In the last case, to avoid undesirable consequences, he had cut through the rami posteriores bronchiales; the operation was somewhat more difficult but was more satisfactory.

Dr. **PRIBRAM** (Berlin) reported on a case of stenosis of the mitral valve due to articular rheumatism 23 years ago. After resection of the left costal cartilages the sternum was divided and after the pericardium had been opened a die-like instrument was introduced into the heart and pushed to the mitral valve, from which a triangular piece was punched out. The hæmorrhage was only slight; the result was that the low blood pressure at once increased. The patient unfortunately died after five days, high fever having set in. Autopsy showed that endocarditis had relapsed at the aorta, producing stenosis there.

### *Operation for Acute Peritonitis.*

Prof. M. **KIRSCHNER** (Königsberg) has collected the history of 10,000 cases of acute peritonitis from the Königsberg and other surgical clinics. The mortality from operation is very high until the fifth year of age, decreases then to the fiftieth, and rises again thereafter. The percentage mortality further depends on the day on which the operation is performed, being 25 when the patient is operated on within the first 12 hours, 32 within 12 to 24 hours, 45 from 24 to 48 hours, and 66 after that time. It follows that every case ought to be operated on at once. To remove the source of the infection the incision must be made long enough to allow full exposure. For removing the exudate irrigation with saline should be done; when only a small quantity is present mopping is sufficient. No compound should be used for the purpose. If the surgeon is sure that he has removed the source of the infection, a suture of the abdominal wound should be performed; if not, the source of the infection and the pouch of Douglas may be drained. The action of the heart must be accurately observed as it suffers very early from the effects of infectious peritonitis. Indiscriminate injection of digitalis and suprarenin must be avoided; injections of morphia to strengthen the heart give good results. Working on these principles, said Prof. Kirschner, the mortality from acute peritonitis had decreased within 30 years from 87 to 30 per cent.

### *Operations on the Colon.*

Prof. O. **NORDMANN** (Berlin) said that radiography showed that there was not only a peristaltic but also an antiperistaltic movement in the colon. Congenital atresia and stenosis were not due to fœtal peritonitis, but to an arrest of development. In these cases, he said, the only suitable operation was the making of an artificial anus above the constriction. Torsion of the cæcum must be operated upon early. In a healthy cæcum retorsion was sufficient; when gangrene had occurred resection of the cæcum together with the ascending colon was necessary. Megacolon was also a congenital condition and was sometimes associated with an enlargement of the urinary bladder. It generally caused symptoms only when kinking had occurred. If irrigation proved useless cæcostomy was preferable to the formation of an artificial anus. In weak patients and in young people operation should be done in two stages. Radiography had proved that diverticulitis was more frequent than had hitherto been believed. In uncomplicated cases resection in one stage was possible, but in complicated the formation of an artificial anus was indicated. Innocent growths such as lipoma and polypus produced symptoms only when they had caused invagination. Cancer of the colon might exist without the blood appearing in the fæces. In cancer of the ascending colon the whole ascending colon with the hepatic flexure must be removed, and an anastomosis made between the ileum and the transverse colon. In cancer of the flexure resection, as extensive as possible, must be performed, and in people with cardiac weakness this had to be done in two stages.

Prof. **SCHLIEBEN** (Frankfort) drew attention to the fact that sometimes polypi of the intestine enclose typical precancerous cells. He therefore insisted upon an accurate microscopical examination of every polypus. The pedicle of a polypus might be formed by innocent tissue, but in another part of the growth cancerous and transitional cells might be present.

### *Transplantation of Cancer.*

Dr. **KURTZAHN** (Königsberg) reported that he had transplanted into himself cancerous tissue removed from the breast. The results were quite different from those obtained in experiments on animals. At examinations made after six days, two weeks, and six weeks only signs of absorption were discovered.

Amongst other papers read before the Congress were those by Prof. L. **REHN** (Düsseldorf) on Constitution from a Surgical Point of View; Prof. **BAYER** (Leipzic) on Transplantation of Joints; Prof. **KOCH** (Bochum) on the Results of Primary Sutures of Complicated Fractures; Dr. **LAHR** (Kiel) on Ischæmic Contractures; and by Prof. E. **JOSEPH** (Berlin) on the Removal of Calculi from the Ureters.

---

**HOSPITALS AND ACCIDENTS.**—The Royal Victoria and West Hants Hospital at Bournemouth has made a rule that any person admitted as the result of an accident who is covered by any form of insurance shall pay 10s. per day for maintenance during his stay in the hospital.

**NATIONAL HEALTH INSURANCE: CERTIFICATES BY NON-PANEL PRACTITIONERS.**—A medical practitioner, who was not a panel practitioner under the National Health Insurance Acts, was asked by a panel patient, who was his private patient, to give a certificate to enable him to obtain medical and sickness benefits from his approved society. The doctor furnished the appropriate certificate and was later informed by his patient that the secretary of the local branch of his approved society had refused to accept this certificate on the grounds that it had not been given by a panel practitioner. The doctor brought this matter to the attention of the London and Counties Medical Protection Society, whose secretary informed him that no approved society was entitled to refuse a proper certificate even though given by a non-panel medical practitioner. The facts were reported to the Minister of Health, who endorsed the advice given by the Protection Society and caused a communication to be made direct to the head office of the approved society concerned.

## PARIS.

(From our own Correspondent.)

### *Further Light on the Tubercle Bacillus.*

Since its discovery Koch's bacillus has been generally regarded as an acid- and alcohol-fast organism growing only at relatively high temperatures and in rich and nitrogenous media, and it has been assumed that the demands it makes on its environment necessitate a parasitic habit of life. Dr. Albert Vaudremer, however, has recently shown that the characteristics of the tubercle bacillus which are usually thought of as absolute are really only relative. It appears from his investigation that the bacillus passes through various stages in development from its original granular state into its ultimate acid-fast form. At different times in its life-history it is able to thrive in different kinds of environment and at temperatures ranging from 15° to 39° C. It develops in media containing only traces of nitrogen and of salts, and at this stage it is not acid-resisting, and does not produce tuberculin; for the production of tuberculin is only possible in a medium rich in nitrogen, and resistance to acid is only developed in cultures containing large amounts of carbohydrates and in the presence of plenty of oxygen. Such conditions are realised in parasitic life, and it was this that led Koch to describe the tubercle bacillus as necessarily parasitic. But in reality it is only the acid-resisting form—the infectious germ—which is necessarily parasitic, and this germ, which is composed of granular elements, has particles which can pass through a porcelain filter and on subcutaneous injection into guinea-pigs can produce lesions comparable to those of surgical tuberculosis in man; on intravenous injection of filtrate a rapidly fatal septicæmia is induced. His observations led Dr. Vaudremer to attempt vaccination of guinea-pigs by subcutaneous injection of tubercle bacilli grown on potato broth without glycerine and killed by heat at 59° C. For 15 months after such vaccination the guinea-pigs resisted infection and reinfection with doses of tubercle bacilli which, according to experience, should have proved fatal within 60 days.

### *Denervation of the Ovary.*

Investigations made by Dr. Jean Lhermitte and Dr. Robert Dupont (both of Paris) of 16 cases have shown that the nerves to the ovary are specially abundant in the central region of the hilum, that they do not follow the vessels, and that on entering the ovary they lose their sheath of Schwann. Histological and anatomical research led them to attempt the relief of the painful symptoms of sclerocystic oöphoritis by denervation of the ovary. This operation has been done nine times, and, although the experiment is only recent, it is not too much to say that the results are encouraging and justify further trial.

### *Botelho's Sero-reaction for Cancer.*

Prof. Hartmann lately gave a demonstration before the Académie de Médecine of the sero-reaction devised by his pupil Botelho, who has been doing research on cancer at the Hôtel-Dieu for several years. The reaction, which seems to depend on a precipitation of albuminoid substances in determined conditions, is shown to be positive in 90 per cent. of cancerous patients and in only 14 per cent. of the non-cancerous; the fact that the serum of pregnant women often gives a positive reaction is noteworthy. On complete extirpation of a new growth or after effective treatment with radium or X rays, the reaction again becomes negative, which is interesting as showing that it does not depend on a diathesis, but rather on the formation by the tumour of substances which circulate in the blood. This hypothesis has been confirmed by Itchikawa who produced experimental cancer by painting the rabbit's ear with tar, and found that Botelho's reaction became positive in the rabbit's blood as soon as the cancer became definite.

### *Surgery and Latent Tuberculosis.*

Bezançon and Jacquelin[1] consider that among the causes which reactivate tuberculous infections dating from childhood, and give rise to pulmonary tuberculosis, surgical intervention plays a definite part. Here they are not referring to tuberculous metastases following operations on tuberculous lesions, but rather to the development of pulmonary tuberculosis following operation on organs free from all tuberculous infection. From their study of seven such cases in the last two years, they have come to the conclusion that the anæsthetics which have the most decidedly reactivating influence on the tuberculous lesion are also those which are most damaging to the liver cells; and they say that the systematic study of the cutaneous reaction to tuberculin establishes the existence of a fairly definite state of post-operative anergy. The moral of their research is that patients suspected of tuberculosis should not be operated on if it can be avoided, and, if operation is imperative, the least toxic anæsthetic should be used. In this respect local or spinal anæsthesia or even nitrous oxide gas are very much less harmful than chloroform or ether.

### *Bread and Flour.*

The President of the Republic has signed a decree requiring the addition of 8 per cent. rye flour to the wheat flour used for making bread in France. The rye may be replaced by rice or barley in regions where rye is scarce. French household bread will thus resemble very closely the same class of bread used in Switzerland before 1914, when the supply of rye from Central Europe was cut off.

### *Injections of Oxygen for Hydrarthrosis.*

De Mello, of Lisbon, reports that local injections of oxygen act more surely and rapidly than massage in curing hydrarthrosis of the knee due to trauma. Twenty-seven cases have been treated and not more than three injections were required in any of them. At each injection about 300 c.cm. of oxygen is introduced between two rubber bands placed above and below the knee in such a way that the gas accumulates between them.

Bonnet reports that butelline (sulphate of para-amino-benzoate of di-n-butyl-amino-propanol) is excellent for anæsthetising the mucosa of the uro-genital tract. Solutions may be of 1, 2, or 4 per cent. The substance replaces cocaine, for it is very stable, may readily be sterilised, and does not seem to produce toxic effects.

Following the recent death of an intern at the Bicêtre Asylum from scarlet fever, French physicians are considering the provision of better protection and compensation for hospital doctors. So far free treatment in hospital has been the only benefit accorded to those who suffer in the course of their duty, and medical men are not included in the compensation and indemnity regulations of 1898.

The figures for the Census taken in Paris on March 7th are now available. The population on that date was found to be 2,838,416, which is about 25,000 less than it was five years ago.

The seventh international meeting organised by the Paris Society of Neurology will be held at the Salpêtrière on June 1st and 2nd. The principal subject of discussion will be the present clinical methods of examining the sympathetic. Information may be had from Mr. O. Crouzon, 120, Boulevard St. Germain.

Two courses in oto-rhino-laryngology will be given this summer. From June 21st to July 3rd a course will be held at Bordeaux, information about which may be had from the Secretary of the Faculty of Medicine. The other is from July 5th to July 13th at Toulouse; details are supplied by the Secretary of the Faculty of Medicine there.

---

[1] Vide Paris Médical, March 27th.

A post-graduate course in dermatology will be held at the University of Strasbourg from Sept. 20th to Nov. 6th. Applicants should write to Prof. Pautrier, 2, Quai St. Nicolas, Strasbourg.

The death is announced of Dr. Amand-Elzéar Gauthier at the age of 76. He was senator for the Aude and was three times Minister of Public Works.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

### *Local Appointments.*

THE Minister for Local Government and Public Health introduced to the Dail recently a measure designed to make a radical change in the method of appointing the officers of local authorities. It deals not only with the officers of county, county borough, and district councils, but with agricultural, technical instruction, and school attendance committees. The Bill provides that in future such local authorities shall only appoint to offices on their staffs persons already in their service, or in that of other local authorities. In other cases the appointment is to be made by the Minister—of Local Government and Public Health or of Agriculture or of Education, as the case may be—acting on the recommendation of a body of not more than three Local Appointments Commissioners, who are to be appointed by the Executive Council. In making their selection the Commissioners are to act "solely by means of competitive examination," and they are empowered to draft regulations to govern such examinations. This mode of selection, however, will not apply in cases in which the Commissioners consider that candidates could not be satisfactorily selected by competitive examination in view of the knowledge, experience, or qualifications required for the post. In such case the Commissioners may make their selection in any way they think fit. A marginal note suggests that this exception is meant to apply to offices whose duties are of a professional or technical nature. As the Bill covers all appointments of medical officers under local authorities, it is of great interest to medical men. In removing the patronage of such officers from local authorities it tends to remove one of the great obstacles to the establishment of a State Medical Service. It would be satisfactory, however, to see more precise conditions laid as to the procedure to be employed by the Commissioners in dealing with professional appointments.

### *The Coroners Bill.*

It is understood that the Coroners Bill at present before the Senate has undergone important changes in Committee. The principal additions are as follows: A coroner's jury shall be composed of not fewer than six or more than 12 persons. The fee of a special expert witness is fixed at £10 10*s*., plus certain expenses of attendance. The present fee payable to a practitioner for giving evidence at an inquest when no post-mortem examination has been made is £1 1*s*. In the new Bill the Select Committee has altered the sum to "not exceeding £2 2*s*." The fee for making a post-mortem examination, and reporting to the coroner without giving evidence is altered in the Bill from £1 11*s*. 6*d*. to "not exceeding £3 3*s*.," and the fee for a post-mortem, report, and evidence is increased from £2 2*s*. to "not exceeding £4 4*s*."

### *The Dublin Hospitals and the Rockefeller Foundation.*

There have been for months past a number of rumours current in Dublin regarding applications said to have been made to the Rockefeller Foundation for funds to build an amalgamated hospital. Last week Sir William Taylor, in a speech at Sir Patrick Dun's Hospital and in a letter to the daily press, stated the facts. The boards of governors and the medical staffs of five hospitals—Dun's, Mercer's, Meath, Adelaide, and Royal City of Dublin—are agreed upon the principles of amalgamation if the necessary money for the accomplishment of the project should be forthcoming. Sir William Taylor, as chairman of the committees of the amalgamation scheme, asked the representative of the Rockefeller Trust, who visited Dublin last year, for the sum of £1,250,000, a sum equal to that given to University College Hospital some three years ago, and requested that of that sum about 40 per cent. might be expended on building and equipment—conditions similar to those under which the University College grant was given. No answer has yet been received, and a representative of the Rockefeller Foundation is to visit Dublin in the autumn of this year. A statement has been made that the Rockefeller Foundation has delayed considering the application in view of the uncertainty of the relation of Ireland to the Medical Register, but no such reply has reached Sir William Taylor.

### *Professorships at the School of the Royal College of Surgeons in Ireland.*

The President, Vice-President, and Council of the Royal College of Surgeons in Ireland have made appointments to three of the vacant chairs in the School of the College. Dr. George E. Nesbitt has been appointed professor of medicine; Dr. Andrew H. Davidson, professor of midwifery and pharmacology; and Dr. Leonard Abrahamson, professor of pharmacology. The appointment to the chair of physiology will be made next month.

## NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

### *Births and Deaths in Madras.*

IT is at present impossible to compile really accurate vital statistics in India owing to the difficulty of securing the registration of births and deaths. In the Madras Presidency no less than 63,785 unregistered births were brought to light by the district health staff during 1924, and it is certain that even this number does not represent anything like the total. The number of births registered in that year was over 1,400,000, which was an increase of 72,000 over the figure for 1923, and represented a birth-rate of 34·9 per 1000 instead of 28·8 for the previous five years. The increase is evidence of the vigilance of the district health staff. Deaths numbered slightly more than 1,000,000, which was also a slight increase; the death-rate in municipalities increased from 20·7 in 1923 to 32·2 in 1924. About 52,000 deaths from cholera were registered, as compared with 5000 in the previous year, and the figures for diarrhœa and dysentery rose in similar fashion. The diseases were widespread, but most of the festivals passed off without untoward incident, so that the trouble and expense involved in their sanitary management seem to have been justified. The Director of Public Health is able to report that the people themselves rendered considerable service to the health staffs and a large number of prophylactic injections against cholera were given. Small-pox mortality declined by over 6000, the total number of deaths in 1924 being not quite 10,000. Plague gave little trouble, but under the heading Fevers no less than 322,000 deaths are reported, and a large proportion of these is doubtless due to malaria and, in municipal towns especially, to typhoid.

Madras Presidency has a provincialised cadre of district and municipal health officers and there is no longer a lack of candidates for appointments. It is clear that local bodies have begun to realise the advantages of having such officers, and, as the Government pays 75 per cent. of their salary, very little additional expenditure is incurred for them in the municipal budgets.

### *The Medical Profession in India.*

An interesting, if sombre, account of the present position of the medical profession and medical research in India was given to the Indian Science

Congress in the presidential address[1] of Colonel Raghavendra Row. The profession, he said, consisted of a heterogeneous mass of members who were, unfortunately, marked off into watertight compartments, as was perhaps natural in a country where the caste system permeated every institution. First there was the small number of men belonging to the superior services, who were chiefly members of the Indian Medical Service transferred to the civil side; next there was a large body formed of two distinct classes of the subordinate service—the assistant surgeon class, drawn from university graduates, and the sub-assistant surgeon class trained in the medical schools; lastly, there was a very large body of private practitioners. There was an official side and a non-official side, with various grades, "and each with its own vested interests." And all these were called upon to serve a vast mass of uneducated and unappreciative humanity, without the basis of one common interest and ideal such as guided the profession and the public in England. In spite of the strenuous and most earnest efforts of the senior members of both official and non-official sections, said Colonel Row, there was a conflict of classes and individuals which inevitably prevented cohesion and the formation of a corporate profession. Unfortunately, even those private practitioners who were inclined to undertake post-graduate work generally confined themselves to clinical study, forgetting the importance of research. Those who went abroad seemed to be drawn chiefly towards the acquisition of high-sounding degrees which ensured a lucrative practice on their return to India. The scientific atmosphere did not exist. The attitude of the public towards the profession was lamentable; it was difficult to awaken the public conscience of the wealthy classes to their duty towards the less fortunate poor, and to interest the general mass of the public in the finer shades and different functions of the various branches of the profession and their comparative importance in the growth of medical science was out of the question. Outside the five or six Government laboratories, staffed mainly by the I.M.S., which were doing admirable work, research was practically dead and the outlook for the future unpromising. "The standard of teaching and training in Western medicine," Colonel Row said, "is rapidly falling. The students are too illiterate to understand what they are taught; the teachers too inexperienced in teaching to be able to train men in the early stages of their professional teaching. . . . . Examinations are no longer run on honest lines." He deplored the threatened decadence or disappearance of the I.M.S. which, he said, had founded the medical colleges and directed medical education, having always given of its best. What must be done was to build up a substitute service not only of equal accomplishments, versatility, and distinction, but based on a much broader and cosmopolitan policy of selection purely with a view to efficiency. For this purpose material, money, and men were needed. India was unrivalled as a field for the medical investigator; money ought to be obtainable and support had already been received from the trustees of the Rockefeller Foundation. The supply of men was the main difficulty. Expert advice must be imported at whatever cost. No matter what political goal was in view for India, there must be not only a well-organised profession, but also the machinery to ensure the continuous production of men capable of undertaking by themselves the solution of the scientific problems of the country.

### *Propaganda and Health.*

In a report on India in 1924–25 Mr. Rushbrook Williams, Director of Public Information, speaks of the need of an organised public opinion to overcome the deadweight of age-old inertia. Organisations such as the Servants of India Society and the Social Service League are doing admirable work, and if only India could be covered with a network of similar organisations the sanitary problem, he says, would be solved in no long period. During the last ten years much has been done to improve the sanitation of the larger towns, but progress is always very slow, as deep resentment is excited by interference with customs of long standing. In consequence, sanitary regulations are all too commonly proposed with timidity and reinforced without zeal. So far as rural sanitation is concerned the position is even less satisfactory and an immense effort is needed. Public health departments all over India are now organising propaganda work in rural areas and the coöperative movement is displaying its potentialities in this, as in other fields.

One of the most urgent problems is the supply of even elementary medical assistance to the remoter parts of the countryside. The Government of Bombay has sanctioned a village aid scheme for the training of selected primary school teachers in the rendering of simple medical aid. The Madras Government has announced a scheme for subsidising private practitioners to take up work in newly established surgical centres where medical aid is at present not available. By this and similar means it is hoped gradually to bring advanced medical aid within the reach of every locality.

Another instance of the successful use of propaganda is afforded by the movement known as the National Baby Week, which was initiated by Lady Reading and has caught the imagination of large sections of the people all over India. Infant mortality is among the most pressing problems of Indian public health. Probably every year some 2,000,000 Indian babies die within the first year of life, the death-rate varying from 200 to 600 per 1000 births. It would be difficult to exaggerate the practical importance of the infant welfare movement. The baby shows, which are held annually in all the most important centres of India, have aroused public interest to an unprecedented degree. Year by year the number of towns and villages applying for assistance in organising a baby week increases, and there is an ever-growing demand for leaflets, pamphlets, model lectures, cinematograph films, and magic lantern slides. Various voluntary associations and institutions have thrown themselves with enthusiasm into the task of furthering this campaign, but the scope for child welfare work is so extensive that many years must elapse before the problem can be pronounced as on a fair way to solution.

It is noteworthy that during 1924 nearly 34,000 lectures on health matters were delivered in over 27,000 centres in the Madras Presidency. About 1,500,000 people were thus addressed, and as many as 51 exhibitions were arranged at fairs and festivals.

### *Adulteration of Ghee.*

During a discussion in the Council of State the adulteration of ghee (clarified butter) with vegetable oils was admitted to be widely prevalent. It was stated that the large increase in the import of vegetable oil was due to the demand for ghee far outrunning the supply; vegetable oils were needed to make up the deficiency. Fat taken out of animal carcasses is also used to adulterate ghee. The Government speakers considered the imported vegetable oil to be wholesome, but it is devoid of the vitamins in which clarified butter is rich.

The Bengal Council has passed a resolution making physical culture compulsory for students between 12 and 18 years of age in all schools affiliated to the Calcutta and Dacca Universities.

A Bill to control medical education throughout the Indian Empire has been introduced into the Legislative Assembly. At present there is no Imperial measure but there are individual medical Acts for each province.

The rapid extension of Indian universities is leading to financial difficulties. The University of Lucknow, for example, has shown a deficit in its budget for the past five years owing to the insolvency of some of those who promise subscriptions.

## MENTAL HOSPITAL REPORTS.

THE *City of London Mental Hospital* at Stone, Dartford, had 783 patients under treatment during 1925, and of these 65 were discharged recovered or relieved. The death-rate for the year was 6·4 per cent. Nineteen voluntary boarders entered the hospital during the year and eight remained in residence at the time of the report. Parole was granted to 94 cases and leave of absence on trial to 78. Parole patients can make full use of the library which has been equipped for the use of patients and staff. The new operating theatre, X ray room, pathological laboratory, and isolation block for noisy patients are all nearing completion, and should prove important and valuable additions to the accommodation of the hospital. Eleven male and five female nurses hold their mental certificate, and the appointment of a sister tutor is under consideration.

The report of the *Inspector-General of the Insane for Victoria, Australia*, for 1924 has recently appeared in print. There are over 6000 certified persons in the State, a ratio of 1 : 268 of the population. The female cases are on the increase, but the male figures are decreasing. The mean age of admission to the State hospitals was 43·5 years, and over one-sixth of the cases were more than 60 years of age. There were 41 cases of general paralysis—half the number admitted 15 years ago—and the Inspector considers that there is a marked diminution of active syphilis in the community. There was a general discharge rate of 50 per cent. and death-rate of 7·97 per cent. Post-mortem examinations were performed on three-quarters of the fatal cases. There are nine institutions; the patients from Yarra Bend have been evacuated to Mont Park, save for some 50 male patients who keep the farm and garden going. Kew is uncomfortably overcrowded with over 1000 patients, and the report echoes a plaint common in the reports of this country—viz., that mental institutions ought not to be filled up with senile patients. There is also at Kew a colony for mental defectives where nearly 400 patients are accommodated. Ararat and Beechworth are smaller hospitals with about 600 cases. At the latter, as at Kew and Yarra Bend, there were cases of typhoid, and colitis is always present owing to the absence of proper sewering. At Sunbury there are 1000 patients, and the superintendent believes in giving the utmost possible amount of liberty to all cases who are not completely demented. At Ballarat there are between 600 and 800 patients. Royal Park has a receiving house through which over 700 cases passed during the year; 400 had to be certified, while some cases of confusional insanity and recent mania and melancholia recovered. The superintendent states that "effective treatment and classification are impossible under the conditions of overcrowding which has become chronic." 400 cases were under care at the mental hospital, including a number of voluntary boarders. The voluntary clause appears to be abused here, as in America, and used chiefly by inebriates who make no real attempt to regain self-control. At Mont Park, after the transfers from Yarra Bend, there were 800 cases. The military patients have been removed from Mont Park, leaving that hospital almost unique in having adequate accommodation on its male side. A home for the tractable, bedridden, and sick military mental patients has been opened at Bundoora. A whole-time visiting dentist has been appointed and visits Royal Park, Kew, Sunbury, and Mont Park. He treated nearly 800 patients during his first year and hopes, when he has overtaken the accumulation of work awaiting him, to undertake research into the association of mental and dental defects. The impression given by the report is that the mental hospitals of Victoria are not in a satisfactory condition. Every superintendent speaks of unmade roads, insufficient accommodation, inability to obtain nurses, and the need of works and renovations which have long been recommended but never supplied. Three institutions are without water-borne sewage and two without recreation hall for dances, entertainments, or religious services. There is one pathological laboratory—at Royal Park—but the time of the pathologist is largely taken up with post-mortem examinations of which he performed 223 during the year, many of them on senile patients. In no other country or State is it necessary to have post-mortem examinations by a special officer on every patient reported to the coroner, and this practice deprives the pathologist of opportunities for research. He has, however, published papers on Mongolian idiocy and epiloia. The State of Victoria appears to be carrying economy too far.

The *Boston Psychopathic Hospital, U.S.A.*, is in the forefront of up-to-date and enlightened psychiatric work. Ten reports from different departments are included in the pamphlet. The director makes his subject vivid by giving brief paragraph reports of illustrative cases. Less than 100 patients were actually in the institution at the close of the year, but another 60 were still on the books and nearly 2000 had been given advice or treatment in clinics during the 12 months. Pathological investigations centred largely around the problems of endocrinology and basal metabolism. Of particular interest are the schizophrenic group, which show low basal metabolism without other evidences of hypothyroidism. Other lines of research include blood-sugar, the Kottmann reaction, the cardio-ocular reflex, the protein and sugar content of the cerebro-spinal fluid, and the puerperal psychoses. The resident dentist saw 1025 patients, and 131 cases were examined by X rays. The out-patient department sees every variety of psychopathic difficulty, the majority of the cases being referred by physicians, courts, social agencies or other hospitals; 15 per cent. were diagnosed as psychotic and another 15 per cent. as feeble-minded. The psychometric examination system continues to work well. The distinctive tests of the Kuhlmann scale have been organised into a test series and one worker has standardised a simple test of manual dexterity. The neuropathologist performs autopsies in various hospitals which have no pathologist, and has recorded three cases of pellagra and a series of statistics of the weight of the heart in cases of dementia præcox compared with its weight in other psychoses. A careful histopathological and histochemical record was made of a case of Westphal-Strümpell pseudosclerosis following erysipelas. The Department of Therapeutic Research has concluded that tryparsamide is a valuable addition to antisyphilitic drugs and has used and compared several methods of treatment for neurosyphilis, and has started investigations on some new tests for the cerebro-spinal fluid. The social service department and occupational therapy department are integral parts of the working of the institution. Every effort is made to suit the occupation to the ability of the patient and to get work out of him that he may feel proud of, whether it be winding yarn, bookbinding, or linoleum colour printing. A number of patients were referred from the out-patient department and were helped to bridge the difficult period of readjustment. In some cases the knowledge of craft work gained while in hospital paved the way for economic rehabilitation on discharge. The hospital claims with justice to be one of the world's finest centres of education in psychiatry for doctors, nurses, and social workers, and there is a constant stream of learners or junior helpers passing through its various departments. The director and his many assistants are to be congratulated on their ambitious and successful team-work.

The main note of the beautifully produced, illustrated, and indexed annual report of the *Besford Court (Pershore) Catholic Mental Welfare Hospital for Children* is one of relief that a strenuous year of tension and anxiety has been ended and that the changes foreshadowed in the last report have been successfully put into effect. Besford Court limits its

Dr. Robert [illegible]

activities to preparing for social life those higher grade feeble-minded children who are capable of living in the world and earning their keep, under occasional supervision through an after-care association. The superintendent discusses the various kinds of mental defects, the possible ways of dealing with them, and the inadequacy of existing institutions. He points out that although Besford Court has had to assume the name of "special residential school" in order to fall within official categories, yet it is intended for quite different children and works along different lines. He regards the large mixed institution as the best type for dealing with permanent institutional cases, but the worst for those children who are destined to return to society. Clockwork routine and the institutional spirit are fatal to a mental welfare hospital, and every effort is made to keep the "family" spirit supreme at Besford Court. An after-care scheme provides that old boys who find themselves in difficulties shall have somewhere to turn until smooth water is again reached. The report discusses the psychology of mental defect and the failure of routine education and "bogus" classes. Every trade taught at Besford is one at which the boy will be able to earn his living, and the managers decided on building as the best trade to make a start with. After six months' grounding in their subjects the boys were able to erect a bungalow. "Culture" classes—for want of a better name—alternate with the "vocational" classes, and the boys are encouraged by all the most modern methods to read and learn the general school subjects. The Montessori system is employed by the nuns who run the junior department. The usual summer camp was held at Lulworth, and 15 of the elder boys made the pilgrimage to Rome. A quasi-naval uniform and discipline was decided on, the livery of the senior Service being chosen because of its tradition of responsibility and initiative, and its association with transport and other constructive services to civilisation.

## SCHOOL MEDICAL SERVICE.

THE following table summarises the figures given in the school reports of Glasgow and Aberdeen:—

| Name of city. | No. on roll. | Av. elem. school attendance. | No. of routine children examined. | No. of special examinations and re-inspections. | Percentage of children found on routine examination requiring treatment.* |
|---|---|---|---|---|---|
| Glasgow .. | 183,853 | 87·9 | 48,275 | 37,032 | 48·6 |
| Aberdeen .. | Not given. | Not given. | 8,207† | 10,608 | 18·8 |

* Excluding uncleanliness and dental defects.

† This includes the cursory examination of 3066 entrants.

### *Glasgow.*

It is unusual nowadays to find the annual report of the S.M.O. for a large city given as an appendix to the report of the Director of Education. This arrangement leads to much of the medical work being described by a layman, with consequent loss of interest to medical men; whilst the S.M.O.'s report largely resolves itself into a statistical compilation from which little can be gathered of the actual working difficulties or of the schemes evolved to meet local conditions. Dr. E. T. Roberts shows that rickets is still the greatest single cause of crippling in Glasgow. Rickety deformity accounted for 21·8 per cent. of the recommendations for admission of children to schools for the physically defective, and marked rickets was found in 2·9 per cent. of the children in routine examinations. High as this figure still is, there has been a rapid and steady decrease from 4·1 per cent. in 1923 to 2·9 per cent. in the past year in spite of great industrial depression. Sixty-seven per cent. of the parents attended the medical inspections, and this close contact with the school doctors is rapidly bringing to the public generally the practical lessons of scientific knowledge. At the routine examinations in Glasgow the inspecting officer not only diagnoses but prescribes treatment and thus enables the ailing child to be at once dealt with at the minor ailment clinics. The numbers attending the clinics show a steady increase because parents are coming to realise the advantages of early treatment. Wide provision is made for the treatment of delicate children, and special classes, schools, and institutions are available for all classes of exceptional children. Interference with breathing, recurrent sore-throat, deafness, and otorrhœa were the indications tabulated before removal of tonsils and adenoids in 213 children. On examination, not less than six months after operation, it was found that 184 were cured, 28 were improved, and one showed no change. Two interesting tables are given, one showing that the physique of children examined varied almost strictly according to the number of rooms per family, and the other that the average number of rooms per family was lower in the present area in 1924 than it was in the smaller area of the Glasgow School Board in 1912.

### *Aberdeen.*

Dr. G. Rose gives facts and figures indicating that, though statements about the condition of the teeth of the community are disheartening, there are, nevertheless, gleams of hope. During the past ten years there has been gradual improvement in his area and enlargement of the dental staff is badly needed. The number of physically defective children in special schools is only nine, for many children who would in other districts be sent to such schools are retained in the ordinary schools—including apparently those with amputations and arrested tuberculous disease of the bones and joints, provided this is not made impossible by crutches or orthopædic apparatus. Dr. Rose notes the establishment of sounder views about the mentally defective. At first it was believed possible by intensive teaching to bring them to the level of their fellows, but it is now agreed that they cannot be educated along with the normal. On the other hand, it is recognised as an economic error to suppose that they do not need care, training, and special treatment, including special methods in dealing with delinquents. Dr. Rose insists on the curability of nocturnal enuresis and special treatment is given at the clinic. He maintains that cases of minor defective vision and hearing should be discovered by the teachers and placed in the front row of their class in spite of any administrative difficulties. We heartily commend this procedure even for areas where schools for the partially blind and for the hard of hearing exist. Slight defects of the sense organs, if unrecognised, may be a real handicap to education.

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 8TH, 1926.

*Notifications.*—The following cases of infectious disease were notified during the week: Small-pox, 174 (last week 140); scarlet fever, 1426; diphtheria, 968; enteric fever, 37; pneumonia, 1034; puerperal fever, 51; cerebro-spinal fever, 9; acute poliomyelitis, 1; acute polio-encephalitis, 1; *encephalitis lethargica*, 41; dysentery, 2; ophthalmia neonatorum, 85. There was no case of cholera, plague, or typhus fever notified during the week.

In London itself there was notified no case of small-pox scarlet fever, 236; diphtheria, 273; enteric fever, 7; pneumonia, 96; puerperal fever, 8; cerebro-spinal fever, 1; encephalitis lethargica, 5; and ophthalmia neonatorum, 8.

*Deaths.*—In the aggregate of great towns, including London, there were 5 (3) deaths from enteric fever, 68 (23) from measles, 13 (2) from scarlet fever, 36 (2) from whooping-cough, 43 (12) from diphtheria, 51 (12) from diarrhœa and enteritis under 2 years, and 149 (23) from influenza. The figures in parentheses are those for *London itself.*

(The Registrar-General's weekly return has not yet been printed, and we are indebted to the Ministry of Health for these figures.)

## CHOLECYSTOGASTROSTOMY FOR INACCESSIBLE GASTRIC ULCER.

*To the Editor of* THE LANCET.

SIR,—No conservative surgeon, I think, can have failed to be impressed with Mr. L. R. Braithwaite's article in your issue of May 1st, wherein he suggests that the best surgical treatment for inaccessible gastric ulcers may lie in anastomosis between the gall-bladder and the stomach.

I have been much exercised in mind as to what should be done in such cases, and am entirely in agreement with his view that gastro-enterostomy by itself is of little avail. This may be due to the fact that in cases of this kind it is often anatomically impossible to place the opening in the stomach on the cardiac side of the ulcer. Jejunostomy alone, without gastro-enterostomy, does afford rest to the stomach and a means of subsistence to the patient. I have recently referred in detail to cases treated in this way in my Hunterian lecture on the Surgery of the Jejunum. Clinical cure is not difficult to obtain. Mr. Braithwaite says that all his cases have relapsed. That is not my experience, and several of my patients have returned to arduous occupations without recurrence of symptoms. Nevertheless, I do not regard them as completely cured because X ray examination still shows either a bubble of air or a fleck of barium in the site of the old crater. But in any case this method of treatment cannot be popular, and is only put up with by those who have been martyrs to gastric pain. All my patients have yielded to temptation by the time six months has elapsed from the operation. Large resections for small ulcers do appear to be mutilation and large resections for large ulcers are often dangerous. If, therefore, nature offers the gall-bladder as a dock-leaf for the sting of an ulcer, gastric surgery may be simplified and rendered safer.

There appears to me, however, a slight inconsistency in Mr. Braithwaite's argument. He admits the hyperacidity of the gastric contents in duodenal ulcer, but states that no characteristic rise is found in gastric cases. Yet he claims that cholecystogastrostomy—his operation of choice for inaccessible gastric ulcers—reduces the gastric acidity. Does this mean that it requires something more than 0·2 per cent. of total HCl to produce a duodenal ulcer, but that a gastric ulcer patient is one whose mucosa won't stand even 0·2 per cent.? Of course, we do not know for certain whether hyperacidity is cause or effect as regards ulcer, though my experience of jejunal ulcers is that it is most likely to occur in patients whose gastric acidity remains abnormally high even after gastro-enterostomy. If such ulceration always starts, as Walton holds, at the anastomotic line, then technique is probably more concerned than hyperacidity, and the ulcer dates from the time of operation, mucosal healing never having been achieved.

It would be interesting to know whether bile enters the fasting stomach of the patient who is fed solely through a jejunal tube. So far I have made no observation on this point, but my impression is that reflux through the pylorus does still take place. This may be a factor in promoting healing together with the rest which the stomach enjoys. Mr. Braithwaite hints that it is possible to have clinical without chemical hyperacidity, but I think he should speak rather of hyperactivity. Alkalies may delay mobility as well as reduce acidity. The same may apply to bile in the stomach. The point which I am not clear about is the distinction he makes between gastric and duodenal ulcer and their treatment by "bilification." He suggests cholecystogastrostomy in stomach ulcer and cholecystoduodenostomy in duodenal ulcer, and yet Mr. Braithwaite considers that the operation attempts only a reduction of gastric acidity. Surely in the case of duodenal ulcer the anastomosis should still be with the stomach, and perhaps the ideal operation would be to short-circuit the pylorus and first part of the duodenum with a gastroduodenostomy, and also anastomose the gall-bladder to the stomach proximal to this. Such a procedure would probably be of wider application than an anastomosis with the gall-bladder placed between the pylorus and an ulcer which is rarely more than an inch distant from it.

In the case of gastric ulcer Mr. Braithwaite has suggested that a jejunostomy might also be advisable to secure rest for the stomach. Possibly with the addition of a cholecystogastrostomy to "bilify" the ulcer and to protect the jejunum the value of gastro-jejunostomy may be re-established. This would add greatly to the comfort of the patients concerned. In my experience of opaque meals after gastro-enterostomy it is rare to find that more food passes through the pylorus than the anastomosis, even years after the operation.—I am, Sir, yours faithfully,

Harley-street, W., May 5th, 1926. JOSEPH E. ADAMS.

---

## CHRONIC DUODENAL AND GASTRIC ULCER.

*To the Editor of* THE LANCET.

SIR,—I have read with interest Mr. Braithwaite's paper in your issue of May 1st on the Surgical Treatment of Chronic Duodenal and Gastric Ulcer. He voices certain opinions which, as a student of gastric problems, I should be inclined to dispute, and notably among which I would include (1) his suggestion that any dyspepsia which has resisted medical treatment for two years and is not due to such general causes as phthisis is due to organic disease of the stomach or duodenum; (2) his observation that gall-stones never produce a painful dyspepsia; (3) his reference to hyperchlorhydria as if it were a disease in itself instead of a symptom; and (4) his apparent support of the view that gastric acidity is the more important factor in perpetuating ulcers. On none of these points, however, do I wish to join issue here, and all of them I have discussed elsewhere.

The sentence in his paper which particularly attracted my attention was the following:—

> "There are many surgeons who will not operate without a Rehfuss test—i.e., an estimation from hour to hour or less of the free acid in the stomach. The process of swallowing and keeping the necessary tube is much resented by most patients, and in my view, except as research on gastric secretion, is of small value."

I can only suppose that Mr. Braithwaite has had a very small personal experience of the fractional test-meal. Since 1910 I have had occasion to employ the fractional method as one among other routine methods of assessing gastric efficiency in many hundreds of hospital and private patients; it is employed as a routine both by physicians and surgeons at Guy's Hospital; Dr. T. Izod Bennett and I examined over 100 healthy medical students with the method, and I have had many test-meals myself for experimental purposes. The test is not very disturbing and, although few people would swallow the tube as a pastime, I have never heard any serious complaint from my patients; those who have had previous experience of the large stomach-tube usually prefer the small one, although it must be retained longer; and, finally, the test is, to say the least, a great deal more comfortable than many other diagnostic intubations such as œsophagoscopy and cystoscopy. The value of fractional analysis in the so-called "surgical dyspepsias," and especially in assessing the suitability of certain cases for certain operations and in studying their late results, to my mind, is very great. In the section of my Goulstonian lectures (1925) dealing with gastro-jejunostomy the following sentence occurs:—

> "In the light of modern experience it seems fair to insist that no gastric surgery other than urgent surgery should be undertaken for the relief of symptoms due to an active ulcer without a preliminary fractional gastric analysis as well as a radiographic examination."

To this opinion I adhere.

I should very much like to know how Mr. Braithwaite can justify his plea for new operations which greatly modify the physiology of the stomach, unless he is prepared to study the physiology of the stomach—otherwise than by the eye of faith—both before and after surgical intervention. If he is not prepared to do this he is exposing himself to the criticism that he has resorted to the old principle of "*trial and error*"—a principle which is hardly worthy of modern surgery. It seems to me unwise, on the experience of a single year and only 19 cases, even to hint that the operation of cholecystogastrostomy for inaccessible gastric ulcer "may become the operation of choice," unless he is taking steps (as I hope he may be doing already) to inquire what derangement of function, if any, is present before the operation; what modification of acidity and emptying rate is achieved by the operation; and what evidence there is that alkalinisation causes healing. Rehfuss's tube and the fractional test-meal would greatly help him in such inquiries.

It has taken a quarter of a century to discover the limitations of gastro-jejunostomy and to explain its sequelæ. Many physicians and surgeons even now are uncertain as to the absolute indications and contra-indications for the operation and the actual modifications of function which it produces. In the last few years I have collected clinical and test-meal observations on a group of cases illustrating six distinct and troublesome complications of gastro-jejunostomy. Should we not therefore be very cautious in our advocacy of new measures such as gastro-duodenostomy, gastrectomy, and cholecystogastrostomy, at any rate until they have borne the test of time?

I do not write as a physician opposed to the surgical treatment of gastric and duodenal ulcer. A large proportion of my ulcer cases are referred, after investigation and selection, to my surgical colleagues, but I do believe that we owe it both to our patients and our art to analyse as carefully as possible the reasons for our very responsible actions and the reasons why certain procedures, frequently very successful, are still followed, rather too frequently, by unhappy results. If we wish to introduce and perfect new reconstructive operations for the relief of gastric disease we must study our cases critically by all the established tests at our disposal.

I am, Sir, yours faithfully,
J. A. Ryle.
Wimpole-street, W., May 1st, 1926.

## WHAT IS ORTHOPÆDIC SURGERY?

*To the Editor of* The Lancet.

Sir,—My letter of April 3rd (p. 734) was prompted by a certain concern for the future of surgery. Mr. Elmslie will believe me that it was not dictated by any feeling of hostility to the specialty he so ably practises or to my personal friend and colleague who presides over the Orthopædic Section of the Royal Society of Medicine.

In reply to my question, "What is orthopædic surgery?" Mr. Elmslie gives three alternative definitions of its scope (The Lancet, April 24th, p. 884): (*a*) surgery, excluding certain large branches, notably abdominal surgery and the surgery of malignant disease (including, however, malignant disease of the bones); (*b*) the surgery of the bones, joints, muscles, and peripheral nerves: (*c*) the surgery of the limbs and spine.

I should like to point out that none of these definitions has any relation to the natural meaning of the word "orthopædic," and that the first covers more than half the field of surgery. I believe that in thus, at their own volition, extending the natural boundaries of orthopædics, orthopædic surgeons are weakening their position as specialists. If, as Mr. Elmslie says truly, it is impossible for one man to practise efficiently the whole of surgery, it is surely equally impossible for one man to attain the higher specialist skill over such a large part of that area as orthopædic surgeons now claim. For example, if bone tumours are removed into the field of orthopædics, and even Mr. Elmslie excludes other tumours from it, I doubt if these particular tumours will be as efficiently treated as by those who are familiar with malignant disease in all its forms.

There is, moreover, another aspect of this unfair extension of specialist claims. They amount in practice to an exclusive claim to the area thus fenced in. The general surgeon, who makes no exclusive claims for himself, is thus practically, though not formally, debarred from these areas because of the prestige attaching to the word specialist. Furthermore, as other specialties arise, each tending to enlarge its borders, the whole field of surgery will be divided into specialist areas, which, becoming contiguous, will proceed to overlap, and may finally coincide. In other words, the general surgeon will have returned under a specialist pseudonym, a result not dimly foreshadowed in Mr. Elmslie's letter.

It would surely be a misfortune of the first magnitude if surgeons broke up into competing specialist groups, each in fact practising general surgery but isolated from the other groups by a specialist designation. The exchange of criticism and of knowledge would be restricted and surgery would become a battle-ground of warring specialties. Mr. Elmslie feels that the field of orthopædics proper is too narrow. I suggest that the remedy for this cramped feeling is not the artificial extension of his specialty but that specialist appointments in orthopædics, which are undoubtedly necessary, should always be held in conjunction with a general surgical appointment. This should apply also to other specialties, but exception would have to be made for the eye, ear and throat, and for gynæcology.

The intensive study of particular fields of surgery by enthusiastic and able specialist groups has done much for surgery in orthopædics as in other departments and is a great constructive force. The indefinite extension of specialties will lead to disorganisation and anarchy; such, at any rate, is my belief. I would not presume to limit the range of the rivate activities of any surgeon, but I do think, for the reasons I have given, that specialists in council and in their public manifestations should confine themselves strictly within the natural limits of their specialty. The day when general surgery dies of inanition and when there is no common meeting-place for all those who practise it will be an evil one for our art. Personally, my view is that we should all be surgeons, without any adjective, though each of us may be known to specialise in some particular branch.

I am, Sir, yours faithfully,
W. Sampson Handley.
Harley-street, W., May 17th, 1926.

## THE ÆTIOLOGY AND TREATMENT OF CHRONIC RHEUMATIC DISEASES.

*To the Editor of* The Lancet.

Sir,—Having been precluded by the multiplicity of speakers from taking part in a recent discussion at Pistany, may I ask for space in your columns to express a British point of view a little different from that of Sir W. Willcox? Whilst believing in a determining *infective* factor in a minority of cases (a very small minority in the non-articular varieties), I regard the evidence of something like specificity in the *soil* as equally conclusive. Why do slight infections, traumatism, or exposure, to which we are all subject, evoke arthritis, fibrositis, &c., only in some individuals?

Men of large experience at the British spas, like F. G. Thomson at Bath, tell us that only a small proportion of cases of focal infection in teeth, tonsils, or urinary tract develop multiple arthritis. Dentists in large practice assure me that they have removed the teeth from numerous arthritic and rheumatic persons without any benefit. Dr. Tylor Fox informs me that, in South East Russia in 1917, the peasantry—

especially the young adults—were almost universally affected with pyorrhœa, although the teeth appeared to be in good condition. Very little rheumatism or arthritis was observed. They were an undernourished people in a time of scarcity, and in the best of times they led hard lives. Here it ought to be especially noted that extremely hot sweating baths were in general use among the population as in other parts of Russia. Rosenow is inclined to attribute the affinity of streptococci and toxins for the articular and periarticular tissues to failing nutrition and deficiency of oxygen in those tissues.

Why is a "cold in the head" followed in some persons by pan sinusitis? Why is influenza or pneumonia sometimes fatal in a few days? If some other factor than infection, some "specificity in the tissues," is at work in acute diseases, is it not equally present in chronic diseases? I submit that whilst treating ascertained sepsis in chronic rheumatism, as in other chronic maladies, we should never allow ourselves to follow a wild-goose chase after organisms, that we should remember that the governing factor in disease is not the presence of organisms but the power of resistance of the body to organisms, and especially that since chronic rheumatism, in some forms at least, has been proved to have a climatic distribution, we should endeavour in our treatment and prevention of rheumatism to compensate unfavourable climatic influences. My own conviction is that in many cases of rheumatism, as in tuberculosis, the best treatment is general and not local. At all events it seems rational that when the field of ætiology is wide we should try to advance along the whole front.

I am, Sir, yours faithfully,

London, W., April 27th, 1926. R. FORTESCUE FOX.

## HEALTH OF THE COAL MINER

*To the Editor of* THE LANCET

SIR,—My attention has been drawn to a leading article on this subject appearing in THE LANCET of April 10th. In the course of that article it is stated that:—

> "The mortality experienced by coal-miners is fairly low; yet the Lancashire miner, with the South Wales miner not far behind, has a mortality nearly double that of his fellow in the Nottingham area. *Now the Lancashire and South Wales miners have always manifested the greatest unrest as a class;* unrest in the industry appears therefore quite clearly as a psychological expression of ill being."

I can only suppose that this observation is based upon Table B in App. 32 on p. 326 of the Appendices of the Report of the Royal Commission. That table gives the following particulars of the Mortality of Coal Miners in Different Parts of the Country per 1000 Living:—

*Mean Annual Death rate per 1000 Population*

| | Years of age. | | |
|---|---|---|---|
| 1921–23. | 25–35 | 35–45 | 45–55 |
| Lancashire and Cheshire | 4·15 | 7·17 | 12·45 |
| South Wales | 4·18 | 6·94 | 12·30 |
| Derby and Nottingham | 3·46 | 5·38 | 9·80 |
| Yorkshire (West Riding) | 4·10 | 6·50 | 11·12 |

I cannot see that these figures bear out your contention that the mortality of miners in Lancashire is nearly double that of miners in Notts and Derby; and you seem to have disregarded the comparison with Yorkshire, which contains some of the most up-to-date collieries and the most modern mining villages in the whole country.

Nor does it seem to me that your argument as to the connexion between unrest and housing conditions is borne out by the evidence before the Royal Commission. In App. 35 on p. 330 of Vol. III of the Report it is stated that "with a county average of 5·9 per cent. of overcrowding the individual figures for St. Helens were 14·5 per cent. and for Wigan 10·8 per cent. But other mining towns, such as Farnworth and Chorley, had a percentage of overcrowding less than the county average." And I think it would be generally agreed that St. Helens is at least as much a chemical town as a mining town—if not more so. In fact, in Lancashire the miners are not isolated in mining villages to anything like the same extent as they are in other parts of the country, but live under housing conditions similar in all respects to those of the general working-class population.

Is it not probable that the explanation for the higher mortality, such as it is, in Lancashire is given in the passage in App. 32 on p. 325 of Vol. III that "we must not forget that the coal-mining industry is carried on in a part of the country where the mortality from these causes (bronchitis and pneumonia) in the general population is unfavourable—particularly in Lancashire"?

I am, Sir, yours faithfully,

PHILIP GEE.

King-street, Covent Garden, W.C., April 27th, 1926.

*** Our statement was based upon a comparison between (*a*) the comparative mortality figures issued by the Registrar-General in his Decennial Supplements dealing with occupations, and (*b*) the amount of unrest as measured by ballots of the miners taken on several occasions. The records which appeared in a letter to the *Times* of Jan. 24th, 1924, from Prof. E. L. Collis (who has considered the subject more fully elsewhere[1]) are as follows:—

| Coalfield. | Comparative mortality— | | | Percentage of miners that voted— | | |
|---|---|---|---|---|---|---|
| | 1890–92 | 1900–02 | 1910–12 | For strike, August, 1920 | Against resuming work, June, 1921 | Against wage agreement, Jan., 1924 |
| Lancashire | 1230 | 1000 | 941 | 90·6 | 89·6 | 94·3 |
| South Wales | 1322 | 951 | 774 | 77·9 | 73·0 | 89·8 |
| Yorkshire* | 1051 | 783 | 758 | 61·1 | 65·3 | 75·1 |
| Northumberland and Durham | 894 | 763 | 635 | 69·9 | 60·7 | 75·0 |
| Derbyshire | 841 | 676 | 591 | 71·8 | 52·7 | 76·8 |
| Nottinghamshire | | | 570 | 55·1 | 53·7 | 69·2 |

* The position of Yorkshire in 1920 may be noted; on this field a strike, which did not affect the rest of the industry, occurred in 1919 and was held to influence the vote of 1920. In 1921 and 1924 the percentages recorded placed this field not far from the position given by mortality.

In this connexion interest attaches to the mortality-rates on the coalfields for the years 1921–23, some of which are quoted in the above letter. These rates are not presented as comparative mortality figures, but nevertheless the order of the coalfields, arranged in accordance with these newer records, does not materially differ from that of earlier years.—ED. L.

## INSURANCE POLICIES IN CIVIL EMERGENCIES

*To the Editor of* THE LANCET

SIR,—With reference to Section 2 (*Accidental Damage*) of Clause 3 of the Doctors' Special Policy issued by Lloyds underwriters through the Medical Insurance Agency, the meaning of the words "and shall also indemnify the insured in respect of external damage to the insured car during riots and civil commotions" is undoubtedly that damage caused to any part of the car by external means is covered. It will be understood that mechanical breakdown is not covered either during riots or civil commotions, or during peace-time.

Such damage as (1) removal of carburettor, (2) puncture of petrol tank, (3) slashing of tyres

---

[1] The Coal Miner: His Health, Diseases and General Welfare. Journal of Industrial Hygiene, May, 1923.

(4) damage to glass, &c., of covered cars is insured under the policy.

If a car is not used for its normal purpose the policy will be invalidated unless previous notice has been given and the assent of the underwriters obtained. Thus, a 4-seater car could carry four passengers even though they be not personally known to the owner and the policy would remain in full force, but a private car is not normally used for the conveyance mainly of foodstuffs. Damage to springs due to overloading is not covered under the policy whatever the cause of the overloading may be. Such damage would come under the heading of mechanical breakdown, and would not be covered in any event.

It should also be noted that the holders of fire and burglary policies are not usually covered for damage by riots and civil commotions, and the same remark applies to "combined" household policies. It would be wise, therefore, for all insured householders to see that they hold "comprehensive" household policies of the type issued through the Medical Insurance Agency, in which case they will find their interests fully protected in the terms of the policy.

I am, Sir, yours faithfully,

L. FERRIS-SCOTT,

Secretary, Medical Insurance Agency.

B.M.A. House, Tavistock-square, W.C., May 11th, 1926.

## SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

THE annual general meeting of this Society was held on May 12th when the report for 1925 was accepted. The year has been memorable, for during it a letter was received from the Inland Revenue Authorities stating they much regretted that in future the Society could not be considered a Charity under the Finance Act and that consequently no further refund of income-tax would be made. At the present rate the tax would amount to £940. The secretary pointed out that this was the first time, since the foundation of the Society in 1788, that a refund had been refused, but was unable to get the decision altered. An appeal to the Special Commissioners heard last December was granted, but the Inland Revenue still dissented, maintaining that under the Finance Act the Society is not a Charity, though under Common Law it would be considered one, and asked the Special Commissioners to state a case for the High Court. As the Society's income for this year was diminished by £960 some reduction had to be made in the grants, and a Christmas present of £5 only was sent to each widow and orphan, instead of the amounts given last year—namely, £20 to each widow over 75 years; £15 to each widow under 75 years; and £10 to each orphan. Since the last report nine new members have been elected and seven have died or resigned. The Society now consists of one honorary member, 160 life, and 139 ordinary members, making a total membership of 300. The income from investments amounted to £3866. £297 was received from subscriptions and donations, £58 from life subscriptions, and £700 from legacies. The working expenses were £335. The invested capital now stands at £133,450. During the year two widows died and four came on the funds; on Dec. 31st there were 53 widows and seven orphans in receipt of grants. The amount given in grants was £4464. Membership is open to any registered medical practitioner who at the time of his election is resident within a 20-mile radius of Charing Cross. The annual subscription for a member who at the time of his election is under 40 years of age is 2 guineas; if over 40 but under 50, 3 guineas; and if over 50, 4 guineas.

---

THE Cambridge University Press (Fetter-lane, London, E.C.) announces the forthcoming publication of a book by Dr. Henry Head, consulting physician to the London Hospital and honorary Fellow of Trinity College, Cambridge, entitled "Aphasia and Kindred Disorders of Speech." It will be published in two volumes. Vol. I. contains an historical sketch, an account of the new methods of examination employed by Dr. Head, and the results of his clinical observations; further sections are devoted to the question of cerebral localisation of function and to novel theoretical conclusions as to the nature and causes of aphasia. Vol. II. is devoted to a series of clinical reports of cases, each of which illustrates one or more aspects of the problems dealt with in Vol. I.

# Obituary.

## WILLIAM JAMES MAURICE, B.M. OXF., M.R.C.S. ENG.

Dr. W. J. Maurice, who died at Reading on April 22nd, was the son of the Rev. Thomas Maurice and was born at Harnhill Rectory, Gloucestershire, in 1858. He was educated at Cheltenham, at Keble College, Oxford, and at St. Thomas's Hospital; soon after qualification he entered general and surgical practice in Reading. At the outbreak of the war Dr. Maurice, then senior surgeon to the Royal Berkshire Hospital, was given charge of the local surgical division, and in 1916 was appointed commandant of the Reading War Hospital. His success in this trying work was evidence of his tact and ability, and he won the admiration of those who came within range of his personality. "The influence of Maurice's early training was notable throughout the whole of his career," writes a colleague. "He was a devout churchman and showed his convictions in his daily life. Of great simplicity of character, he disliked everything which suggested pretence or display, and in his dealings with patients and with other doctors he was invariably trustworthy and straight. Of a tall and handsome presence and courteous bearing, his outward form gave fitting expression to his inward nobility. So strong and durable were his qualities that none appreciated them more than those who came most closely in contact with them. He was the perfect partner who won the affection and admiration of those who saw him as he really was. His work was always done conscientiously and with more than ordinary skill and ability, and while still an accomplished operator he gave up this part of his practice on the mere suspicion that he might be thought out of date or incapable."

Dr. Maurice's wife died some years ago and he lost three sons during the war. He leaves one son and two daughters.

## WALTER COURTENAY RIVERS, M.R.C.S. ENG., D.P.H.

Dr. Rivers, whose death occurred at his home, Worsboro' Bridge, Barnsley, on April 23rd, was a striking example of a man who in spite of ill-health and the need to earn his living contributed not a little both to literature and medicine. His student days were spent at the Charing Cross Hospital Medical School, where he was Roan Exhibitioner and silver medallist in medicine and whence he qualified in 1898, taking the public health diploma of the Irish Royal Colleges five years later. After assisting in the electrical department at Charing Cross Hospital and some surgical experience at the General Infirmary, Stamford, he went to the East as surgeon to the British and Colonial Steam Navigation Company, soon afterwards joining the Royal Army Medical Corps in India. In 1904, however, he was invalided home on account of pulmonary tuberculosis, and for more than 20 years his life was a struggle against disease. After four years of sanatorium treatment and intermittent temporary work he became medical superintendent of Barrasford Sanatorium, near Newcastle, and five years later accepted the position of tuberculosis officer to the Barnsley district of the West Riding County Council. In this murky mining locality he became greatly beloved by his patients for whom he worked unremittingly. Even those who met him casually soon found out how thorough, how thoughtful, how up to date was his work for the community. Rivers was well versed in general as well as in medical literature and in the special subjects about which he wrote. His work on the relation of tubercle to certain conditions such as squint will stand the test of time; he contributed to the Treasury of Human Inheritance on family phthisis, and wrote a number of articles on nasal defect in tuberculous subjects. His last book, "Through a Consulting-Room Window," is really brilliant. His literary style, distinctive and virile, reflects the thoroughness of German scientific workers for whom he had a profound admiration. He was a keen politician, an ardent socialist, yet also rather strongly anti-feminist, and a fervent pacifist. Though his outside interests were wide, his family life was happy and he was devoted to his wife and children. His health broke down seriously about two years ago, when the recrudescence of disease was stemmed only for a time by double artificial pneumothorax and by treatment with sanocrysin at a sanatorium in Denmark. But his joy of life lasted into almost the last stage of a long-drawn-out illness.

Of Rivers's intellectual equipment one of his friends writes: "His genius, and I use this word advisedly, was that of an angular character which requires to rub off its corners against kindred spirits in order to bring out the best of it. At Barrasford he was starving intellectually though he was an indefatigable student of men and books. The subjects on which he touched were many; the insularity of medicine in England, the stupidity or dishonesty with which new remedies for tuberculosis were launched without adequate investigation, the importance of German work on sex problems, and many others. His attitude towards life was one of quizzical, almost sardonic humour. Life had treated him hardly and he met his hardships not only with courage but with a smile. Had he enjoyed good health he would assuredly have made his mark either in literature or in medicine, for his literary gifts included a rare sense of the beauty of English, and his innate honesty and capacity for logical and consecutive thought would have carried him far in medicine."

## ROBERT HILL SHAW, M.D. DUB.

THE sudden death of Dr. R. H. Shaw on April 24th came as a shock to his friends, for he was attending to his practice up till the night before he died. Dr. Shaw had practised in Brighton for some 30 years and was one of the best known medical men in the town. Born at Ballymahon, Co. Longford, 66 years ago, he was educated at Trinity College, Dublin, and graduated in medicine in 1892, becoming M.D. Dub. six years later. He held several house appointments in Dublin before he went to Brighton, where he soon acquired a large practice. During the war he was granted a commission as captain in the R.A.M.C. and did good work at several of the large Sussex camps. In Brighton he was surgeon to the East Sussex constabulary and held other appointments; he did valuable work amongst the poor. In his leisure time Dr. Shaw found opportunity to contribute a number of papers to medical journals. He leaves a widow, a son, and a daughter. The funeral on April 28th was attended by 500 to 600 people representative of all classes in the town.

## THE LATE COLONEL C. A. JOHNSTON.

AN obituary notice of Colonel Charles Arthur Johnston, C.B., D.S.O., I.M.S. (retd.), appeared in THE LANCET of May 1st. We have received a personal appreciation from Sir Patrick Hehir, who writes: "Colonel Johnston was held in great respect by all who had the pleasure of working with him. We served together on several occasions, and he filled the place I was to have occupied at an early stage of the Great War—viz., A.D.M.S. of the Expeditionary Force to German East Africa. He was a splendid workman, most thorough and reliable, and a good and careful doctor. He had the exceptional faculty of making those who worked with him his personal friends and of getting the best work out of his juniors. He was a cheerful and interesting companion and a fine all-round sportsman. The severe and prolonged hardships he went through in East Africa undermined his constitution and, as he never spared himself, climate, defective food, exposure, and disease left their sting. His loss is deeply regretted by his many friends in and out of the service, who offer their deepest sympathy to his widow and son."

## HENRY RENNEY, M.D., D.HYG. DURH.

Dr. H. Renney, who died on April 24th, was born in Sunderland 66 years ago and was medical officer of health for the port and borough. He was destined to become an architect, but his thoughts turned to pharmacy and then to medicine, and after studying at the College of Medicine, Newcastle, he graduated in the University of Durham in 1880, proceeding to the M.D. degree two years later. After a number of house appointments at Newcastle and elsewhere he settled in general practice at Sunderland, acting as deputy to the medical officer of health until 1904, when he succeeded Dr. Harold Scurfield on the latter's appointment to Sheffield. In 1908 he became doctor of hygiene in the University of Durham. Dr. Renney was a hard-working and conscientious man with a thorough knowledge of his work. He started a system of voluntary notification of tuberculosis in Sunderland and was responsible for the appointment of a woman health visitor at a time when this was very unusual. Taking a great interest in the Northern branch of the Society of Medical Officers of Health, Dr. Renney was at one time its president. He was also a Freemason and a keen student of Greek. He leaves a widow and two sons.

## ARCHIBALD BURNS GEMMELL, O.B.E., M.R.C.S. ENG.

ON April 28th Dr. Burns Gemmell died at his house in Liverpool after a long illness. He was the son of Dr. Gemmell, of Dunoon, Ayrshire, and practised in Liverpool for many years. Qualifying in 1883, he became house surgeon at the Western Infirmary, Glasgow, and then spent some years in Burma. Long before the war he was closely associated with the R.A.M.C., and in 1913 he was appointed commandant of the 1st Western General Hospital. In this capacity he was soon to have his organising powers fully tested. At the beginning of the war the unit adopted the infectious diseases hospital, Fazakerley, as its headquarters and the personnel was expanded to include a large number of Liverpool doctors. Lieut.-Colonel Gemmell became responsible for the supervision of military hospitals over an area stretching from south of Shrewsbury to north of Carlisle. His duties were carried out with success for he was an excellent administrator. During part of the war he did similar work in France, commanding the 57th General Hospital of the British Expeditionary Force. He leaves a widow, a son, and a daughter.

## THE LATE DR. FREDERICK PALMER.

IN supplement to the obituary notice published in our issue of May 1st, Dr. Harry Campbell has sent us the following appreciation of his colleague's work: "Dr. Frederick Palmer's sound practical knowledge gained at the Radcliffe Infirmary, where he was resident for some years, coupled with his natural gifts of energy, kindness, geniality, tact, business instinct, and personal charm, were bound to secure for him a prominent position in the profession. The courageous step he took, when well advanced in life, to abandon general practice and begin consulting practice in London was thoroughly justified by events. The wisdom of his election as physician to the West End Hospital for Diseases of the Nervous System was proved by many years of skilled and devoted service, and by the affection he inspired in all connected with the hospital. Dr. Palmer faithfully obeyed the admonition 'Judge not'; I never knew him either directly or by veiled innuendo to cast aspersions on others. He was happy, serenely happy, in his home life, and was fond of music, history, and biography. Golf he never succumbed to, but many an off afternoon was spent in walks round and about London with his long-time friend, Dr. de Havilland Hall. Though advanced in years, Dr. Palmer was singularly youthful in mind and body, and it was a great grief to his many friends when they learnt that he had fallen a victim to an attack of virulent influenza."

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS.

### Welfare Centres and Birth Control.

In the House of Lords on Wednesday, April 28th, Lord **Buckmaster** moved :—

> "That His Majesty's Government be requested to withdraw all instructions given to, or conditions imposed on, welfare committees for the purpose of causing such committees to withhold from married women in their district, when sought by such women as to the best means of limiting their families."

He said that the subject of his motion was one of the large group of new grave questions that were pressing upon the country with increasing insistence, and which demanded the rational, restrained, and intelligent discussion which could be obtained nowhere better than in their lordships' House. Some 50 years ago this question was new. Its advocacy was attempted to be punished by the Criminal Law; it startled and shocked people, but to-day the only question left was this: Will you take steps to withhold from the poor the knowledge possessed and practised by the rich? They could not read any books dealing with this question—and he had read many—without finding that they treated it as an accepted axiom that birth control was being extensively practised by the well-to-do classes, and that it was only among the poorest, the most ignorant, the most destitute, the most shiftless, helpless, hopeless stratum of society that that knowledge was not used. Statistics were eloquent on the point. If they took 1000 married people under the age of 50 the birth-rate for schoolmasters was 93; for clergymen of the Church of England it was 100; for clergy of all denominations it was about 102; for doctors and professional men it was from 103 to 105; for skilled labour 153; and for unskilled labour 247. If they took the standard of intelligence measured in the same way by examination of the children in the schools they would find that there was a descending scale of intelligence which was in the exact inverse ratio to this standard of birth-rate. In spite of what people might say about the nation being divided into classes there was continually going on the winnowing process of nature, and in the great solution of life every organism took its proper place according to its specific gravity. The people for whom he spoke represented the lowest sedimentary stratum of all. In these circumstances he asked why was it that this knowledge was withheld from them?

The present position was this: The Ministry of Health would provide money to assist welfare centres set up by local authorities to enable the centres to give help and advice to women who were expecting children and to women who had young children under their care. But there was an expressed prohibition that prevented these people, though they were qualified medical men and women, from being able to give information to any person who asked how further births could be prevented. The question before their lordships was whether that state of things ought to be allowed to continue, not merely in the interests of justice, but in the interests of our race. There were people who deplored the fact that birth control was practised by the well-to-do. But it was no use weeping over lost battlefields; that struggle had been fought and it had been lost and won, and they could never recapture the position. The reason was not that women were selfish and men were worthless or that the world was addicted to nothing but pleasure. It was due to a much higher and more permanent cause than that—namely, the desire of parents to secure that their children were not pressed out by the illimitable competition of unrestricted numbers, and to the hope that they would be able to make for their children an easier and better place in the world than they themselves had filled. People who talked about the ennobling effect of struggling with poverty had never known the struggle, which was the most degrading and demoralising struggle to which any human being could be subjected. Let their lordships note that his motion laid no burden and imposed no duty on any medical officer of health. It did not even say that in the opinion of the Ministry of Health it ought to be done. But it was to let these qualified people, if they in their judgment thought fit, exercise their medical knowledge for the relief of the women that came before them.

Proceeding to give examples in support of his case, the noble lord instanced a woman who was married at the age of 17. At the age of 34 she had had 18 pregnancies with 11 live children. Her husband, a hawker, was often away from home and did not attempt to support the family. The mother did this by hawking. The housing accommodation was one living-room and two bedrooms. The mother shared a flock mattress without sheet or blankets with the youngest children, and her last confinement was conducted under these conditions. The mother and all the children were clean and well-cared for. She refused to have relation with her husband until he overpowered her, and, of course, by the merciful law of this country a man could not rape his wife. She had asked him to take other women. During the last pregnancies she had done everything she knew to procure abortion. She could not go away from home. That case was by no means unusual, and such cases would continue if they did not enable these women to obtain knowledge of birth control. They all admitted that they made repeated and frequently successful efforts to procure abortion. He could not help thinking that they lived in a world of sham or in a cloud-cuckoo land. Every now and then cases came before the courts and some person was sent to gaol for a long period of years for performing an illegal operation. But that was the commonest thing in these places; the women were driven to resort to it as the only means of escape from a state they found to be intolerable. But when they came and asked the medical officer of health how they might prevent themselves getting into the same condition again the officer said: "No; if I venture to tell you anything of the kind the Ministry of Health would stop the grant for this centre, and we shall not be allowed to continue." Probably the saddest story of all was this:—

> "When we first knew this family they had four children, all of whom had been born without eyes. The two eldest had died when quite small, and two little girls, aged 2 and 4, had managed to survive. The mother was suffering from dementia præcox, and spent 18 months in hospital. She was incapable of training the children, who, sightless and speechless, sat all day long in their little beds manifesting not a single normal reaction to the tests that were given. The father was devoted to the mother and refused to send her to institutions, but, realising that she ought not to have any more children, begged the information by which he could prevent such a result."

All such women could be told was: "If you want information you will find a shop not far away with unclean pictures in the window and every suggestion of prurient and filthy literature inside. Go there, and they will probably be able to tell you, and it is perfectly certain that they will give you information that may be most deleterious to your health, and you will certainly not be under trained medical supervision. But it is not for us to help you." He really was anxious to know what was the answer to the case he had put. He asked that duly qualified medical men and women should not have their discretion fettered as to the way in which they should give advice to people who sought their help. Children could no longer be made instruments for the production of profits in a balance-sheet. It was said that directly they limited the birth-rate they began to descend in the scale of the world. Was the measure of nations to be tested by their fecundity as they tested the value of rabbits? It was not a question of numbers, but a question of quality. Numbers would not win the next war, but brains. At the moment there were just on a million people unemployed in the country. Did anyone think that in present conditions they could absorb these people in industry within a measurable period of time, and if so, were they going to absorb the over-flowing increase of the population? Last year the population increased by 247,000 people, and before that the increase was larger still. Within the first 20 years of the century we added more to the population than during the whole eighteenth century. Those who held that it was for the public good that the population should increase at that rate must take the responsibility for the consequences which must inevitably occur. With all due respect he found himself quite unable to understand what was the ground on which religious objection to this principle was based. All attempts artificially to prevent the natural consequences of relations between man and woman had been condemned by a group of eminent ecclesiastical authorities at Lambeth. They did not say that blind, syphilitic, tubercular, and mad children must be reproduced, but they said that the right course for a man or woman to follow was to exercise self-restraint. What a strange doctrine to preach to people who lived under the conditions he had described! Human nature being what it was this doctrine of abstention was impossible. There were occasions when he felt that if he stood alone in the world he would protest against the doctrine that there was something in itself that was evil in the relations between man and woman. If that were true, evil was to be found in the very centre of all beauty, of the blossom of life. This doctrine that people should abstain from these relations was wrong and mischievous, and was certain to lead to the shattering of more homes than any of the causes they had heard denounced in that House.

The **Marquess of Salisbury** (Lord Privy Seal) said he would be very sorry if a mistake were made by their lordships that afternoon, because what was really concerned was the success of the great policy of hygiene which had been the characteristic of the last half century in this country, and which had met with such success. Everyone would sympathise with the wretched cases of misery and sorrow mentioned by Lord Buckmaster and would do their utmost to prevent them. But they must be very careful indeed that in finding a remedy for the evils he had detailed they did not strike a fatal blow at a great service which was doing infinite good to the very class for which Lord Buckmaster pleaded. The maternity and child welfare system had been in existence for a number of years and had grown enormously. There were over 400 maternity and child welfare committees, sometimes of the county councils and sometimes of the lesser local authorities. There were over 2000 centres scattered all over the kingdom. Apart from the official personnel there were a large number of voluntary workers whose support was absolutely vital to the success of the system. There were, roughly speaking, 700,000 mothers who bore children each year. Of those upwards of one-third probably took advantage of these maternity centres, and the success of the movement had been very great. The mortality among children under 1 year had gone down by 50 per cent. since 1900. Unless Lord Buckmaster was very careful he would strike a fatal blow at this great system, because he was proposing to bring within its purview a subject which was alien and in the highest degree controversial. Birth control might be useful; it might be necessary; but the kind of people who were interested in one were not necessarily interested in the other. He had made some little inquiry, and he had found that to bring this subject within their purview would profoundly shock a very large number of those who were engaged in this voluntary work. It was not only religious bodies who were opposed to it. He had received a resolution from the Mothers' Union, which represented a very large number of women of the lower class. That resolution, drafted in strong terms, urged their lordships not to pass Lord Buckmaster's motion. If they did anything that would interfere with the success of these centres they would be extremely rash. It was for that reason in the main that the Government could not support the noble lord's motion. The movement for birth control was not confined to people whose health dictated that they ought not to have any more children. Everyone knew that the movement was largely supported by women who could have children, but who preferred not to have them—married women who did not do their duty and preferred their own ease to the obligations they had undertaken. They might be deeply sorry for the unfortunate, the wretched, and the miserable women, but they had no pity whatever for the lazy and the vicious woman. How could the medical officers at these centres discriminate in regard to giving this information?

Lord BUCKMASTER: Why not? Private doctors do.

The MARQUESS OF SALISBURY said that might be so, but this was not a private doctor. It was quite impossible for the doctors at these *centres to make* any distinction. And in the case of these indolent women of whom he had spoken ought the husband not to be considered? Poor women could go to doctors just like richer people, and it was a great mistake to suppose that they were utterly ignorant in these matters. For a relatively small fee they could go to the doctors whom they generally consulted. But however that might be, he asked their lordships not to allow the hard cases to influence them too much. Lord Buckmaster seemed to regard the fall in the birth rate as rather a good thing. He (Lord Salisbury) thought it was a very serious thing. The more healthy English men and women who were produced the better, in order to populate not only this country, but the Empire. In the decade 1871 to 1880 the births were 35 per 1000. In 1921 they were only 18 per 1000. The reason that the population was increasing was on account of the shrinking death rate. Birth control methods were most popular in France and the population of that country was going down. The real catastrophe in front of European civilisation was that the white races would begin to diminish. This was not true yet of the Slavs, but the ratio of increase in Germany was receding, as was also the case in Britain. In that direction lay national death. He appealed therefore to their lordships not to lend any countenance to the official sanction of birth control with all its dreadful suspicion.

The ARCHBISHOP OF CANTERBURY said that of these maternity and infant welfare centres there were 2122 in England to-day and at 611 of them pre-natal work was carried out. Prior to the formation of such centres the death rate among children under 1 year was very high. In 1905 it was 128 per 1000, in 1910 it had fallen to 110, and it was now 75 per 1000. That fall went far to conceal or disguise a rapidly *falling* birth-rate. In addition to these subsidised maternity and child welfare centres there were now in England a good many birth control clinics, established wholly by voluntary agency and supported either by voluntary subscriptions, or by the fees of the patients, or by both. He made no suggestion that there should be any restriction or interference with these birth control centres which were supported by some exceedingly thoughtful people. But Lord Buckmaster asked why the advice given there could not be given in all the welfare centres. He knew very well medical men and health visitors who were at work in some of the large centres, and he had made inquiries from them on this matter. He found a perfect assurance everywhere: firstly, that the applications for advice of that particular kind was not unknown but rare; and secondly, that no restraint whatever was put upon the doctor if upon medical grounds he thought it necessary to give advice respecting child-bearing, but he was under no obligation to give such advice. Surely that was right. If they looked at the rules which the Ministry of Health issued they would see that—

"Collective teaching may be given either on the consultation day, when most of the mothers will be present, or on other days for women who wish to learn about some special subject. On consultation days the teaching will usually be limited to short, simple 'health talks' by the superintendent on subjects of general interest, and accompanied, when possible, by practical demonstration."

He wished their lordships to realise that if they passed the noble lord's motion they laid upon these men who were public officers a moral obligation to give that advice to groups who asked for it. The two regulations which did exist and upon which the noble lord's motion rested were as follows:—

"(1) That the maternity and infant welfare centre should deal only with the expectant or nursing mother (and infant) and not with the married or unmarried woman contemplating the application of contraceptive methods.

"(2) It is not the function of an antenatal centre to give advice in regard to birth control, and exceptional cases where the avoidance of pregnancy seems desirable on medical grounds, should be referred for particular advice to a private practitioner or hospital."

He did not think that the second of these two rules was worded in the best way, but the medical man or woman needed in his judgment to be protected against having that moral obligation laid upon him or her to give advice upon this subject of contraceptives, which he or she might not wish to give, and which those who were supporting and guiding the centre did not wish should be given. In order *to satisfy himself* he made inquiries from some of the highest authorities in the Ministry of Health and he asked their lordships' attention to a memorandum which he had drawn up from the conversations he had had with those authorities:—

"In all cases attending the clinics where this information is necessary on medical grounds advice is always given by the doctor irrespective of any request on the part of the mother. Neither by the wish of the mother *nor by statistical* evidence have we been led to believe there is any great demand for this kind of advice. In suitable cases recommendations have been strongly made that the use of *contraceptives* should be discontinued, and we have reason to know that the advice has been acted upon with satisfactory results.

"The extreme medical cases in which another birth would be likely to prove disastrous to the mother are few and far between. Such cases would not ordinarily attend a maternity and infant welfare centre, but if and when they did it may be safely assumed that the mother would be advised as to the right course to adopt in order not to have any more children. The purpose of the maternity and infant welfare centre is to deal only with the expectant or nursing mother (and her infant), and not with cases of disease on the one hand, or, on the other hand, with married or unmarried women contemplating the application of contraceptive *methods*. The object of these centres is: (1) to advise the expectant and nursing mother; (2) to provide antenatal supervision, and (3) to care for the infant. In order to conserve the purpose of these maternity and infant welfare centres it is necessary to exclude any systematic or organised work in the direction of contraception."

It was made perfectly clear that no sort of restriction was placed upon medical men. He asked further whether if the medical man or woman did give this advice it would mean either the withdrawal of the grant or discredit to the individual. The idea was laughed at. If, therefore, the Ministry of Health would revise the wording of the second regulation that would practically knock the bottom out of the grievance which was supposed to exist. There was no desire to intervene between *doctor* and patient, but the medical officer did not wish to be morally forced to give such information against his or her will. Not only was there the widest possible difference of opinion on the ethical side of the question, but what about medical knowledge? He had had talks with Lord Dawson of Penn about it and had read the evidence which he had given on the subject. Lord Dawson of Penn said:—

"Up to now there has been no systematic investigation of contraceptive methods by the medical profession in this country, though such an investigation is now proceeding in the United States."

With such testimony as to the present uncertainty of knowledge on the subject it would be intolerable to lay upon the medical authorities the duty of giving such advice.

Lord BALFOUR OF BURLEIGH said that misapprehension had arisen owing to the words in the official rule about "exceptional cases in which avoidance of pregnancy seems desirable on medical grounds." He believed that those words referred definitely and rigidly to cases in which a further pregnancy would definitely mean danger to the life of the mother. He was told that it meant one of two things—either a particular form of disease of the kidneys or else a physical condition which was known as restricted pelvis. Lord Buckmaster wanted information given in cases where there was disease, say tuberculosis or venereal disease, and where children would be born diseased. It was suggested that women might apply to a hospital or a private practitioner, but in the out-patients' departments of the big hospitals they would not, or could not, give this information, and women of this class had usually no private doctor. These centres knew all about the women who came to them. Each had a qualified medical officer in charge and health visitors who visited the women in their homes and followed up the cases. It was obvious that that was much better machinery for disseminating this information than a birth control clinic. In Holland information about contraceptive methods had been placed at the disposal of the poorest people for the last 30 or 40 years. It was true that the birth-rate in Holland had fallen, but not anything like so much in the educated classes as it had in this country. What could be a greater recruiting agency for Bolshevism than the irresponsible and ignorant propagation of the unfit as it was going on to-day in the slums of our industrial cities?

Viscount Fitzalan of Derwent submitted that no Government would be justified in acting on a motion of the kind moved by Lord Buckmaster unless they were satisfied that there was, at any rate, more or less unanimity in the medical profession with regard to it. He had a list of names of eminent physicians who were all against these proposals connected with birth control. They were Dr. H. R. Andrews, senior obstetric physician, London Hospital; Dr. Hector Cameron, physician to Guy's Hospital; Mr. Bellingham Smith, senior obstetric surgeon to Guy's Hospital; Dr. Ernest Ware, senior surgeon, Hospital of St. John and St. Elizabeth; Dr. A. E. Giles, senior surgeon, Chelsea Hospital for Women; Dr. R. A. Gibbons, physician to the Grosvenor Hospital for Women; Dr. F. J. McCann, surgeon to the Samaritan Free Hospital for Women; Lady Barrett, Dr. Mary Scharlieb, and Dr. Louise McIlroy. Last July the welfare group of the Society of Medical Officers of Health at its annual meeting debated this subject. Dr. Letitia Fairfield urged that the removal of the ban of the Ministry of Health would inevitably split the child welfare movement from top to bottom. It was significant that the whole of this question was debated at that meeting, and although there was undoubtedly considerable medical support no resolution in favour of birth control was passed. He would quote from The Lancet of May 14th, 1921. Dr. Giles was reported as saying that he wished the opinion to go forth from the Obstetric Section of the Royal Society of Medicine that the use of contraceptives was a bad thing. He would also like to quote Dr. Robertson, medical officer of health for Birmingham, who said in his annual report for 1924 on the question of artificial birth restrictions :—

> "Its public health importance largely centres round the fact that already in a certain number of cases most mischievous results have come to light in Birmingham, due to the fact that methods of birth control are becoming widely known to many young people, who, as a result, indulge in promiscuous intercourse with the knowledge that no inconvenient result will follow."

Dr. McCann was reported in the *Pall Mall Gazette* of Jan. 31st, 1923, as saying :—

> "Besides being the wrong method of dealing wih the question of birth control, contraceptives are dangerous and harmful to any woman who would use them. There is, in my view, not one of these appliances that is not either injurious or unhealthy. It is a truism to say that one should not interfere with nature, but it is one which many people have forgotten. The extensive use of these things invariably produces some form of ill-health, together with a general distress of mind."

Allusion had been made to France, but it had not been pointed out that the French Government five or six years ago found it necessary to forbid by law the use of contraceptives. No Government would have passed a law like that unless they had felt bound to do so for the safety of their country. He could not see how any British Government with the smallest germ of patriotic feeling could possibly, after the example of France, take the smallest step to advertise methods of this kind. As an Englishman he protested against any such step which he was firmly convinced would let his country down.

Earl De La Warr said that in his view not a single argument put forward by Lord Buckmaster had been touched or answered. He thought it was for their lordship's House, quite irrespective of what the House of Commons did, to recognise a good wholesome social tendency when it appeared, and instead of turning their backs on the forces of science which made the realisation of that new spirit possible, to meet and to utilise them for the good of society.

Lord Rathcreedan, in supporting the motion, said that medical science would continue to advance, and those who were in a position to do so would take advantage of that science. Were they going to deny it to the poorest classes of the community?

Earl Russell also supported the motion. He said he was acquainted with one of the birth control clinics—the first that was founded by Dr. Stopes. The rule there was that no birth control advice was given to newly-married women, but only to married women who had already had one child. He profoundly disagreed with the idea that it was the duty of women to bear children because their husbands desired it, or because it was for the good of the country. The time had passed when woman was to be regarded as a serf, either of her husband or of the State. He did not think that the most ardent advocates of birth control had ever contended that any perfect methods had yet been devised, or that there were any methods that were entirely free from objection. That was true of many other branches of medicine, if not of most of them, but the fact that they knew very little about cancer, for instance, was no reason for not using the best medical knowledge that was available.

Lord Wrenbury said that every noble lord who was going to vote on this motion must make up his mind upon this: Ought a medical officer at any of these centres to be placed in such a position that he must refuse to give applicants information which he knew would be of use to them. It appeared to him that it was the duty of everyone if they had knowledge which was useful, to promulgate that knowledge to the best of their power, and to run the risk of somebody abusing it.

The Lord Chancellor said their lordships were not asked to express any opinion for or against birth control, nor to say whether propaganda in favour of birth control should or should not be lawful. Welfare centres were formed to deal with cases of childbirth and for no other purposes. The resolution was not confined to women who sought advice on the ground of health. It would empower any member of the committee who had no medical knowledge to give women advice. The Ministry of Health intended that any cases where it appeared to the committee that further conception might be dangerous to the life of the woman or might destroy her health should be referred to the medical adviser. They were bound to insist that the advice must be medical, but it might be given by a panel practitioner.

On a division the motion was agreed to by 57 votes to 44.

### *The Economy Bill.*

On Tuesday, May 11th, the House of Lords went into Committee on the Economy (Miscellaneous Provisions) Bill. After a number of amendments, moved on behalf of the Government to carry out promises made during the passage of the measure through the House of Commons had been agreed to, the Committee stage was concluded and the Bill was reported to the House.

### *Midwives and Maternity Homes Bill.*

In the House of Lords on Monday, May 17th, the Midwives and Maternity Homes Bill (which has passed through the House of Commons) was read a second time.

## WORKING HOURS AND INDUSTRIAL FATIGUE.

On Friday, April 30th, in the House of Commons, Mr. Mackinder, a member of the Labour Party, moved the second reading of the Hours of Industrial Employment Bill, a measure the central idea of which was to establish a 48 hours week for all persons employed in industrial undertakings. He said that the Bill did not include all workers—hundreds of thousands, if not millions, of people were outside its scope—but the desire of the Labour Party was to secure that the word and bond of Great Britain should be kept as regards the ratification of the Washington Convention, and he looked to Parliament at some future date to pass similar legislation for the protection of all the workers in the country. Mr. Short seconded the motion for the second reading. Major Kindersley moved the rejection of the Bill, and Mr. Lloyd seconded.

Dr. Drummond Shiels, in supporting the measure, said that in the last report of the Industrial Fatigue Research Board for 1924 there was an account of an investigation into the significance of output in industrial efficiency by Dr. Vernon. Speaking of output he said :—

> "The writer found that when men and women engaged in making various fuse parts had their hours of work reduced from about 74 a week to 64 a week, and subsequently to 55 a week, their working speed improved considerably with each reduction of hours, but that it took three or four months before it obtained equilibrium with the shortened hours. For the first week or two after the change of hours, there was little or no response, and then the output, reckoned per working hour, began to mount up steadily till finally it reached a point at which it more than compensated for the loss of working time, and the total output each week was higher than before."

In regard to the sickness rate this investigator said :—

"During the war I collected sickness figures at three large national shell factories over an 18 months period, during which the hours of work were changed considerably by the adoption of various shift systems. The time lost by sickness and other avoidable causes was carefully separated, and it was found that the sickness time fell off steadily the shorter the duration of working hours. The women when working for 62, 54, and 44 hours per week lost respectively 6·1, 4·3, and 3·1 per cent. of their time whilst the men, working for 64 and 54 hours per week, lost respectively 5·7 and 4·0 per cent. of their time. During the last three years I have collected sickness data at several factories, and have always found it to be less than the figures quoted. For instance, at a tin canister factory where 1000 women were employed, only 2·1 per cent. of working time was lost by sickness between September, 1922, and August, 1924 and at a large boot and shoe factory the women in 1922–1923 lost 2·6 per cent. of their time from sickness and the men 1·8 per cent. of it. At both these factories a 44 hours week was being worked."

Whether they had tariffs against them, or whether they had continental competitors working under various advantages which this country did not possess they were faced, said Dr. Shiels, with the fact that the maximum efficiency of workers was given when a week of not more than 48 hours was worked. Dr VERNON also said :—

"Evidence of another kind was obtained by Mr Bedford and myself in several industries—carton making, labelling, shoemaking—where short time was in force. The workers were usually on an eight hours day, but when on short time they put in only three, three and a half, four, four and a half, or five days a week. We found that as the number of working hours increased the speed of production increased likewise till it attained a maximum with a working week of about 40 hours."

He (Dr. Shiels) thought that was an important point to note. The report continued :—

"With longer hours still it fell away, and it was 2 per cent. less per working hour when a 44 hours week was being worked and 4 per cent. less with a 48 hours week."

These quotations showed, while even the fairly considerable extent of the investigations could not be regarded as making them absolutely authoritative, that even less than the number of hours stated in this Bill probably gave the maximum efficiency and output. Therefore if this Bill were passed it could not be argued on scientific grounds that the working efficiency of the country would be reduced He hoped that the Bill would not only be read a second time, but that the Government would take it over

Dr VERNON DAVIES said that when the Labour Party first brought in the Bill he spoke and voted in favour of it. Having been connected with an industrial constituency for over 20 years, both as a medical practitioner and as a factory surgeon, he had an intimate knowledge of the working lives of the people, and therefore he felt that he might give the House some of the benefit of his experience. Having done so he thought that the House and the Labour Party in particular would have been satisfied with the gesture then made and would not have brought the Bill forward again this year He regretted that they had done so, because he thought that the present was a most inopportune moment. They had heard from several speakers that already 90 per cent of the workers of the country were working eight hours a day or less, therefore even if this Bill received its second reading it would not produce very much difference in the situation. Bearing in mind the recent conference held in London by the Minister of Labour with some of the Labour Ministers of foreign countries at which an agreement was come to which led them to hope that in a very short time the ratification of a 48 hours week would be an accomplished fact, he thought that the Labour Party might have trusted to the honour and honesty of the British Labour Minister and the Labour Ministers of foreign countries in this matter By improved management on the part of employers the necessity for the hours fixed in this Bill would not be quite so marked, because improved organisation would mean reduced hours. The old fashioned employers would be eliminated by modern competition unless they brought their equipment, plant, and management up to the state of modern efficiency He would suggest to employers that one of the first essentials for them was a scientific investigation into hours of labour and their bearing upon production It did not necessarily mean that the same hours of labour were best for all industries. There should also be a scientific investigation into the very important question of fatigue They had to remember three axioms If they had no health they had no energy if they had no energy they had no output and if they had no output they had no profit. Experiments had shown that in many industries a reduction of hours had been followed by increased production. Speaking generally, the more the human factor came into the question the more benefit was obtained from the reduction of hours, while the more the machine was considered the less the benefit was. The economic maximum of hours depended first of all upon the strain involved in the work It depended also upon the extent to which the work was governed by the pace of the machine Different rates of working meant different rates of strain. Then they had the factory environment—temperature, ventilation, and so on—the age and sex of the workers, factory organisation, such as welfare work, the food of the workers, and other factors. Welfare work was an economic advantage to most businesses. Fatigue was a most important point because it would have a very great effect upon the future of industry Fatigue was simply the result of activity which showed itself in a diminished capacity for doing work. The worker might be putting in the same number of hours, but actually producing less. The great test for fatigue was first diminished output, and secondly loss of health and increased liability to accidents, and above all nervousness and irritability on the part of the worker Fatigue was primarily a nervous, a psychological element. It was not necessarily muscular, because by the time that the stage of muscular fatigue was reached things were very far advanced. The point of his argument was that from the economic aspect alone it would pay the employers of the country to inquire seriously into the health of their workpeople and to see that the hours worked were economically the best.

Mr BETTERTON (Parliamentary Secretary to the Ministry of Labour), speaking for the Government, said that the Washington Convention without the agreement come to recently at the International conference of Labour Ministers in London was as unacceptable as it ever was. One of the points to be considered was whether the London Agreement could be rendered an effective instrument equally with the Washington Convention. That was a matter of considerable difficulty and might require consultation with other interested States. For these reasons it had not been possible for the Government to reach a decision on the subject. He asked the Labour Party to consider whether in the present circumstances they might not be seriously prejudicing the very objects they had in view by forcing a decision on that Bill that day

After further discussion Sir R. SANDERS moved the adjournment of the debate which was carried by 186 votes to 119

### *The Coroners Bill.*

On Wednesday, May 12th, the Coroners (Amendment) Bill was read a second time.

---

## HOUSE OF COMMONS

### THURSDAY, APRIL 29TH

### *United States and Service Disability Claims*

Major COHEN asked the Minister of Pensions whether he was prepared to follow the example of the United States of America, which allowed ex Service men suffering from tuberculosis, neuropsychosis, paralysis agitans, encephalitis lethargica, and amœbic dysentery to receive pension provided they could prove the service origin of such disability, irrespective of the date on which the claim was submitted.—Major G C. TRYON replied : If, as I gather, my hon and gallant friend is referring to the preferential terms given to the diseases specified by Section 200 of the World War Veterans Act, 1924, it is not correct to state that such preferential terms are accorded "irrespective of the date on which the claim is submitted." By the provisions of the section these terms were only accorded to men who showed, prior to Jan. 1st, 1925, that they were suffering in an appreciable degree from these disabilities. I am not prepared to recommend that the provisions for war compensation adopted by this country should be modified on the lines suggested.

### *Drugs Supplied to Panel Patients.*

Colonel DAY asked the Minister of Health whether it was proposed to hold an inquiry as to the purity of drugs supplied to panel patients.—Mr N CHAMBERLAIN replied : Arrangements have already been made and are now in operation for the systematic analysis of sample prescriptions with the object of testing the purity of ingredients and the accuracy of dispensing I see no necessity, therefore, for such an inquiry as the hon. Member suggests.

### TUESDAY, MAY 11TH.

### *Influenza Deaths.*

Mr NEVILLE CHAMBERLAIN (Minister of Health) informed Mr Day that 244 deaths were certified as being due to influenza in the administrative County of London during January, February, and March last Of these 6 were under the age of 1 year, 18 between 25 and 35, 20 between 45 and 55, 40 between 55 and 65, 48 between 65 and 75, and 53 from 75 years and upwards.

### *Indian Medical Service*

Mr LANSBURY asked the Under Secretary for India as the appointment to the post of Surgeon General of Madras was made by the Government of India from the All India list, why, in view of the fact that health was now a transferred subject, the appointment was not left to be made by the Government of the Madras Presidency.—Earl WINTERTON replied that the Indian Medical Service, being an All-India Service, was a central subject. To safeguard the position of the members of the Service, it was provided in the Devolution Rules that a local government should employ such number of Indian Medical Service officers in such appointments and on such terms and conditions as might be prescribed by the Secretary of State in Council. Among the posts reserved for the Indian Medical Service under this rule was that of surgeon-general with the Government of Madras, and one of the conditions prescribed by the Secretary of State in the case of this and a small number of other high posts was that they should be filled by nomination by the Governor-General. The object of prescribing this condition was to safeguard the interests of the Service as a whole, and the claims of officers not serving in the particular province concerned.

### *Ultra-violet Radiation in Scotland.*

Sir J. GILMOUR told Dr. Drummond Shiels that facilities for the treatment of tuberculosis by ultra-violet radiation (light treatment) had been provided or were in course of being provided by each of the four large cities in Scotland, the Middle Ward District Committee of Lanarkshire, the burghs of Greenock, Paisley, Motherwell and Wishaw, Coatbridge, Falkirk, and Kirkcaldy, the county council of Ross and Cromarty, and the following combinations of local authorities: the Fife and Kinross Joint Sanatorium Board, the South-Eastern Counties Joint Sanatorium Board, and the Dumfries and Galloway Joint Sanatorium Board. The facilities so provided by local authorities were, by arrangement, in some instances available for neighbouring areas, and the facilities provided at certain voluntary institutions were also available to local authorities. The nine first-mentioned local authorities and the burgh of Kilmarnock also provided, or were in course of providing, light treatment in connexion with their schemes of maternity service and child welfare.

## WEDNESDAY, MAY 12TH.

### *Pneumothorax Treatment by Local Authorities.*

Dr. SHIELS asked the Minister of Health how many local authorities in England and Wales made no arrangements for pneumothorax treatment and X ray screen diagnosis in connexion with tuberculosis schemes.—Mr. NEVILLE CHAMBERLAIN replied: In England, out of the 152 local authorities concerned at least 115, according to the information in my department, make arrangements for X ray examinations, and at least 50 have arrangements available for pneumothorax treatment. It is possible that such arrangements exist in some of the other areas. In Wales arrangements for both purposes have been made by the Welsh National Memorial Association, with whom all the local authorities concerned in Wales contract for the provision of treatment for tuberculosis.

### *Dental Treatment in H.M. Prisons.*

Mr. PETHICK LAWRENCE asked the Secretary of State for the Home Department whether his attention had been called to the fact that persons in His Majesty's prisons could not obtain dental treatment other than extractions unless they were prepared to pay for it themselves; and whether, in view of the hardships thereby caused to poor prisoners, he would consider amending the regulations in this respect.—Sir WILLIAM JOYNSON-HICKS replied: No, Sir. In any case of acute pain necessary treatment is given; apart from that dental treatment, other than extraction, can only be given to a prisoner at the public expense if the medical officer considers that his health will be impaired by his waiting for treatment till his sentence has expired. The funds at the disposal of the Prison Commissioners will not permit of more being done in the prisons. At the Borstal institutions regular dental treatment is provided for all the inmates.

## FRIDAY, MAY 14TH.

### *Use of Ultra-violet Rays by Unqualified Persons.*

Colonel DAY asked the Minister of Health if his attention had been drawn to the increasing use of the ultra-violet ray by masseurs, barbers, and other unqualified persons; and, in view of the danger produced by over-dosage in certain cases, he would consider action with a view to the registration of all persons who utilise this method of treatment.—Mr. NEVILLE CHAMBERLAIN replied: I have not received any evidence of injury resulting from the use of ultra-violet rays by unqualified persons, but if the hon. Member is aware of any specific cases in which such injury has arisen, I should be glad if he would furnish me with particulars with a view to further inquiry.

## TUESDAY, MAY 18TH.

### NECESSITOUS AREAS AND PUBLIC HEALTH.

The House went into Committee on the Ministry of Health Vote, Mr. JAMES HOPE, chairman of committees, in the chair. The discussion was resumed on the Government's refusal of a grant from the Exchequer to relieve the financial burdens thrown upon local areas owing to the abnormal state of unemployment.

Dr. HADEN GUEST said that this problem of the necessitous areas was not really a problem at all, but a disease; it was part of the characteristic disease of society—the division between the haves and the have nots. Two things could be done in regard to it. One was attempts at immediate amelioration by means of subsidies of different kinds. But subsidies did not help the fundamental difficulty at all—namely, how to prevent the process of degeneration increasing and how to secure a return to the processes of health. The idea of labour colonies was on the right lines, but it did not cover the whole field. The real trouble was that the people in these poor and necessitous areas were employed in industries which were parasitic on the people engaged in them, and they in turn were parasitic on the community. These parasitic industries paid very low wages, and did not adequately provide for the employment of the people. They made profits and declared dividends because they were really subsidised out of public funds. The conditions of degeneration, both moral and physical, in these areas acted as centres of infection for the whole of the community. They were points in our social life through which the life of the community was being drained away. They ought to separate the sick from the well in this matter just as they did in the case of ordinary disease. They must separate the unemployed and healthy man from the unemployed man who was unhealthy. They should attempt to take out from these areas as large a number of healthy men as possible and set them to work on the land, either in this country or the dominions. Legislation was not required to deal with these questions as the Ministry of Health had large powers which they could exercise administratively for dealing with housing, public health, the treatment of defectives, the treatment of consumptives, and the treatment of other classes of the community who required to be segregated. They could solve the problem of the necessitous areas if they were willing to take a sufficiently big view.

After further discussion,

Mr. NEVILLE CHAMBERLAIN (Minister of Health) said he could only repeat what he had said on the last occasion when this matter was discussed. A number of schemes for relieving the necessitous areas had been examined by a committee who had reported that not one of the schemes was practicable. This was not a time to come upon the Exchequer for further grants. Moreover, if they were to have a central fund distributed for this purpose, there must be central control, and that was what he wished to avoid and thought that he could avoid.

Progress was reported.

---

THE LATE DR. R. WILKINS.—Dr. Richard Wilkins, of Preston, was the eldest son of Mr. T. R. Wilkins, of Longton, and was educated at the University of Edinburgh, where he graduated in medicine in 1905. He became house surgeon at St. Mary's Hospitals for Women and Children in Manchester and resident medical and surgical officer of the Preston Royal Infirmary. In 1909 he left the hospital and settled in practice at Preston, taking his F.R.C.S. at Edinburgh in the following year. At the Preston Royal Infirmary he was honorary assistant surgeon and he acted as secretary of the local Medico-Ethical Society; during the war he saw service as surgeon-lieutenant in the Navy. The high esteem in which Dr. Wilkins was held by the medical profession and people of Preston was shown at his funeral on April 27th. He was only 43 years of age and leaves a widow and one son.

MEDICAL CONGRESS AT BRUSSELS.—The seventh session of the Journées Médicales de Bruxelles will be held from June 26th to 30th under the patronage of the King and Queen of the Belgians. The programme is to include many subjects of topical interest covering the whole range of medicine, surgery, and gynæcology. During the mornings there will be practical demonstrations in hospitals and clinics. Those attending the Congress will be invited to a reception at the royal castle of Laeken. H.R.H. the Duke of Brabant will preside over a banquet in honour of Marshal Lyautey on June 26th, and there will be a gala performance at the opera. An international exhibition of the arts and sciences applied to medicine will be held during the Congress. The Journées Médicales is organised by the *Bruxelles-Médical*, and information may be had from the secretary-general, Dr. R. Beckers, 62, rue du Froissant, Brussels.

# Medical News.

UNIVERSITY OF LONDON.—At a recent examination the following candidates were successful:—

*Diploma in Psychological Medicine* (with special knowledge of Psychiatry).—Donald Cameron, Edward Emerson, Clement Perera, James Skottowe, and Robert Thompson.

*University of London University College Hospital Medical School.*—Mr. Richard Lake will give three Geoffrey E. Duveen lectures in otology at 5 P.M. on Thursdays in June. The subjects will be Deafness and Occupations (June 3rd) and Middle Ear Disease (June 10th and 17th), and the lectures will be open to medical practitioners and students.

A course of four lectures on the Constituents and Coagulation of Blood Plasma will be given by Dr. J. W. Pickering at King's College, London, on Tuesdays, May 25th, June 1st, 8th, and 15th, at 4.30 P.M. Admission will be free without ticket.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—An ordinary quarterly Comitia of the College was held on April 29th, Sir John Rose Bradford, the President, being in the chair. The following were elected to the Fellowship on the nomination of the Council:—

Donald Rose Paterson, George Eric Campbell Pritchard, Sir Henry John Forbes Simson, Wilfred Edgecombe, Harold Pritchard, Frederick George Thomson, William Johnson, Charles Wilfred Vining, Richard Robins Armstrong, John Josias Conybeare, John Cuthbert Matthews, Julian Lionel Priston, John Alexander Drake, Francis Richard Fraser, Ambrose Thomas Stanton, Sir George Seaton Buchanan.

Nominated by the Council under By-law XL (*b*) and proposed to the College for election to the Fellowship: Arthur Edwin Boycott and John Thomson.

The Registrar moved, for the first time, the following temporary by-law in the event of the election of Dr. Stanton: "That Ambrose Thomas Stanton, being resident in Malaya, be *admitted to the Fellowship in absentia*, any by-law to the contrary notwithstanding."

The following candidates having satisfied the Censors' Board were proposed for election as Members:—

William L. Ackerman, Harold C. Beccle, Frank B. Byrom, Alexander M. Cooke, William E. Cooke, William S. C. Copeman, Edward R. Cullinan, Arthur J. Davies, Cyril F. Fernando, William Fletcher, Henry Fraser, Clifford J. Fuller, Birendra Nath Haira, Hubert W. Hetherington, Grosvenor C. Millis, Maurice Newman, Alan B. S. Owen, Sydney W. Patterson, Harry V. Phelon, Kenneth Playfair, Thomas W. Preston, Thomas A. Ross, Eric B. Strauss, Horace F. Turney, Gladys M. Wauchope, Joseph Whitby, John F. Williams.

An announcement was made that Mr. Dighton Pollock had accepted the office of Junior Standing Counsel and Dr. S. W. Wheaton that of delegate to the Jubilee Conference of the Royal Sanitary Institute in London in July, 1926.—It was reported that the late President, acting on behalf of the College, had expressed the willingness of the College to bestow a Fellowship, scholarship, or prize out of the income of some £8000 to be left as a legacy to the College for research work in Disorders of Metabolism, but with a preference for the study *of their occurrence* in children and adolescents, and particularly for diabetes.—Dr. H. Morley Fletcher was elected Senior Censor.—The President was appointed to represent the College at the celebration of the bicentenary of the Faculty of Medicine of the University of Edinburgh on June 10th and 11th next.—It was left to the President to appoint a Fellow to represent the College at the Twelfth Annual Conference of the National Association for the Prevention of Tuberculosis at Glasgow on July 1st, 2nd, and 3rd next.—Sir Humphry Rolleston was elected a member of the Executive Committee of the Cancer Research Fund.—A letter was received from the Royal Institute of Public Health asking the College to appoint delegates to their congress to be held in the city of Bristol from May 19th to 24th.—Sir Douglas Powell, Bart., offered to the College a replica of a portrait of his father, the late Sir Richard Douglas Powell, Bart., painted some 30 years ago by Spencer Watson, A.R.A., the replica to be painted by the same artist. This offer was accepted and the thanks of the College accorded to Sir Douglas Powell.—Reports were received from the Committee of Management.—The Registrar gave notice that at a forthcoming *general meeting* of the College he will propose, on behalf of the Censors' Board, additional regulations for the Membership Examination as follows:—

Every candidate for the membership shall furnish proof:

(1) That he has been engaged in work in a clinical laboratory for a period of at least three months subsequent to qualification, and that he has received instruction in modern methods of clinical pathology.

(2) That he has held a house physicianship at a hospital approved by the Censors' Board for a period of at least six months, or some other appointment involving personal responsibility for patients, which shall be considered by the censors as equivalent.

A proposal that the tenure of the office of President should be limited to three years was defeated after some discussion.—Some formal College business was transacted and the President then dissolved the Comitia.

A meeting of the Comitia was held on May 13th, the President, Sir John Rose Bradford, being in the chair.—The following, having been elected to the Fellowship at the meeting on April 29th, were admitted as Fellows:—

Sir Henry John Forbes Simson, Wilfred Edgecombe, Harold Pritchard, Frederick George Thomson, William Johnson, Charles Wilfred Vining, Richard Robins Armstrong, John Josias Conybeare, John Cuthbert Matthews, Julian Lionel Priston, John Alexander Drake, Francis Richard Fraser.

Under By-law XL (*b*).—Arthur Edwin Boycott, John Thomson.

It was resolved that Ambrose Thomas Stanton be admitted to the Fellowship in absentia.—Two Licences were granted.—Prof. Arthur J. Hall was appointed the representative of the College at the forthcoming celebration of the coming of age of the University of Sheffield.

The following additional by-law, having been moved for the second time by the Registrar, was passed:—

"If the Committee of Management of the Conjoint Examining Board or the Examiners shall find any circumstances in the character, conduct, or mode of practice of any candidate for examination which, in the opinion of a majority of either of them, renders such a candidate unfit to become a Licentiate of the College, they shall have power to decline to examine him or to continue his examination, until the decision of the College shall have been given on a report of the circumstances submitted to them by the Committee of Management or the Examiners."

The President then dissolved the Comitia.

The next examination for the Charles Murchison Scholarship in Clinical Medicine will be held on Monday, June 28th, and the days following. Candidates must send in their names to the Registrar not later than June 12th.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—Following the final examinations of the Conjoint Board held from April 6th to 20th licences to practise were conferred upon 165 men and 20 women who have passed the Final Examination in medicine, surgery, and midwifery, and have complied with the by-laws of the Colleges. The following are the names and medical schools of the successful candidates:—

M. O. Abdeen, Birmingham; C. E. Allen, Guy's; Marion L. Bainbridge, Manchester; J. C. H. Baird, St. Bart.'s; M. Barer, Univ. Coll.; R. E. Barrett, London; C. H. Bellerby, St. Bart.'s; P. G. Bentliff, Cambridge and Middlesex; C. E. Bigger, Cambridge and St. Thomas's; C. R. Birnie, King's Coll.; L. R. H. Birt, Guy's; A. D. Blackwell, Middlesex; B. Blaxill, Cambridge and St. Thomas's; J. L. Blonstein, Univ. Coll.; W. R. Blunt, St. Thomas's; J. D. Borham, Cambridge and Middlesex; Kathleen M. Bowman Manifold, Royal Free; D. G. Down, Guy's; G. J. O. Bridgeman, Cambridge and St. George's; G. H. Brown, Cambridge and Liverpool; H. Bruce, Leeds; P. H. Buckton, Cambridge and King's Coll.; H. A. Bulman, Middlesex; F. Bumjé, St. Mary's; A. Burlingham, Univ. Coll.; C. H. Burridge, St. Thomas's; H. A. Byworth, Oxford and St. George's; E. Carew-Shaw, St. George's; Elizabeth J. *Carpenter*, Royal Free; A. G. Chamberlain, St. Bart.'s; G. P. Chandler, Cambridge and St. Thomas's; J. C. K. Chilcott, King's Coll.; Enid Clarke, Royal Free; S. M. Coleman, St. Bart.'s; A. B. Connell, Cambridge and St. Thomas's; R. A. P. Corkery and J. G. Cox, St. Bart.'s; Lucy M. Cranage, Royal Free; G. H. Crisp, Oxford and St. Bart.'s; C. R. Croft, Oxford and St. Thomas's; B. R. Crossley, Univ. Coll.; Olive C. Crowley, Charing Cross; P. C. Cumber, Guy's; P. C. Datta, Calcutta; *T. L. Davies*, Oxford and London; J. E. Debono, Malta; J. H. de Jager, Cape and Guy's; T. S. Dewey, Cambridge and St. Thomas's; D. A. Dewhirst, St. Bart.'s; A. F. Downie, Birmingham; I. A. Dubinsky, Halle; R. A. M. Dyke, Guy's and Glasgow; W. G. I. Dyson, Manchester; R. P. S. Eddon, St. Mary's; A. G. Eddison, Cambridge and Univ. Coll.; G. Edwards, St. George's; G. C. Edwards, St. Thomas's; M. N. El Din, St. Bart.'s; E. Evans, Sheffield; E. S. Evans, Cambridge and St. Thomas's; J. P. *Evans*, Charing Cross; J. A. Eyres and A. B. Field, King's Coll.; R. A. FitzSimons, Charing Cross; R. G. Flower, Leeds; J. N. C. Ford, Oxford and St. Bart.'s; R. M. Forsyth, London; E. L. Fothergill, Oxford and St. Thomas's; A. R. French, London; J. Freudenheim, Charing Cross; Margaret L. A. Galbraith, Birmingham; W. L. Gilbard, St. Bart.'s; R. S. Glennie, St. Thomas's; L. D. Golomb, Odessa and Middlesex; J. Gray, Cambridge and Guy's; R. M. Greenop, *King's Coll.*; E. J. *Greenwood*, Cambridge and Guy's; T. W. Griffiths, Middlesex; H. L. Groom, Univ. Coll.; G. J. Gross, Cambridge and King's Coll.; K. H. A. Gross, Cambridge and St. George's; B. Guyster, London; A. F. W. Hall, Guy's; H. J. Heathcote, Cambridge and St. Bart.'s; T. H. Hobbes, St. Bart.'s; A. Hobson, Birmingham; L. E. Houghton, Cambridge and Guy's; J. L. Howard, Bombay and St. Mary's; L. G. Howe, St. Thomas's; M. L. Hutchinson, Guy's; D. Imber, Cape and St. Bart.'s; F. T. *Ioulanitoff*, St. Bart.'s; J. H. F. Jayasuriya, Ceylon and Middlesex; Iris A. J. Lloyd, Royal Free; D. M. Johnson, Cambridge and St. Bart.'s; R. G. Johnston, Adelaide and London; A. W. Kendall and

J. W. Kendall, King's Coll.; Eileen M. King, Univ. Coll.; S. N. Lahiri, Calcutta and Dundee; Alice B. Laker, Punjab and Charing Cross; J. R. E. Lee, Cape and Liverpool; H. P. Lehmann, St. Bart.'s; H. L. Lollo, Univ. Coll.; D. H. Lewis, St. Mary's; P. C. K. Lewis, Birmingham; L. Lipschitz, Berlin and Middlesex; G. H. Livingstone, King's Coll.; Elsie Lyon and Margaret B. Macdonald, Charing Cross; Mary A. C. MacHugh, King's Coll.; R. M. Maher, Liverpool; A. R. Marsh and C. W. Marshall, Guy's; Florence I. J. Masterman, Royal Free; A. N. Mathias, St. Mary's; C. A. L. Meredith, Middlesex; J. H. Miller, Birmingham; H. L. Milles, Cambridge and King's Coll.; J. M. Milloy, Glasgow and London; D. E. J. Mitchell, Manchester; E. D. Moir, Cambridge and St. Bart.'s; J. W. Monro, Cambridge and London; E. W. Morgan and J. E. C. Morton, St. Bart.'s; C. E. H. Moykopf, Guy's; M. Murad, Cairo and Birmingham; B. L. S. Murtagh, Birmingham; A. H. Musgrove, Cardiff and Guy's; H. P. Nelson, Cambridge and St. Bart.'s; C. S. Netscher, Bombay and St. Mary's; D. A. Newbery, Guy's; R. Okell, Oxford and St. Bart.'s; E. R. S. Owen, Liverpool; Evelyn M. Pakeman, Royal Free; Marion G. Palmer, Univ. Coll.; S. C. St. G. C. Parry, Cambridge and Middlesex; W. E. Parry, London; A. Patrick, Edinburgh; P. H. Perkins, London; E. K. Pritchard, St. Thomas's; Henrietta Procter, Charing Cross; M. M. Raouf, Cairo and St. Thomas's; W. H. G. Reed, Cambridge and King's Coll.; J. H. Ripka, London; M. E. D. Roberts, Cambridge and Birmingham; R. I. Roberts, Manchester; Janet McL. Robertson, St. Mary's; E. Robinson, Guy's; Alice L. Robson, Royal Free; E. H. Roche, Guy's; Sibyl D. Rodgers, King's Coll.; F. C. Roles, Cambridge and St. Bart.'s; R. P. Ross, Cambridge and King's Coll.; H. W. Sadler, Cambridge and St. George's; J. de la M. Savage, Oxford and St. Bart.'s; J. W. Schofield, Middlesex; J. W. Schollum, Guy's; J. A. Screech and S. T. Seccombe, St. Thomas's; M. Sendak, St. Mary's; Nancie A. Simmons, Charing Cross; J. F. Simpson, St. Mary's; W. E. Snell, Cambridge and Univ. Coll.; A. W. E. Soysa, King's Coll.; Beryl M. Stevens, St. Mary's; Dorothy E. Stewart, Royal Free; E. C. N. Strong, Birmingham; M. M. Su, Calcutta and Leeds; T. H. Taylor, Leeds; S. E. Theis, Guy's; J. W. de W. G. Thornton, Oxford and King's Coll.; G. P. Thorold, Oxford and St. Thomas's; O. R. Tisdall, Oxford and St. Bart.'s; E. M. Town-Jones, Cambridge and Leeds; Mary M. Tulloch, Charing Cross; W. J. D. Twort, Univ. Coll.; C. C. Ungley, Durham; E. F. C. Wadge, King's Coll.; H. Walden, Leeds; F. H. A. Walker, Cambridge and St. Bart.'s; E. Walsh, Manchester; Betty C. Waters, St. Mary's; T. E. Watkins, Cardiff; J. G. Wigley, Cambridge and St. Thomas's; J. I. Williams, Middlesex; H. Winch, St. Bart.'s; Eileen C. Wise, King's Coll.; W. R. Wood, Oxford and St. Thomas's; Rosa S. Wordsworth, Oxford and Charing Cross; H. P. Yew, Guy's; H. R. Youngman, Cambridge and St. Thomas's; and A. B. Zimbler, Dorpat and Middlesex.

The following candidates were approved in the subjects indicated, but are not eligible for diplomas:—

*Medicine.*—C. E. H. Anson, King's Coll.; Cecile H. D. Asher, Royal Free; M. I. Ashmawi, Cairo and St. Thomas's; B. Barling, Univ. Coll.; J. T. Barr and Grace Batten, King's Coll.; W. Blood, London; Susanna M. Bornman, Royal Free; J. W. Bottoms, London; R. D. W. Butler, Birmingham; S. Carnofsky, Guy's; Muriel G. E. Clark, Charing Cross; A. P. L. Cogswell, King's Coll.; W. K. Coombes, St. Mary's; E. Corner, London; H. A. H. D'Silva, King's Coll.; H. G. de Silva, Ceylon and Middlesex; C. W. L. de Souza, St. Bart.'s; Irene Dixon, Charing Cross; Leonora S. Evans, Royal Free; R. Evans, Guy's; G. L. Feneley, Bristol; C. Fernando, Ceylon; E. G. Frewer, London; Dorothy Gibbs, Charing Cross; B. W. Goldstone, St. Mary's; W. P. Greenwood and T. L. Griffiths, St. Bart.'s; Linnie A. Hamar, Charing Cross; P. E. T. Hancock, Cambridge and St. Bart.'s; W. V. Harke, St. Thomas's; S. T. Harris, Charing Cross; G. G. Hill, London; A. S. Hollins, King's Coll.; Nancy G. Howell, Univ. Coll.; T. C. Hunt, St. Mary's; M. K. Hussein, Cairo and St. Bart.'s; Mary R. Isaac, Madras and Royal Free; R. W. Kenney, London; W. A. Kerr and Isabella L. H. Livingstone, King's Coll.; D. G. Lloyd, London; Joyce McConnell, Royal Free; C. W. Mackenzie, London; J. H. Marshall, Birmingham; Mary S. Mitchell, St. Mary's; Anna P. Montgomery, Charing Cross; L. Moss, London; B. G. S. Mudali, Madras; Sybille L. Myers, Dorothy L. Neate, and Marjorie E. Parfitt, Royal Free; F. Parker, G. F. D. Perrott, and M. M. Posel, St. Bart.'s; H. J. Powell, St. Mary's; W. H. D. Priest, King's Coll.; Muriel F. Prout, Royal Free; E. J. Pye-Smith, Cambridge and Guy's; R. H. Rattray, Edinburgh; Hilda M. Richards, Royal Free; Margaret A. Ritchie, Charing Cross; D. A. Robertson, London; R. Roderick, St. Bart.'s; T. W. M. Ross, London; G. P. Roxburgh, St. Bart.'s; W. Samarasinghe, Middlesex; R. W. A. Simmons, St. Thomas's; B. A. Smith, King's Coll.; G. H. A. Soysa, Ceylon; J. R. C. Spicer, Guy's; J. B. Stauffer, London; M. M. Suzman, Durham; L. H. Thomas, St. Thomas's; A. C. Welch, Leeds; D. F. Whitaker, Univ. Coll.; E. G. Williams, Leeds; A. A. Wilson, St. Mary's; C. S. Wise, St. Bart.'s; and H. L. C. Wood, King's Coll.

*Surgery.*—G. E. Aling and J. H. Anderson, Guy's; J. M. Ashton, St. Thomas's; M. T. Aung, Guy's; L. G. Backhurst, St. Thomas's; P. Berry, Guy's; J. A. F. Bouloux, Univ. Coll.; M. D. Bower, St. Thomas's; H. Bown, Sheffield; R. C. Brock, Guy's; H. J. Burrows, St. Bart.'s; E. S. Caley, St. Thomas's; G. D. G. Cameron, Leeds; P. J. L. Capon and J. C. D. Carothers, St. Thomas's; F. H. Chick, Birmingham; Evangeline A. Clark, Royal Free; A. Cohen, London; Constance M. Corbett, Westminster; F. H. N. Cruchley, London; A. T. Curnow, Guy's; C. A. Day, St. Bart.'s; H. A. H. D'Silva, King's Coll.; J. H. A. Donnelland, St. Bart.'s; J. Dywien, Guy's; J. A. Edwards, St. Bart.'s; A. P. Farmer, St. Thomas's; A. W. Fawcett, Edinburgh; A. E. Fraser-Smith, St. Bart.'s; L. W. Freeman, St. Mary's; E. G. Frewer, London; J. F. Galloway, Liverpool; J. B. George, St. Thomas's; J. A. Gornall, Manchester; E. C. Grant, St. Mary's; E. D. Y. Grasby, Guy's; L. C. Gunasekara, King's Coll.; C. H. Harper and G. R. N. Henry, St. Thomas's; V. V. H. Hoskai, Guy's; M. F. Hope, King's Coll.; H. O. Hopkins, Middlesex; W. H. Hudson, St. Bart.'s; Isabelle R. Humphreys-Owen, King's Coll.; W. T. Hunt, St. Mary's; Roberta I. Hutchinson, Birmingham; B. S. Jarvis, Liverpool; A. J. Johnson, St. Bart.'s; E. C. Johnson, St. Mary's; A. N. Jones, Liverpool; W. T. Jones, Cardiff; B. Kaplan, Guy's; D. T. Lewis, Middlesex; H. W. Lewis-Philipps, Guy's; D. A. Llewelyn, St. Bart.'s; M. N. Menon, Guy's; Bertha I. Meyer, Royal Free; A. D. Miller and H. W. Morok, Durham; E. J. Newman, London; E. F. D. Owen, St. Bart.'s; D. Perkoff, London; C. L. Potts, Birmingham; E. I. Puddy, St. Mary's; Hilda H. Reeves, Birmingham; J. H. O. Roberts, St. Bart.'s; D. A. Robertson, London; J. A. Rushworth, Manchester; B. F. Russell, London; N. A. Saif and A. E. Y. M. Salama, St. Thomas's; H. N. Seymour-Isaacs, St. Bart.'s; H. L. Shimmin, Manchester; V. C. Shroff, Westminster; A. Signalowsky, Guy's; R. W. A. Simmons, St. Thomas's; J. W. Simpson, Manchester; B. D. Sindhwani, Durham; E. W. Skipper, London; Peggie P. Slater, Westminster; S. Smith, St. Bart.'s; J. B. Stauffer, London; W. Summers, Birmingham; M. M. Suzman, Durham; Mary Thomas, Univ. Coll.; S. R. Trick, Guy's; O. L. Truscott, D. P. Wailling, and A. S. Wallis, St. Thomas's; A. C. R. Walton, Birmingham; R. F. Ward, London; D. A. J. Williams and G. P. Williams, Cardiff; L. S. Williams, Guy's; and J. Woolf, St. Thomas's.

*Midwifery.*—Edna E. Adams, Birmingham; G. E. Aling, Guy's; A. M. Anderson, Edinburgh; V. F. Anderson, Westminster; C. E. H. Anson, King's Coll.; Laura G. Apps, London; H. C. Aslett, St. Mary's; B. Barling, Univ. Coll.; J. T. Barr, King's Coll.; Florence I. Beech, Birmingham; H. O. Blauvelt, Univ. Coll.; J. F. O. Bodman, Bristol and St. Mary's; E. J. Boschi, Leeds; J. A. F. Bouloux, Univ. Coll.; H. W. Bowen and M. D. Bower, St. Thomas's; R. C. Brook and S. B. Browning, Guy's; G. D. G. Cameron, Leeds; J. C. D. Carothers, St. Thomas's; C. N. Chandrachud, Bombay; J. A. Cholmeley, St. Bart.'s; E. T. Clifton, Guy's; A. P. L. Cogswell, King's Coll.; A. Cohen, London; Annie A. Corp, Royal Free; C. E. Corrigan, Manitoba; C. B. Crofts, St. Mary's; E. S. Curtiss, W. W. Darley, and T. G. Davies, St. Bart.'s; O. Dawood, Liverpool; C. A. Day, St. Bart.'s; Irene Dixon, Charing Cross; J. H. A. Donnelland, St. Bart.'s; M. H. O. Dyson, Univ. Coll.; A. S. El-Katib, St. Thomas's; H. M. Elliott, St. Bart.'s; J. P. Evans, Guy's; Leonora S. Evans, Royal Free; A. P. Farmer, St. Thomas's; A. W. Fawcett, Edinburgh; G. L. Feneley, Bristol; R. F. Fidler, Middlesex; Dorothy D. Forster, St. Mary's; G. W. S. Foster, St. Bart.'s; H. S. Gaussen, Guy's; J. B. George, St. Thomas's; Dorothy Gibbs, Charing Cross; R. M. Gilchrist, St. Bart.'s; E. D. Y. Grasby, Guy's; Rosaleen L. Graves, Charing Cross; C. H. Harper, St. Thomas's; S. T. Harris, Charing Cross; J. C. Hawkesley, Univ. Coll.; C. Hooper, London; E. E. R. Hopkin-James, Cardiff; Nancy G. Howell, Univ. Coll.; Roberta I. Hutchinson, Birmingham; Mary R. Isaac, Madras and Royal Free; Marie E. Jackson, Birmingham; D. Jacobson, St. Bart.'s; S. F. Jayawardene, Ceylon and Univ. Coll.; B. C. Jennings and Louise A. Johnson, Birmingham; L. Karnofsky, St. Thomas's; R. W. Kenney, London; K. D. Kumria, Univ. Coll.; A. H. Lafone, St. Mary's; P. N. Lahiri, Calcutta and Guy's; S. C. H. Lane, Guy's; Greta M. Langdon, Royal Free; C. J. Laviers, St. Bart.'s; Isabella L. H. Livingstone, King's Coll.; L. G. Llewellyn, Middlesex; G. E. Macdonald, London; R. M. B. Mackenna, St. Thomas's; P. C. Mallam, St. Mary's; E. T. Mankabadi, London; J. H. Marshall, Birmingham; Helen E. Mayfield, St. Mary's; Margaret Mitchell, Birmingham; A. W. J. Williams, Guy's; T. P. Williams, St. Bart.'s; and H. L. C. Wood, King's Coll.

HARVEIAN SOCIETY OF LONDON.—The date of the annual dinner of this society has been altered from Thursday, *June 10th, to Thursday, June 17th.*

ROYAL SOCIETY OF MEDICINE.—The society's *house and library will be closed on Saturday,* May 22nd, and Monday, May 24th.

BOLINGBROKE HOSPITAL.—Sir James and Lady Carmichael have announced their intention of presenting to this hospital at Wandsworth Common a *fully-equipped* children's ward of 22 beds and a freehold house to be used as a nurses' home

THE first International Congress of Sexuology will be held at Berlin from Oct 11th to 15th, 1920, under the auspices of the International Society of Sexuology All aspects of the subject will be discussed. Further information may be obtained from Dr Moll, 15, Kurfürstendamm, Berlin W

PEOPLE'S LEAGUE OF HEALTH.—The fifth travelling scholarship prize awarded by the People's League of Health *in connexion with the Sims Woodhead series of educational* health lectures has been won by Mr G R. Watt, assistant master at *Stowey* Open-air School.

BRITISH SOCIAL HYGIENE COUNCIL.—The annual *general meeting will be held at 1* Wimpole-street, London W on June 18th at 3 15 P.M. It is announced that the conference on Congenital Syphilis and the Display of a Medical Film in connexion with the Nation's Health Exhibition at Leicester will now take place on Thursday June 3rd, *instead of* on May 20th as was previously arranged.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The Cavendish lecture on Vision and Evolution will be delivered by Prof G Elliot Smith, F R.S., on Friday, May 28th at *8.30 P.M., at the* Kensington Town Hall and will be followed by the annual conversazione Reception by the President at 8 P.M. Tickets may be *obtained for* members of the medical profession and their friends through members of the society

AT the annual convention of the American Medical Association and its medical exhibition on scientific subjects the gold medal was awarded to Dr Aldo Castellani, who recently delivered the Gehrman memorial lectures at the University of Illinois. The award 'was based on the excellent investigation in comparatively unexplored fields of medicine and for the perfection of the display' of specimens.

ST MARY'S HOSPITAL INSTITUTE OF PATHOLOGY AND RESEARCH.—The remaining lectures of the course on Pathological Research in its Relation to Medicine will be as follows; Prof David Wilkie on the Functions of the Bile Passages in Relation to their Pathology (May 27th); Prof. Joseph Barcroft on Recent Work on *the Spleen (May 31st)*; Dr Charles S. Myers on Freudian Psychology (June 3rd); Dr John Freeman on the Pathological Mechanism of the Asthma Syndrome (June 10th); and Mr J E. Barnard on the Microscopy of Filterable Viruses (June 17th). The lectures are open to all members *of the medical profession* and medical students without fee They are held in the lecture room of the Bacteriological Department at 5 P.M.

HERBERT JONES TESTIMONIAL FUND.—The following is a further list of subscribers to the fund *being raised* as a testimonial to the public services of Dr Herbert Jones, M O H for the Herefordshire combined districts who is retiring *on account of ill health.* A previous list appeared in our issue of May 1st

*£5.*—Dr J C. Thresh.*

*£3 3s.*—Dr R. Veitch Clark.*

*£2 2s.*—Drs. W F Corfield,* R. A Dunn (Hertford) W Foster (Shipley), Lieut.-Colonel F E. Fremantle M.P., Drs. C O Hawthorne (London) W H. Hill (Oxford) A B McMaster,* H Meredith Richards (Whitehall), Sir John Robertson,* C.M.G., O B.E. J Williamson *(Epsom).*

*£1 1s.*—Dr G C Anderson (British Medical Association) Surg Captain C W Andrews,* O.B.E., R.N., Drs. E G Annis,* H W Barnes *(Hereford)* W Benton,* C S. Brebner (Richmond, Surrey), W. D Carruthers,* W F Dearden,* C E. Douglas (Cupar-Fife) L A Drake (Cradley), A Mearns Fraser,* Nicholas Gebbie,* A. Gilmour (Wimbledon), C. R. Gibson (Guisborough) R. Ashleigh Glegg,* W L. M. Those marked with an asterisk per the *Medical Officer*

CHINA MEDICAL ASSOCIATION.—The Eighteenth Biennial Conference of the China Medical Association will be held at Peking from August *31st to Sept. 8th* The executive secretary is Dr James L. Maxwell

MEDICAL GOLFING SOCIETY.—In the *final* of the Spring Tournament, Mr Joseph Cunning defeated Dr E. Ravensworth Hart at the *nineteenth hole, thus winning* the T P Kolesar cup.

RELIGIOUS SERVICES AT ST GEORGE'S HOSPITAL.—That the patients may take part in the religious services, a microphone has been installed in the chapel The patients in the wards listen by means of the ordinary receiver and head phones.

UNIVERSITIES' LIBRARY FOR CENTRAL EUROPE.—The report on the fifth year's work of the Library draws *attention* to a desire in the new countries of Europe for a knowledge of British culture and institutions An appeal is made *for gifts* of books to be *distributed amongst* needy universities and educational bodies abroad. Such gifts it is suggested, have a stabilising effect on international relations for they can only lead to a spirit of toleration and common intellectual advancement. Funds are also needed, and any *contributions may be sent* to the hon. secretary, Mr B M Headicar, at the London School of Economics, Houghton-street, Aldwych London W C. 2

BELFAST HOSPITALS.—Lady Craig, the wife of the *Prime Minister of Northern Ireland,* is trying to raise £25 000 towards the rebuilding of Belfast Samaritan Hospital for Women "The accommodation is hopelessly inadequate the equipment pathetically out of date, and the quarters for the nursing staff deplorably insufficient," *while the medical staff work under the heaviest handicaps.*—Belfast Hospital for Sick Children is to be rebuilt at a cost of £80 000.—At the *annual meeting* of Belfast Ophthalmic Hospital it was stated that *one* patient in every five is operated upon, and that the old Irish prejudice against sending children to the hospital is passing away

EPSOM COLLEGE.—The seventy-third annual general meeting of the Governors of Epsom College will be held on Friday, June 25th, at 49, Bedford-square, London, W C The *health* of the school during the year under review has been satisfactory, except for minor epidemics of chicken pox and mumps in the *Michaelmas* term. The general social life has maintained a high standard, and all sports—cricket, football gymnastics fencing, boxing, and fives—*have been* keenly followed. Since the last annual general meeting E. L. Clarke has been awarded the Senior Open History *Scholarship of £80* per annum at Clare College Cambridge; 13 boys entered for the First Examination for Medical Degrees as follows: London, 11 candidates, of whom six were successful and five were partially successful; Cambridge, three candidates, of whom two were successful in all four parts, and one was successful in one part Eleven candidates presented themselves for the London University Higher School *Examination, of* whom four were successful two were successful in three parts, two in two parts, and one in one part. Five candidates entered for the *Intermediate* B.Sc Examination through Higher Certificates, of whom four were successful. Of 72 boys who presented themselves for the *London University* General School Examination 60 gained school certificates, including four with honours 42 of whom gained exemption from *matriculation.* The distinctions gained in individual subjects numbered 51. One boy was successful at the Conjoint Board Pre-Medical Examination, and 25 boys obtained the War Office Certificate 'A.' Last year the Armstrong Scholarship was awarded to H. V A. Franklin the Da Silva *Exhibition* to C. L. Heanley, the Stone Scholarship to D S. Clogg, and the Jenks Memorial Scholarship to C Ive The St. Bartholomew's Hospital Scholarship was awarded to W D Coltart the St. Mary's Hospital Scholarship to J S Cotman the University College Hospital *Scholarship, together* with the Carr Exhibition which goes with it, to J C. S. Wells, the Middlesex Hospital Scholarship to R. G G Evans, and the *London Hospital* Scholarship to D C McClure Those wishing to send their sons to the College should give immediate notice to the head master *in order* that their names may be entered on the waiting list which is now unusually long and is steadily increasing

*New Benefactions.*—The Council of the College reports the establishment of two new benefactions. The late Dr James Taylor left the sum of £1000 to establish a scholarship in memory of the late Rev W A. Thomas, for many years a master at the College This scholarship will be devoted to the furtherance of the education of any specially meritorious boy whilst still a pupil at the College, in any way that the Council acting on the advice of the head *master* may consider desirable The late Miss Mary Elizabeth Dunn left by her will a sum of £850 New Zealand 4 per cent. Inscribed Stock to institute a "Robert Dunn" Annuity of £32 a year for the oldest unsuccessful unmarried candidate at the last election of a 'Morgan' Annuitant

THE Homœopathic Hospital, London, is closing for three months from June 1st to Sept. 1st for extension. It will be open until May 29th for treatment.

THE Oldham Health Committee has accepted an anonymous donor's offer of a building and equipment for orthopædic and sunshine treatment costing about £4000.

TOUR OF ITALIAN HEALTH RESORTS.—The annual medical tour of Italian health resorts will be held from Sept. 12th to 28th. Among the places to be visited are Abbazia, Grado, the Lido, Abano, Roncegno, Levico, Merano, Riva, Gardone, and Salsomaggiore. The number of participants is limited to 200. A limited number of places are reserved for relatives of doctors making the tour. Further particulars may be had from the Tourist Office of Italian State Railways, 12, Waterloo-place, London, S.W. 1.

STUDENT RIVALRIES IN "RAG" COLLECTIONS.—Students of the University of Glasgow and of the extra-mural colleges have issued a challenge to English universities regarding the collection of money for charities on "rag day." The Glasgow students on Jan. 16th collected £10,000 for local charities, and according to the University magazine it has come to their knowledge that Manchester students claim to have beaten the Glasgow record by £500. After consideration the Glasgow students have decided to challenge certain English universities and university colleges to raise next session by their gala day or week a sum which will exceed that collected by Glasgow. The challenge is not directed against any of the Scottish universities. Certain conditions are laid down, one being that all money collected shall be money which, but for the students' efforts, would not have found its way to charity.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—At the annual general meeting of the Fund, over which the Prince of Wales presided at St. James's Palace on May 14th, Lord Burnham, as chairman of the Propaganda Committee, said that though the net income of the Fund was not large, its indirect results were prodigious. He stated that a cheque had been received in appreciation of the work of the British Broadcasting Company during the strike. The meeting decided to offer assistance from the King's Fund towards providing pensions for hospital officers and nurses; a maximum sum for seven years of £20,000 a year, or 25 per cent. of the expenditure of the hospitals on the approved scheme, whichever is the smaller; this amount is to be provided as far as possible by means of contributions obtained by a special appeal in selected quarters, the contribution to be increased if sufficient funds are realised by such appeal. The Prince of Wales said that he was glad to hear from the treasurer, Lord Revelstoke, that the record distribution of £245,000 was met out of the year's income, and that there was probably enough margin to maintain that total undiminished in future years if a fair amount was received from legacies. Although the hospitals had suffered financially from recent events, His Royal Highness trusted that there would be a general determination to see that the loss should be only temporary. He read a message from the King in which His Majesty expressed his great satisfaction with the past year's working of the Fund, a result which he hoped would be repeated in 1926.

WIDOWS', ORPHANS', AND OLD AGE CONTRIBUTORY PENSIONS ACT.—The Minister of Health has issued a statement drawing attention to the conditions on which old age pensions may be granted under the Contributory Pensions Act, 1925. The position is that from July 2nd, 1926, old age pensions at the full rate of 10s. a week will be payable without any inquiries about means or nationality to men and women who are then at least 70 years of age and have been continuously insured under the National Health Insurance Acts from April 29th, 1925, to the date of their seventieth birthday. Persons who become 70 between July 2nd, 1926, and Jan. 2nd, 1928, and who have been insured from April 29th, 1925, until the age of 70 will be entitled to pensions at the full rate of 10s. a week on attaining the age of 70. The person must, however, have been resident in Great Britain or Northern Ireland for the two years immediately before the date on which the pension would become payable, and his (or her) last employment (except temporary employment) must have been in Great Britain or Northern Ireland. The wife of an insured man who is himself entitled to a pension is also entitled to a pension of 10s. a week in right of her husband's insurance if she is at least 70 years of age, or on reaching that age after July 2nd, 1926; but if the marriage took place after April 29th, 1925, a pension will not be payable to the wife in right of the husband's insurance until five years after the marriage, unless she was in receipt of a widow's pension immediately before marriage. A woman who obtains an old age pension in right of her own insurance cannot also claim a pension in respect of her husband's insurance. A leaflet explaining the position in greater detail can be obtained at any post office.

THE Summer Session of the General Medical Council will open on Tuesday, June 1st, when Sir Donald MacAlister, the President, will take the chair at 2 P.M. and give an address.

DR. F. J. BROWNE, lecturer in clinical obstetrics at the University of Edinburgh, has been appointed, as from July 1st next, to the London University chair of Obstetric Medicine, tenable at University College Hospital Medical School.

LEICESTER ROYAL INFIRMARY.—The reconstructed X ray department was opened on April 22nd by the Mayoress of Leicester. Dr. A. E. Barclay, of Manchester Infirmary, delivered an address for which Mr. Cecil Marriott and Mr. W. J. Cumberlidge proposed a vote of thanks. The cost of the new department is about £6500.

MEDICAL STUDENTS AT DROITWICH.—A party of some 30 medical students from Birmingham University, under the guidance of Dr. Douglas Stanley, visited Droitwich on May 15th, and were conducted over the brine baths by local members of the medical profession, the methods of treatment being fully explained to them.

CHELSEA CLINICAL SOCIETY.—A meeting of this society was held on April 20th. In the absence of the President, Dr. Gordon Lane occupied the chair, and a discussion on the Treatment of Late Syphilis was initiated by Prof. John Eyre and continued by Dr. C. E. Sundell. It was generally agreed that the injection of salvarsan or its allies was of great benefit in the amelioration of symptoms of general paralysis and locomotor ataxy, and that in some cases it effected an apparent cure. One or two speakers laid stress on the importance of treating syphilitic women during pregnancy, even though they might show no signs of the disease. The importance of bismuth preparations was urged by more than one speaker, who rated its value in the treatment of late syphilis as at any rate equal to that of mercury and potassium iodide.

ROCKEFELLER MEDICAL FELLOWSHIPS.—Rockefeller Fellowships for the academic year 1926–27 will shortly be awarded by the Medical Research Council, and applications should be made not later than June 10th, 1926. The Fellowships are provided from a fund which the Rockefeller Foundation has entrusted to the Medical Research Council. They are awarded by the Council to graduates who have had some training in research work in the primary sciences of medicine, or in clinical medicine or surgery, and are likely to profit by a period of work at a university or other chosen centre in the United States before taking up positions for higher teaching or research in the British Isles. A Fellowship will have the value of not less than £350 a year for a single Fellow, with extra allowance for a married Fellow, payable monthly in advance. Travelling expenses and some other allowances will be made in addition. Full particulars and forms of application are obtainable from the Secretary, Medical Research Council, 15, York Buildings, Adelphi, London, W.C. 2.

ROCKEFELLER GIFTS.—The Rockefeller Foundation has given £15,000 to St. Thomas's Hospital, London, towards the building of new laboratories. It is announced that Mr. John D. Rockefeller has given £35,000 to the medical faculty of the University of Strasbourg.

KING —On May 12th, at The Knoll, Horsham, Thomas William King, M.D, aged 84

REID —On May 14th Alexander Reid M.D, aged 82

WILSON —On May 13th, at Abbey Mount, Torquay, Lindsay W Wilson L.D S R.C.S, in his 33rd year

*N.B —A fee of 7s. 6d. is charged for the Insertion of Notices of Births Marriages and Deaths.*

# Notes, Comments, and Abstracts.

## THE SMOKING HABIT AND MENTAL EFFICIENCY.

### AN INQUIRY INTO THE ASSOCIATION BETWEEN SMOKING AND SCHOLARSHIP.

By J. Rosslyn Earp, M.A. Camb., M.R.C.S. Eng.,
ANTIOCH COLLEGE, YELLOW SPRINGS, OHIO, U.S.A.

This inquiry is concerned not with the immediate effects of smoking upon mental processes, but with the effects, if any such there be, of a continued use of tobacco. A few studies of the effects of smoking in school and college students have been published. Though they are mostly inconclusive, a brief summary will be here presented (Table I.).

Table I.—*Previous Statistical Studies of Intelligence and Scholarship among Smokers and Non-smokers.*

| Number and type of observations. | Results. | | | |
|---|---|---|---|---|
| | S. N. Powers.[1] | | | |
| | Intelligence tests. | | | Scholarship grades. |
| High-school boys, 14 to 26— | Army alpha. | Miller. | Terman A. | |
| Non-smokers .. | 112·5 | 68·9 | 144·2 | 9·6 |
| Smokers .. .. | 98·6 | 57·5 | 122·9 | 8·7 |
| | E. L. Clarke.[2] | | | |
| College students, 201— | 68·5 % of non-smokers | Won honours in scholarship. | | |
| Smokers, 46·3 % | 18·3 % of smokers | | | |
| | George L. Meylan (Columbia).[3] | | | |
| | Average percentage marks— | | Percentage failures during first two years. | |
| | At entrance. | During two years. | | |
| Students, 223— | 90 .... | 66 | 7 | |
| Smokers, 115 .. | 89 .... | 62 | 10 | |
| Non-smokers, 108 .. .. | 91 .... | 69 | 4 | |
| Fraternity members, 66— | 85·0 .... | 59·1 | 12·8 | |
| Smokers, 49 .. | 84·0 .... | 56·6 | 14·4 | |
| Non-smokers, 17.. .. .. | 89·4 .... | 66·5 | 8·1 | |
| | M. V. O'Shea.[4] | | | |
| | Median standing.* | | Mean standing. | |
| | A | B | C | |
| (*a*) High-school boys, 1434, from 30 different cities. | 83·816 | 82·809 ± ·09 | 83·523 ± ·076 | |
| (*b*) 101 boys who smoke equivalent of 5 pipes weekly. | 82·375 | 81·409 ± ·34 | 82·000 ± ·275 | |
| (*c*) 40 boys, ditto, 10 pipes weekly. | 81·857 | 80·857 ± ·59 | 81·525 ± ·472 | |
| Difference between (*a*) and (*b*) .. | — | 1·40 ± ·35 | 1·52 ± ·20 | |
| Difference between (*a*) and (*c*) .. | — | 1·95 ± ·50 | 2·00 ± ·48 | |
| Number of observations not given. | Correlation between "smoking" and "scholarship," – ·51. | | | |

* If a number of observations are arranged in order of magnitude, the median is the value of the middle one. If there are 2n + 1 observations. the (n + 1)th gives the median; if there are 2n the median is the value midway between those of the nth and the (n + 1)th.

A = as given by O'Shea. B = as calculated by the author from O'Shea's figures. C = calculated by the author from O'Shea's figures.

Some of the results given in Table I. may not be highly significant, but the general tendency is in favour of the non-smokers and of the lighter smokers, and is confirmed by my own observations. O'Shea, whose study is probably the most notable of this kind, quotes more evidence from the literature pointing in the same direction.

### *The Present Investigation.*

The present research is a continuation, on somewhat larger and partly different material, of an investigation previously published,[5] into the effects of tobacco upon the students at Antioch College. In the former study cumulative scholarship was studied. This is open to the objection that when a non-smoker becomes a smoker his cumulative average continues to carry the grades which he made as a non-smoker. This would be a disadvantage if a causal relation happens to exist between low scholarship and smoking, a possibility which cannot be overlooked. In our previous study the numerical grades were based on the following equivalents.

| | | | | | |
|---|---|---|---|---|---|
| A .... | 7 | C .... | 3 | E .... | 1 |
| B .... | 5 | D .... | 2 | F .... | 0 |

We have in the present study preferred to reassess these grades as follows:—

| | | | | | |
|---|---|---|---|---|---|
| A .... | 5 | C .... | 3 | E .... | 1 |
| B .... | 4 | D .... | 2 | F .... | 0 |

This accounts for the generally lower average grades found in the present paper.

Antioch students may perhaps not unfairly be taken to represent a random sample of the college population of the United States, and that is the universe to which our conclusions must apply. The two groups, "smokers" and "non-smokers," include the great majority of men students who were present in college throughout the period under review—usually the academic year 1924–25. There is one respect, however, in which the sample of "smokers" is not truly random. We find that most of the students previously dropped for low scholarship were smokers, and therefore the remaining "smokers" (those considered in this study) include fewer of the very low scholarship group than a random sample should. The effect of this factor on the study of progressive decline in scholarship (involving a period of three years) may be considerable. It is to be noted that a correction of this factor, if that were possible, would strengthen all the conclusions to be drawn from this paper.

### *Smoking and Intelligence.*

The majority, though not all, of our students have received two intelligence tests. The Thurstone test is given before admission and is not under the direct supervision of the college. Of course, every effort is made to secure accuracy. The O'Rourke test was given at the college in the department of psychology, and the results may be depended upon absolutely.

The mean ratings of smokers and non-smokers are as follows:—

*Thurstone Test.*

| | |
|---|---|
| 167 smokers .. .. .. | 102·84 ± 1·27 |
| 165 non-smokers .. .. | 97·42 ± 1·15 |
| Difference .. .. .. | 5·42 ± 1·71 |

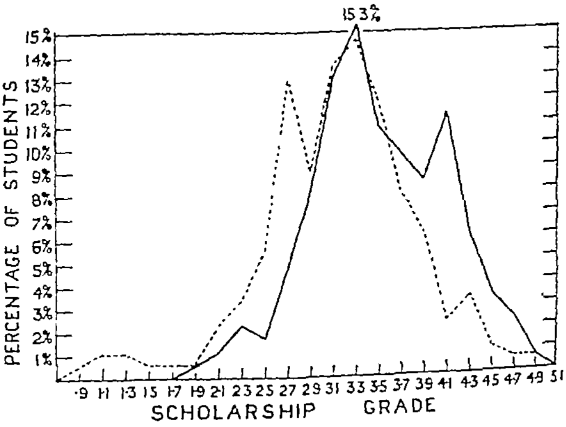
*O'Rourke Test.*

| | |
|---|---|
| 157 smokers .. .. .. | 70·72 ± 0·73 |
| 155 non-smokers .. .. | 70·05 ± 0·70 |

The difference in the O'Rourke test is less than the probable error. The difference in favour of the smokers in the Thurstone test is three times the probable error.

### *Smoking and Scholarship.*

Division of the group of smokers into sub-groups according to the amount smoked must be made by arbitrary rules and the group limits will be very roughly drawn. No account can be taken of the possible variations of toxicity of different brands of tobacco or of the wide variations in the size of pipes and the completeness of combustion. As in our previous study,[5] a light smoker uses two cigarettes, one pipe, or one cigar a day; a moderate smoker up to ten cigarettes, three pipes, or two cigars a day; and a heavy smoker more than this.



The mean grades of the different groups for the year 1924-25 are as follows :—

| | |
|---|---|
| A 170 non-smokers | 3 51 ± 0 03 |
| B 177 smokers | 3 14 ± 0·03 |
| (*a*) 44 light smokers | 3 19 ± 0·07 |
| (*b*) 56 moderate smokers | 3 33 ± 0·06 |
| (*c*) 77 heavy smokers | 3·00 ± 0·05 |
| (*d*) 100 moderate and light smokers | 3 23 ± 0·04 |
| Difference A and B | 0 37 ± 0·04 |
| Difference (*c*) and (*d*) | 0 23 ± 0·06 |

57 1 per cent of smokers and 31 8 per cent of non smokers failed to reach diploma grade (3 2) (see graph) The vertical ordinates in the graph show the percentages of smokers and non-smokers respectively who were in the grades marked on the horizontal axis. Students falling below diploma grade must improve their grade within a year or else leave college.

No student whose cumulative average is below diploma grade is allowed to graduate. Of 23 men students dismissed during the year for low scholarship 20 were smokers Of the 177 smokers, 111 are known to inhale the smoke, 50 are known not to inhale, and in 7 cases the information is lacking The mean scholarship grades of the inhalers and non inhalers are given in Table II The "expected mean grade is calculated by taking into account only the *quantity* of tobacco used irrespective of inhaling and weighting the mean grades already found for heavy, moderate, and light smokers by the numbers in these classes among the inhalers and non inhalers separately

TABLE II.

| — | Inhalers. | Non inhalers. | Difference between inhalers and non inhalers. |
|---|---|---|---|
| "Expected" mean grade | 3 12 ± ·06 | 3 19 ± ·06 | 0·07 ± ·081 |
| Observed mean grade | 3 04 ± ·04 | 3 32 ± ·05 | 0·28 ± ·067 |

The difference in favour of the non-inhalers is thus significant.

If we convert scholarship from a variable to an attribute by considering that all who fail to reach diploma grade (3 2) are afflicted with low scholarship we may then consider the association between the three attributes, low scholarship, heavy smoking, and inhaling

It would appear from Table III. that both "heavy smoking" and "inhaling" are associated with low scholarship, and to some extent independently; though the differences between the inhalers and the non inhalers are not statistically significant, they all point in the same direction The Antioch students have smoked for periods varying from one year up to 15 years. The correlation coefficient between scholarship grade and the length of time smoking has been practised is negligible (—·09 ± ·05) To test the same problem by another method I have determined for those students who had been at Antioch for three years or more the mean grade for each of the three years for both smokers and non-smokers :—

| | 1922-23. | 1923-24 | 1924-25 |
|---|---|---|---|
| Non-smokers 39 | 3 54 | 3 50 | 3 54 |
| Smokers 35 .. | 3 56 ± ·05 | 3 33 ± ·07 | 3 31 ± ·05 |

The difference in the case of smokers from— { 1922-23 to 1923-24 is 0·23 ± ·09
1922-23 to 1924-25 is 0·25 ± ·08

The decline is somewhat irregular and barely significant. This may be partly due to the fact that in the last year four students had to make special efforts to save themselves from expulsion.

TABLE III

| — | Heavy smokers. | | | Moderate and light smokers. | | | All inhalers. | All non inhalers. | All smokers. |
|---|---|---|---|---|---|---|---|---|---|
| | Inhalers. | Non inhalers. | All. | Inhalers. | Non inhalers. | All | | | |
| Above diploma standard | 22 | 6 | 28 | 27 | 28 | 55 | 49 | 34 | 83 |
| Below diploma standard | 41<br>*(65 1 ± 4·04 %) | 6<br>(50·0 ± 9 73 %) | 47<br>(62 7 ± 3 77 %) | 21<br>(43 8 ± 4 83 %) | 19<br>(40 4 ± 4·63 %) | 40<br>(42 1 ± 5 12 %) | 62<br>(55·9 ± 3 15 %) | 25<br>(42 4 ± 4 34 %) | 87<br>(51·2 ± 2 59 %) |
| Totals | 63 | 12 | 75 | 48 | 47 | 95 | 111 | 59 | 170 |

* The percentages are all taken on the totals in the bottom horizontal line

Difference of percentages below diploma grade between heavy smokers and moderate and light smokers among— { All smokers = 20·6 ± 6 1
Inhalers = 21 3 ± 6 3
Non-inhalers = 9·6 ± 10·0

Difference of percentages below diploma grade between inhalers and non inhalers among— { All smokers = 13 5 ± 5 4
Heavy smokers = 15 1 ± 10 5
Moderate and light smokers = 3·4 ± 6 8

*Discussion.*

To explain the association between the smoking habit and low scholarship there are three theories that seem to be worthy of consideration.

1 Scholarship demands the *exercise of attention* which cuts off the individual from his fellows. This solitude of mind is incompatible with the gregarious instinct. According to this theory the tobacco habit has only an incidental connexion with low scholarship by being related to the gregarious tendencies of man. The smoker smokes because it is a social habit. He has low scholarship because he is sociable If some disease yet undiscovered should strike the tobacco crops and sweep that vegetable from the face of the earth, those who now smoke would not, according to this theory, advance in scholarship They would continue to employ their leisure hours in social intercourse rather than in study The theory is supported by the observations of Dr Meylan, of Columbia though it does not suffice entirely to explain them, for the smokers in fraternities fared worse than the non-smokers in the same fraternities. I tested it for Antioch students by examining the association between smoking and membership in college societies. I found that 177 smokers provide 70 members and 113 memberships in college societies; 170 non-smokers provide 78 members and 144 memberships in college societies However, I do not press this fact as an argument against the theory because membership in an Antioch Society is often an indication of public spirit or of an altruistic "complex" rather than of the herd instinct Antioch has no fraternities.

2 *The Habit of Smoking Devitalises Ambition*—This is the theory which is expressed by Emerson in the following words "The believing we do something when we do nothing is the first illusion of tobacco" Whether the fumes of burning tobacco are poisonous or not there is no doubt that the habit once established gives rise to more or less craving for this form of indulgence. It is contended that in satisfying this craving other less insistent cravings, among them the craving for knowledge and scholastic success, tend to be neglected. The observations that "heavy smoking" is more closely associated with low scholarship than "light smoking, and that as time goes on the smoker's scholarship tends to decline are not out of harmony with this theory We should also expect to find the smoker's intelligence unimpaired, as, in fact we do

3. That some poison or poisons in the smoke acting upon the central nervous system produce a *deterioration of nervous tissue* leading directly to a lower mental output. This is the only theory as far as I can see, which would explain an independent association of "inhaling" with low scholarship The amount of time given to social intercourse by those who inhale surely cannot be greater than that given by those who do not inhale. The much greater absorption of the vaporised products of tobacco* is, indeed, the only obvious distinction which delimits the first group from the second This theory is also supported by the observations of the progressive decline in the scholarship of smokers and by the lower scholarship of the heavier smokers It is supported also by the nerve injuries known to be associated with excessive use of tobacco—e.g. amblyopia, deafness tachycardia—and by the nature of the poisons which tobacco is known to contain.

On the other hand, we have to remember that many men of great intellectual eminence and achievement have been smokers. We note, too that intelligence as measured by psychological tests is not affected by smoking. Moreover, if a chronic poisoning process of any considerable significance is taking place it is astonishing that the correlation coefficient between scholarship and the length of time of indulgence in tobacco is negligible

---

* According to R. Heinz,[4] eight times more nicotine is absorbed in inhaling than in mouth smoking

On the whole, it seems likely that more than one, perhaps more than all, of the explanations ventured above are necessary to cover all the facts.

## NATIONAL BABY WEEK COUNCIL.

THE report for 1925 of the National Baby Week Council is an encouraging record of advance in many directions. An increasing tendency is noted among local authorities to undertake continuous propaganda during a given period, by means of film displays, lectures, and demonstrations, while a considerable development of the Health Week movement also took place during the year, this being successfully combined in many places with Baby Week celebrations. Each year the Council, while drawing attention to the maternity and child welfare problem as a whole, selects certain aspects of that problem for special emphasis during the year. During 1925 the subjects thus selected were the problem of maternal mortality and morbidity in childbirth, and the psychological bases of character formation. A good deal of interest was shown by the Press in these somewhat technical subjects. The second Imperial Baby Week was held at the British Empire Exhibition, Wembley, from July 6th to 11th, and in connexion with this the Council held its second Imperial Competition, the Empire's Mother and Baby Competition. This competition included the mother as a competitor, her part consisting of answering three set questions on mothercraft appended to the score-sheet. The awards were made on the joint totals of marks of credit won by mother and baby. Three new films, "Empire Builders," "The Work of an Infant Welfare Centre," and "A Place in the Sun," proved popular. During 1925 the first International Congress on Child Welfare was held at Geneva under the auspices of the International Save the Children Fund, the National Association for the Prevention of Infant Mortality coöperating in this activity. Since, however, this necessitated the abandonment of the usual annual conference on infant welfare organised by the National Association, a summer school of maternity and child welfare was held by the Council during National Baby Week, when a large number of delegates and of private members attended from all over the country.

Baby Week is to be held this year from July 1st to 7th, the special subjects for discussion being the following: (*a*) the Care of the Toddler; (*b*) the Care of the Mother, Expectant, at Confinement, and General Postnatal Care; (*c*) the Father's Part in the Child Welfare Movement. Full particulars of this and of the fourth English-speaking Conference on Maternity and Child Welfare, which is to be held in London on July 5th, 6th, and 7th, may be obtained on application to the Secretary of the Council at 117, Piccadilly, London, W. 1.

## DR. KNOCK.

"Dr. Knock," in the translation of Mr. H. Granville Barker, which we noticed when it was published about a year ago,[1] is now delighting large audiences at the Royalty Theatre. Mr. Dennis Eadie, whose every gesture recalls the professional manner of the keen and efficient young specialist, gives a delightful interpretation of the title rôle. As a pure farce the piece is admirable, but to the medical critic it is surprising that so many of the reviewers should have seen in it nothing more. In the first place the character of the thrusting, unscrupulous Dr. Knock is by no means that of the ordinary get-rich-quick charlatan. It is true that at the beginning of his career he may have been chiefly impelled by the desire for gain, but by the end of the play, when he has transformed in three months a blatantly robust parish into a community of terror-stricken invalids in a condition of abject dependence on their medical dictator, the fascination of wielding unlimited power has taken hold of him. His monologue towards the close of the last act reveals him as an idealist who dreams of the universal reign of medical science over a world of people whose individuality is expressed purely in their clinical history-sheets. Starting with the truism that there is something wrong with every one of us, he has developed a marvellous intuitive flair for the best way of making each of his patients admit this flaw in their own constitution, and of keeping them in terror of its development and thus in thrall to himself. He called it diagnosis, but it was, of course, suggestion; diagnosis to him was the appreciation not of his patients' ailments, but of their suggestibility. The play shows him first exploiting an idea for his own ends, next succumbing to its fascination and its success, and finally pursuing it beyond all reasonable limits. The psychiatrist, looking beyond the last curtain, can see that it is only a matter of time before that idea masters him and drives him into a state of mental instability. The burlesque, applied to modern medical methods, may be extreme, but no practitioner with a sense of humour can see "Dr. Knock" and fail to recognise a certain distorted reflection of his professional self. The more experience the doctor has the more he realises that he can benefit hardly any of his patients without the aid of suggestion in some form. Every practitioner has had at one time or another to play the part of "Dr. Knock" in order to convince a patient with a painless lump that his life was in danger, and every public health officer has had to paint a vivid picture of the horrors of epidemic disease in order to persuade his community to submit to immunisation. The public gives periodical signs of resenting this, signs which range from bitterly unjust newspaper attacks on the profession to such harmless jests at its expense as this play.

## THE REVISED SYSTEM OF HOSPITAL ACCOUNTS.

King Edward's Hospital Fund for London, the Metropolitan Hospital Sunday Fund, and the Hospital Saturday Fund require that hospitals in London receiving grants from them shall adopt a uniform system of keeping accounts, and it is certainly desirable that all hospitals should publish their accounts on a standard basis so that their financial position may be compared. The Voluntary Hospitals Commission of the Ministry of Health restricts its grants to hospitals using the Revised Uniform System or other form of accounts approved by the Commission. The fourth edition of "The Revised Uniform System of Hospital Accounts" (published by Messrs. Geo. Barber, 23, Furnival-street, Holborn, London, E.C., price 5*s.* net, 5*s.* 4*d.* post free) which has just been issued will therefore be useful to all those who are interested in hospital finance. The principal feature of this system is that it provides for the complete separation of the Income and Expenditure on Maintenance Account from all other items; in the present edition the arrangement of the Income and Expenditure Account has been usefully revised. The way has also been prepared for the hospitals to develop an accounting system which, without much change in the published accounts, will enable them to ascertain the cost of each department. An appendix has been added dealing with the internal control of expenditure by quantity statistics, the budget, and departmental costs. Attention is drawn to new regulations and additions to existing regulations; all the regulations contained in the new edition should be adopted (beginning with published accounts for the year 1926) by all institutions applying for grants from any of the three funds. This publication would also be useful to those responsible for institutions other than hospitals.

## THE NURTURE OF INFANTS.

A LITTLE book[1] designed to provide mothers with detailed instructions on the feeding and upbringing of infants has reached us. The rules for management and clothing of the infant are excellent, and the lists of nursery requisites should be extremely useful. The method of feeding which Nurse Hill recommends is more open to criticism. All breast-fed babies are given one bottle of cow's milk in the day from the third week. For bottle-fed infants undiluted citrated milk, with the addition of sugar, is advocated as a routine diet from birth, and is varied by the addition of Glaxo after the first month. We doubt whether mothers of the infants will profit by taking the advice that babies require change of diet almost as much as grown-ups, but the rigid adherence to punctuality and hygienic methods which are so firmly stressed throughout the book will secure a large measure of success for this as for other modes of feeding.

THE "Quarterly Review of Biology" is published by the Williams and Wilkins Company, Baltimore, U.S.A., the English agents being Messrs. Baillière, Tindall and Cox, from whom this journal is obtainable at an annual subscription rate of 23*s.* 6*d.*

"OSMICS" is an occasional periodical published by Messrs. Oliver and Boyd, Tweeddale-court, Edinburgh.

*Corrigendum.*—In Dr. Moppett's laboratory note on the Lethal Effect of Ultra-violet Light in THE LANCET of May 1st (p. 907), the lethal dose for kidney epithelium was given as an exposure of 10 seconds. Ten *minutes* was the period intended.

# An Address

ON

# THE PRESENT POSITION OF THE TUBERCULOSIS PROBLEM.

*Given at the University of Chicago on May 10th, 1926,*

BY SIR ARTHUR NEWSHOLME, K.C.B.,
M.D., F.R.C.P. LOND.,
LATE PRINCIPAL MEDICAL OFFICER, LOCAL GOVERNMENT BOARD.

PERHAPS no single disease has been so fertile as tuberculosis in divergent views as to its causation and as to means for its prevention; and these differences of outlook continue notwithstanding our certain knowledge that in the absence of the tubercle bacillus there can be no tuberculosis. For it is common knowledge that minor degrees of infection need not cause actual disease, and that many unfavourable hygienic circumstances excite into activity an amount of infection, which in their absence might have remained permanently dormant. Hence there is a corresponding difference of opinion as to the principal factors which have led to the astounding result embodied in the statement that the death-rate *from respiratory tuberculosis*, which in England and Wales in 1871–75 averaged 2·22 per 1000 of population, *had become 0·84 in 1924*, a decrease of 62 per cent.

The problem is one of profound interest and practical importance, not only because differences of opinion as to the causation of this reduced mortality continue and are responsible for much lassitude in effort towards further reduction; but also because, *notwithstanding the vast improvement just indicated, tuberculosis continues to be one of the chief causes of death, and perhaps the most frequent source of adult disability, and of the production of dependent widows and children. In 1921*, in England and Wales—

| | | |
|---|---|---|
| Tuberculosis (all forms) caused | 41,103 | deaths, |
| As compared with— | 50,380 | from cancer, |
| | 37,786 | „ bronchitis, |
| | 30,910 | „ pneumonia, |
| | 60,650 | „ cardiac diseases. |

The items thus tabulated are not strictly comparable, for tuberculosis when fatal is usually the predominant disease, whereas bronchitis and pneumonia frequently are secondary to other infections or to non-infectious diseases; and cardiac diseases should be regarded as the end-product resulting from earlier infections, especially by the rheumatic virus and the *Treponema pallidum*.

Furthermore, from an economic standpoint, tuberculosis may be regarded as more important even than the 51,813 deaths which in 1921 occurred in the first year after birth. All life is valuable, and death at the beginning of life has an importance all its own, not only because of promise destroyed, but also because mortality at this age is an unfailing index of a much greater amount of "sickness not unto death," which leaves its traces in weakness and incapacity in later life.

From our present point of view the difference between cancer and tuberculosis is clearly shown in Fig. 1, from which we can ascertain whether the chief incidence of deaths has been in the most fruitful years of life, or whether these deaths have occurred chiefly after the victims have paid back the debt to society which they have incurred in their birth and their upbringing.

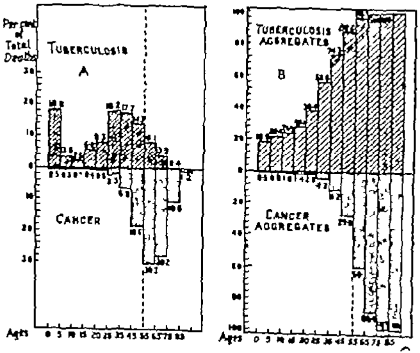
It will be seen that tubercle has killed 96·7 per cent. of its total victims before they reach the age of 65, while cancer at the same age has only secured 60 per cent. of its total victims. Both diseases, however, have supreme importance in view of the fact that more than half of the total mortality from each of them occurs at the working years of life, 20–65.

### *Age and Sex.*

The vital statistics of age and sex, and of local incidence of tuberculosis throw important light on the problems of tuberculosis already partially solved or remaining to be solved; and we may profitably spend a few minutes in considering them. Let us consider first the age and sex incidence of total tuberculosis in males, as shown in the English figures for 1912–14 and 1923 (Fig. 2). The same figure shows also the reduction of death-rate which has occurred at different ages. With the single exception of the age period 20–25 there has been a marked decline at all ages, the reduction in the peak in adult life 25–65 being very striking.

*The female curves for the two periods show similar declines at all ages except 15–25; and it would appear that at these ages, as also at ages 20–25 in men, some unfavourable influence has emerged, associated with unemployment, with the increasing migration to towns and the increase of indoor industrial occupations both for men and women.*

FIG. 1.



England and Wales, 1901–10: A. Percentage of total male deaths at all ages from tuberculosis and cancer which occur at each age-period. B. Ditto at each and all lower age-periods. Taken from the author's "Elements of Vital Statistics" by kind permission of Messrs. Allen and Unwin.

### CHILD TUBERCULOSIS.

The marked reduction of registered tuberculosis in the first five years of life calls for separate comment. Prior to 1910 the death-rate at these ages was higher than that at any subsequent period of life; but latterly this has ceased to be so, probably because with increasing accuracy of registration, deaths formerly ascribed to tabes mesenterica or to tuberculous meningitis are now only so returned in most instances as the result of more careful weighing of evidence. That there has been a real decline in tuberculosis at ages under 5 is undoubted, for these ages can scarcely have escaped the influences causing a reduced death-rate at higher ages. It would appear that some of the decline shown in the curve at ages 0–5 is actual, while some is due to changes in death certification. This, however, does not complete the story as to tuberculosis in childhood. Owing to difficulties in diagnosis it is probable that many deaths from acute general tuberculosis in childhood remain unrecognised, and that many cases, for instance, of so-called bronchitis and broncho-pneumonia, represent a rapid explosion of acute tuberculosis.

Even if we take the official figures at their face value, and assume that there has been as large a decrease in child tuberculosis as is shown in them, it is none the less true that in childhood the tubercle bacillus still claims a vast number of victims, probably more than at any later age-period of life. Hence one of the most urgent problems to be studied in public health administration, and in the work of every practitioner in medicine, is *how to minimise risks of infection during the first five and especially during the first two years of life.* The removal of risk from infected milk or its great reduction only covers a fraction of the danger; for exact observation has shown that only a minority of cases of non-pulmonary tuberculosis, the chief form of tuberculosis in children, are of bovine origin. The continuance and extension of precautions in respect of milk is most important; but this alone leaves the major problem of prevention of infection, that from human sources, unsolved.

The study of the epidemiology of tuberculosis, as elucidated by Dr. G. E. Bushnell, by Metchnikoff, Calmette, and others appears to point to the conclusion that each infant at birth may be, and probably is, in a similar position in respect of tuberculosis to that of remote races when first exposed to this disease. Both in children and in the adults of hitherto non-tuberculous communities when invaded by tuberculosis there is a very high mortality and the tuberculosis is of an acute and rapid type. Even in urbanised communities like England the high peak of mortality in the first five years of life, a peak which is probably now understated (Fig. 2), may be regarded as good evidence of the initial lack of immunity of young children. Those children who receive smaller doses of infection become "naturally vaccinated" (Metchnikoff), or it is conceivable that in some instances larger doses are resisted by children with higher resistance. Thus after infancy the survivors in thickly populated countries secure a partial immunisation against tuberculosis in later life. It has been suggested that this partial immunisation may be produced by tuberculous cows' milk derived from a mixed herd; but there is no evidence of this so far as respiratory tuberculosis is concerned; and as regards non-pulmonary tuberculosis, which is commonly not fatal, its strikingly reduced frequency is more satisfactorily explicable by the fairly general substitution of pasteurised for uncooked milk and by the reduction in human sources of infection.

### RACIAL SUSCEPTIBILITY AND CHILD INFECTION.

The facts as to child tuberculosis do not necessitate the assumption that there exist real racial differences in liability to fatal tuberculosis. The experience of the Irish and Negroes at one end of the scale and of Jews at the other, is commonly adduced as indicating real racial differences. It is difficult, however, to separate the essential influence of heredity in race from collateral differences of social life, of personal habits, of cleanliness, and of varying degrees of exposure to infection; and it is preferable therefore to suspend judgment under this heading.

There remains, as already indicated, the question as to why certain children survive and others perish after infection by tuberculosis. The two results are seen in the same mixed community and in the same family; and although it may be that in the same family, for instance, differences of susceptibility occur, the difference is most naturally explained by assuming that what follows—whether partial immunisation or death—depends primarily on the number of occasions on which infection has been received and on the aggregate dosage of this infection. The somewhat comparable case of diphtheria comes to mind. The infant at its birth appears to possess some partial immunity, probably derived from the maternal circulation. This disappears, but later, as shown by the Schick test, the child develops its own immunity, as the result of minimal doses of casual infection, unless before this happens it is infected by an overwhelming dose of infective matter.

But the case of diphtheria suggests another possibility—*viz.*, that immunity is acquired by infection from a less virulent type of diphtheria bacillus and is not merely consequent on a reduction in the number of invading bacilli; and may not this also occur in tuberculosis? There is no direct evidence as to this, but whether it be so or not, if Calmette's current experimental work is confirmed, there may be opened out great possibilities of protection of children in consumptive families in this direction. Meantime it is a counsel of practical wisdom to assume that minimum dosage of virulent bacilli occurs in instances of safe recovery from tuberculous infection; and on this assumption public health administration must regard itself as anxiously concerned to adopt measures which will minimise during childhood exposure to infection from tuberculous patients. This emphasises the importance of continuous and detailed care in respect of housing for tuberculous adults, including the inculcation of careful precautions as to coughing and fondling, as to cleanliness of hands and handkerchiefs, and the provision of separate bedroom accommodation, either at home or in a sanatorium or hospital. Even if cases of open tuberculosis cannot be continuously segregated—whether functionally at their homes, by the taking of rigid precautions and by separate bedrooms, or geographically in institutions—this can be done intermittently, and there is every reason for believing that discontinuity of infection greatly reduces risk of effective infection of the exposed. The alternative plan of removing children to summer or seaside homes is sometimes practicable, and this has a range of utility which has been more fully appreciated in France than in England.

The special need to protect children during the first few years of life will remind public health workers of the similar need for preventing children of the same age from acquiring measles, as it is then many times more fatal than later in life. Both child hygiene workers and tuberculosis workers should increasingly act in the closest combination if infants are to be safeguarded against tuberculous infection, from which they have not yet had time to acquire partial immunity by gradual and small-dosed infection; and here is, in my view, one of the most promising and fruitful lines of public health work. According to a statement of Landouzy some years ago, 27 per cent. of the total deaths from all causes in the first two years of life are due to tuberculosis. The English official records give this proportion as only 3·3 per cent. The truth lies somewhere between these two extremes; but even the lower figure means that mischief is so great as to call for more strenuous efforts for the protection of young children. It is significant that a large part of this danger occurs in the "crawling" stage of childhood, and the need for avoiding infection of toys and fingers at this stage is very great.

### RESPIRATORY TUBERCULOSIS.

After childhood respiratory tuberculosis is the chief form of fatal tuberculosis; and we next consider the age-incidence of respiratory tuberculosis (Fig. 3). It will be noted that for England and Wales as a whole (Fig. 3, A) in 1923 the death-rate from phthisis in females reached its maximum at the age-period 15–25, being only slightly lower at the age-period 25–35, while for males the highest death-rates were at ages 35–55. It will be noted, furthermore, that at the age-period 15–25 the female death-rate was higher than that for males. At all later ages the male is higher than the female rate; and it is evident that men are exposed to infection, or to inimical influences which bring infection into dangerous activity, to a much greater extent than are women. Some light on this point is thrown by contrasting the curve for males in rural districts (Fig. 3, B) with that for females in England as a whole. These two tend to approximate, but even in rural districts the death-rate of men aged 25–35 is much higher than that of women generally. How far migration to and from towns affects these results can only be guessed.

The difference between males in rural districts and in the larger towns is striking (Fig. 3, B). Living and working in our great towns, with the added dissipations of town life, imply a heavy additional phthisis rate, though happily the difference between urban and rural death-rates, as decade follows decade, is declining

Perhaps the most striking curves are shown in Fig 3, c There is a remarkably small difference between the urban and rural death rates for women; and it would certainly appear that tuberculosis need be no more serious a disease in town than in country This is explicable in several ways. It may be regarded as additional evidence that the sources of danger in urban life are industrial and convivial—e.g , in public houses, from both of which dangers women commonly escape. An additional factor may be that consumptive men in towns can obtain institutional treatment at an earlier date and longer in duration than is obtainable in rural districts, and their families receive less massive infection than rural families This last difference, if it exists, will gradually disappear; and the increasing proximity of the rural to the urban death rate from phthisis points in the same direction

FIG 3

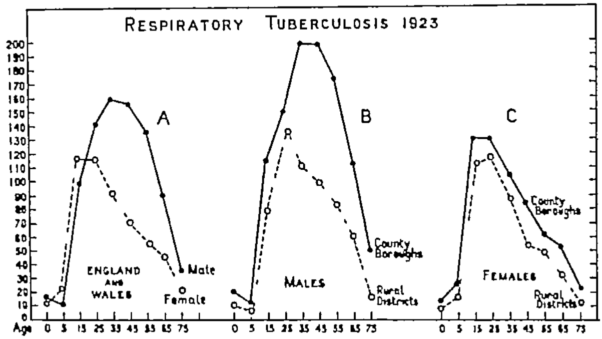


FIG 2

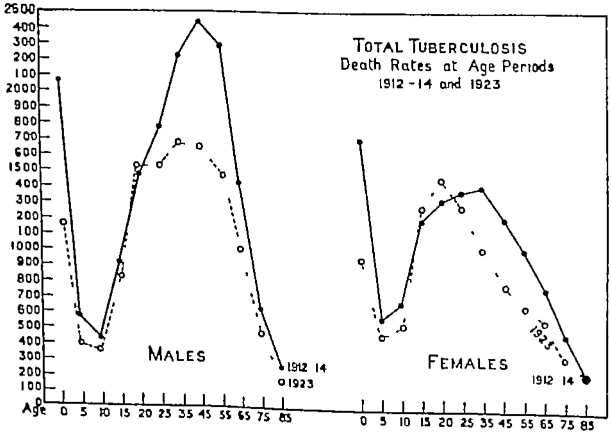


In different countries, in various parts of the same country, and at different periods, Dr J Brownlee has shown that the age-incidence of maximum death rate from phthisis may occur in early adult life, say 20–25 years, in middle age from 45–55, or in persons over 55, and has suggested that these variations may imply that phthisis is a group of three diseases But the fact that in different parts of the same country and in the two sexes each of these types of age-incidence may be seen at the same time does not support this hypothesis, and it is more in accord with our general knowledge of the disease to maintain that the differences in age-incidence of phthisis at different periods and in different communities are due to the varying extent to which the causes of tuberculosis are at work. The disease tuberculosis is the product of two sets of circumstances—an adequate dosage of infection, and conditions favouring or impeding successful invasion of the disease; and as both dosage of infection and circumstances favouring its development vary greatly in different communities and social strata, it is reasonable to anticipate differences in age and sex distribution of the disease, the hypothesis of three types of disease being unnecessary.

We may next examine the historical course of the death rate from all forms of tuberculosis. This is shown for England and Wales in Fig 4, reproduced from a chart prepared for the New York Tuberculosis Association Two things stand out in this diagram, first, the steady and continuous course of decline, which is unmistakable since the early 'seventies; and secondly, the fact that as the amount of pulmonary tuberculosis declines, so still more does that of non-pulmonary tuberculosis.

### RATE OF DECLINE.

The curves for New York City and for the registration area of the United States, derived from the same source, bring out the facts that (1) although the death-rates are higher than those in England, they show since 1000 a similar decline, with a much smaller interruption in 1018; and (2) they further illustrate the point already made earlier in this address that the city death-rate is rapidly approximating that of the registration area of the United States as a whole, the population of half of which is still in rural districts. Similar curves dealing with respiratory tuberculosis in England and Wales bring out the steady decline in the phthisis death rate from 1870 onwards Evidently for a long series of years, in the complexity of modern social and economic conditions in England, factors have been at work which on balance have led to a steady rate of decline of the tuberculosis death-rate; and there is no confirmation of the title or the substance of Prof. Pearson's contribution to *Biometrika* (1018-10, vol xii ) on "The Check to the Fall in the Phthisis Death-rate since the Discovery of the Tubercle Bacillus and the Adoption of Modern Treatment" There had been no check in the rate of decline prior to the Great War.

*It is true that in 1924 the national death-rate* from phthisis was almost the same as in 1923, but it was lower than in any preceding year; and we must have the experience of several more years before we can begin to think that the English death-rate is incapable of sinking as low as, or lower than, the present New Zealand death-rate shown in Fig. 5.

### CAUSES OF DECLINE.

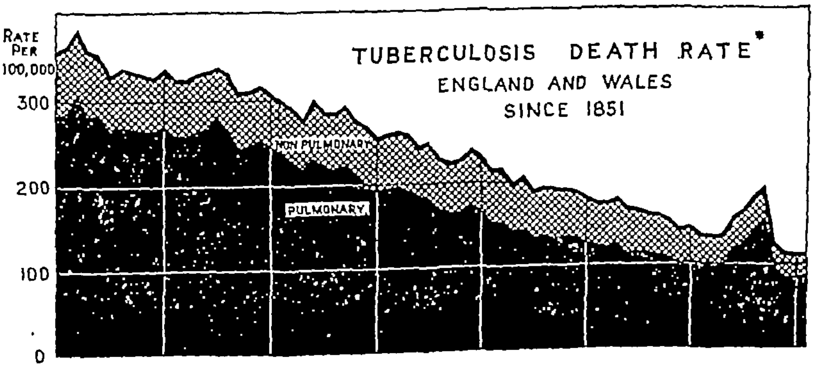
I have referred to the influences causing decline of tuberculosis in England and in other countries. What have these been? What, for instance, has been occurring to cause the improvement shown in several countries, though to a varying extent, in Fig. 5, also derived from the Research Service of the New York Tuberculosis Association?

### MEASURES DIMINISHING INFECTION.

I limit the inquiry to the human which is the major source of tuberculosis in man. Two changes must, in my judgment, be placed first in order of importance: (1) There has been a great improvement in the cleanliness of the population, domestically and industrially, especially in regard to coughing and expectoration. The magnitude of this improvement it would be difficult to exaggerate. It amounts to a revolution in personal habits, the exceptions to this statement being few as compared with the experience of a few decades ago. (2) Along with this has proceeded a great improvement in the treatment of disease generally, and of tuberculosis, both at home and in hospitals. Carefully closed and warm bedrooms occupied in common by sick and well have been replaced largely by separate and well aerated bedrooms for the sick; and a steadily increasing proportion of the sick are treated in hospitals.

In 1869–70 the death-rate from respiratory tuberculosis in England and Wales was 244 per 100,000 of population. At that time 8·3 per cent. of the total deaths from all causes occurred in public institutions. In 1919–20 the phthisis death-rate was only 92 and the proportion of institutional deaths was 24·3 per cent. Taking the whole of England and Wales it is noteworthy that over a third of male deaths and more than a quarter of female deaths from phthisis now occur in hospitals, commonly after prolonged and often repeated stay of the patients in these institutions. For London about half the total deaths from phthisis occur in institutions; and the proportion in large American cities is quite as high.

FIG. 4.



The present universally accepted policy for cases of open tuberculosis is to urge that every possible precaution against infection shall be taken, and that whenever practicable institutional treatment shall be secured, at the least during acute exacerbations of disease. It is not unreasonable, to put the matter at its lowest, that the same practice which is now universally regarded as important in the interest of the community, should have borne a large share in bringing about the historical reduction of phthisis mortality which has been experienced. And we know that this practice has been increasingly in operation. As factors opposing reduction of phthisis have increased—more dense aggregation of populations, replacement of outdoor by indoor occupations, and the reduction of house room which always goes with town life—so has the hospitalisation of consumptives increased; and hospitals from this point of view must be regarded as an important, indeed an essential, extension of housing accommodation in modern circumstances of life. The more important factors for and against reduction may be thus summarised:—

*Factors Making for Reduction.*—(1) Gradual substitution of small-dosed and infrequent in lieu of large-dosed and frequent infection, and especially (*a*) increased cleanliness in personal habits (spitting, &c.), (*b*) reduction of dust and of infection in industrial life, (*c*) better care and segregation of the sick. (2) Increased resistance by improvement of general hygienic conditions, including improved nutrition, and diminution of industrial dust. (3) Provision of means for prompt diagnosis and continued treatment of tuberculosis, dispensaries, residential institutions, open-air schools, &c.

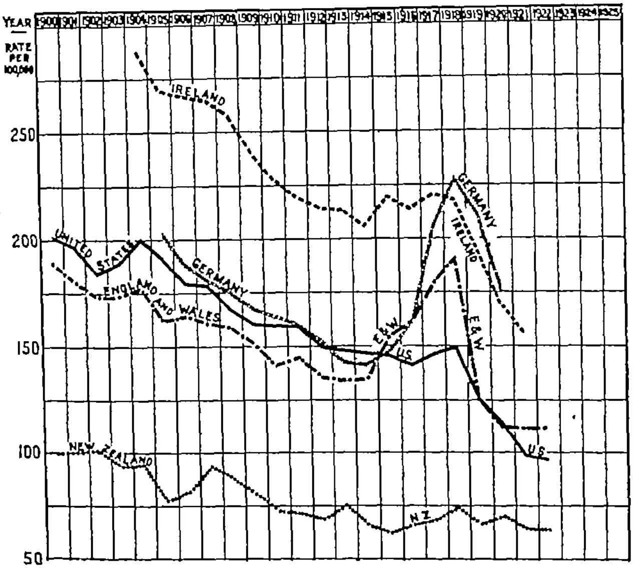
*Factors Opposing Reduction.*—(1) Steady increase of town life. (2) Increasing replacement of outdoor by indoor occupations. (3) The reduction in house-room which goes with town life.

The experience of Norway which I have discussed elsewhere need not be further emphasised here. It offers a crucial instance of the effect of segregation in reducing almost to the point of extinction a chronic infective disease like leprosy, which, although much less actively communicable, has many points of resemblance to tuberculosis. From other European countries leprosy had already disappeared; but in Norway it lingered until a steady system of segregation of cases was practised. Sir Leonard Rogers has shown a similar course of events in some other countries in which segregation of known cases has been introduced.

### INFLUENCE OF NUTRITION.

It will be remarked that improved nutrition appears also in the preceding tabular statement as an important factor in reducing mortality from tuberculosis. There is some ambiguity in the use of this phrase, just as there is in the diagnosis of malnutrition in a large proportion of the children attending school. In the latter case, unless a further analysis is pursued, the implication is that what is needed is more milk and other foods. Commonly this is the need; but the malnutrition may be caused also by some disorder or disease requiring treatment, by deficient sleep, by general defects of hygiene, or some other cause; and a "nutrition clinic," in the sense of a scientific, including a social, diagnosis of the special case is called for before we decide that the supply of additional food is the only or even the main necessity. So also when it is assumed that better and more abundant food is largely responsible for the lowered mortality from tuberculosis, one cannot be satisfied with this imperfect analysis of circumstances. Improvement in cheapness and abundance of food and in purchasing power has been associated historically sometimes with large and sometimes with insignificant reductions in the death-rate from tuberculosis; and even in the treatment of tuberculosis, over-feeding, in the sense of high calories and especially of a large meat diet, plays a much smaller rôle in the attempt to increase resistance to the intruded infection than, in the minds of physicians, it has done in the past. This is true for nutrition as stated in terms of calories. Whether it is so for special articles of diet is not so certain. In view of our rapidly increasing knowledge of the specific value of auxiliary foods and allied substances in the prevention and treatment of scurvy, rickets, goitre, and beri-beri, it is conceivable that some deficiency in the dietary of the Irish may play a larger part in the excessive death-rate from phthisis shown in Fig. 5 than an appeal to special racial proclivity, in which we are too ready to find refuge. It is still more likely that better treatment of tuberculous patients, improved housing, and a growing appreciation of the need for cleanly habits have borne a chief part in the reduction of the Irish phthisis rate shown in recent years.

FIG. 5.



Death rates from pulmonary tuberculosis, 1900–23, in various countries.

### OTHER FACTORS IN THE WAR.

And it may be that the lack of certain special elements of food—especially fats—played a considerable part in causing the increase in the death-rate from tuberculosis shown in Fig. 5 in the English and German curves during the war. Defective nutrition, whether of some specific character or more generally, doubtless played a part in bringing about what earlier in this address I have called effective infection. But other factors were at work, and it is difficult to ascribe to each of them their true weight. In England nearly all workers suffered during the war from overwork, itself a factor facilitating and liberating infective material. There was an enormous increase in the industrial employment of women, who were commonly aggregated in special centres in circumstances of overcrowding. Then in 1918–19 there occurred the terrible invasion of influenza, which, as shown in the English experience of influenza in 1889–90, means an excessive and hastened mortality among tuberculous patients. The coincidence of the two events in the more recent experience is shown below.

*Death-rates per Million Living among Females.*

| | | 1915 | 1916 | 1917 | 1918 | 1919 | 1920 | 1921 | 1922 |
|---|---|---|---|---|---|---|---|---|---|
| From influenza | Fem | 272 | 232 | 183 | *2944* | 1101 | 355 | 226 | 559 |
| „ respiratory tuberculosis | Fem. | 915 | 920 | 975 | *1070* | 656 | 757 | 777 | 766 |
| | Male | 1410 | 1447 | 1625 | *1615* | 1173 | 1003 | 1002 | 1024 |

The influenza epidemic undoubtedly bore a share in increasing the phthisis death-rate in 1917–19. So also did the circumstances of overcrowding and overwork of war time. The great improvement in infantile mortality during the war, the vast decrease in alcoholism and its consequences, and the release of an unusual proportion of greatly increased earnings for food, makes it unlikely that English civilians suffered severely from malnutrition, except as regards butter and other fats, which may be regarded as having special importance

*Heredity.*—In the preceding rapid sketch I cannot pretend to have more than indicated some of the problems associated with the incidence of tuberculosis. Nor have I enumerated all these problems. There are still some among us who attach importance to heredity as an important predisposing influence in the causation of tuberculosis. With advance of knowledge this view becomes increasingly nebulous; and most of us probably are convinced with Robert Koch (quoted by Dr. William H. Welch) that "predisposition is merely proximity to the bacillus." The terrible toll—probably much understated in the official figures—taken by tuberculosis on child life does not support the view, that in increasing proportions the survivors in successive generations have gradually become more resistant to tuberculosis than in the past. The truth rather lies in the statement that infants in every community and adults who have lived remote from urban conditions, especially in primitive life, are both alike in not having run the gauntlet of repeated small doses of infection, and are therefore prone to suffer from acute general tuberculosis.

*Cyclical Factors.*—Nor can we be said to possess satisfactory evidence of cyclical factors in the epidemiology of tuberculosis, to which importance is sometimes attached. It is futile to base such an hypothesis on the proportion of deaths from phthisis to total deaths from all causes, unless it is proved that the variability of one quantity of the total deaths can be eliminated from the proportion. Even were such cyclical changes to be demonstrated, and tuberculosis were thus placed in the same category as, for instance, influenza, cerebro-spinal fever, diphtheria, and scarlet fever, the classification would add but little to our knowledge. To rest in such a classification is to invite mental and moral sterility. We need to remind ourselves that but a few years or decades have passed since malaria, yellow fever, plague, enteric fever, and cholera were quite legitimately—and even now can be—placed among diseases influenced by imperfectly known cyclical conditions. But they have all been brought within the range of active preventive measures, and no one is disturbed by the consideration that if our present preventive measures succeed in eliminating any or all of these diseases a non-immune population will result from our efforts. In England enteric fever is losing its annual seasonal autumn rise, it has almost ceased to increase greatly in prevalence in warm and dry years; and we look forward to the rapidly approaching time when it will have become as nearly extinct as typhus fever. And we may content ourselves with the reflection that although for many generations to come it is unlikely that the majority of the people in civilised countries will cease to be invaded by diminishing doses of tubercle bacilli, there is no reason why, given the universal application of knowledge already in our possession, the reduction of the present death-rate from tuberculosis should not continue, thus removing from our midst one of the chief causes of poverty and social misery.

## FUTURE ACTION.

After this necessarily incomplete review of some of the factors concerned in the prevention of tuberculosis, we may in conclusion name some practical considerations arising from it. Our chief aim must be to minimise infection, especially at the most susceptible ages, and to promote all efforts of child welfare work and every branch of public health work which, whether by controlling epidemic diseases, by improving housing, or by securing improved occupational circumstances, will diminish the risk of arousing latent infection into activity or of renewing and increasing infection. In short, tuberculosis work is a branch of public health work and must be carried on as such, though, of course, not necessarily by the same workers.

Our working of tuberculosis medical organisations, dispensaries, sanatoriums, hospitals, &c., has emphasised the need to link them up with general medicine. This has been evidenced in the detailed work of sanatoriums and hospitals, where physicians and surgeons other than those having special skill in tuberculosis are occasionally required, and particularly in tuberculosis dispensaries, where coöperation between physicians in private and public practice is especially desirable. The ideal towards which the tuberculosis dispensary should approach is that of becoming one division of a medical or health centre for each unit of population, intended for medical consultations in different departments of medicine, and where consultations can take place not only between general practitioners and the staff of the centre, but also between the staff of different parts of the centre. Pending the development of such a general system of consultation services, the present official medical arrangements for the control of tuberculosis need more general support and extension. I need scarcely emphasise in this address the value of free expert medical examination in doubtful cases of tuberculosis, the need for additional hospitals for consumptives, the need for better use of sanatoriums, for the introduction of occupational therapy, and for special workshops for the sick, the need for the employment of many additional visiting nurses, for open-air schools, and for extended care and after-care of tuberculous patients.

Even in the most completely organised city or town it is doubtful whether anywhere the problem of tuberculosis can be said to have been tackled on a scale equal to the needs of the case. There has been too often an impression that when the reporting of cases of tuberculosis has been made obligatory, when laboratory facilities have been provided for examination of sputum, when occasional means for securing an expert medical examination of the invaded family are available, when a public health nurse having a preposterously large visiting-list is provided, when here and there a consumptive is treated for many months in a sanatorium, enough has been done to justify us in being surprised at the absence of startling statistical results. We need to think of the work needed in terms which are commensurate with the magnitude of the problem.

I suggest the following elementary questions as needing to be asked respecting any local arrangements for the control of tuberculosis:—

How do the number of cases of tuberculosis reported compare with the number of deaths from this disease?

How soon after commencing attendance does the practitioner notify his cases?

In what number of doubtful cases is consultation arranged between the practitioner and the tuberculosis officer?

In how many of the cases notified has a medical examination of the rest of the family been secured?

In how many of the cases notified has sanatorium or hospital treatment been provided?

Does the number of hospital and sanatorium beds for tuberculous patients equal the annual number of deaths from tuberculosis?

During institutional treatment has it been an essential part of the arrangements to instruct and train the patient in the hygiene of his future life?

While the patient is away from home have his domestic conditions been investigated, the condition of health of his family ascertained, and such assistance given as is needed to maintain nutrition, or directly or arranged from collateral sources?

After each patient has left the institution, has he been the subject of continued sympathetic visitation and of help to ensure that he has (*a*) occupation adapted to his physical ability, (*b*) a separate bedroom, (*c*) such supplementation of income, when needed, as will secure him from malnutrition.

I might enlarge the list of questions; but the above suffice to show that as work becomes more valuable, more and more work is needed. This is true of good work in every department of life. Efforts to combat evil reveal further avenues for such work. This work is well within the financial ability of every community, and it is equally certain that if undertaken it will repay manifold in the improved health and efficiency of the community. Let me sum up some of the practical points which need to be emphasised.

1. The objects of all antituberculosis measures are to increase the resistance of mankind to infection, and to reduce the amount and frequency of infection to which mankind is exposed.

2. The amount and frequency of infection are greater in consumptive families; and commonly, owing to poverty and its associated circumstances, the resistance to infection is at its lowest in such families.

3. The age-incidence of mortality from tuberculosis shows that the risk of acute tuberculosis and death is greatest in the first two or three years after birth. Hence the supreme importance of protecting young children against infection.

4. The excessive incidence of tuberculosis in early childhood and the important part played by epidemic diseases in increasing tuberculosis emphasise the extreme importance of connecting tuberculosis work and child welfare work closely together and of affiliating both to general public health work.

5. Steady educational work is required until the public realise that our present antituberculosis work is sound and beneficent, and that it needs to be extended in every direction. Until we are in a position to say that in every area every tuberculous patient is receiving throughout the whole of his sick-life such care as will give him the best chance of recovery, and which, whether recovery is possible or not, will secure comfort for him, and protection against infection of all who are associated with him we cannot be satisfied. When this can be said, the present rate of decline in the death-rate from tuberculosis will become more rapid, and one of the chief causes of present suffering and distress and the burden of dependent widows and children which follows later will be very greatly decreased.

---

THE Commander-in-Chief recently performed the opening ceremony of the Connaught Military Hospital at Poona. The hospital occupies the site of the old Station Hospital, which has been much enlarged and equipped with all the latest improvements.

# ADVANCE IN MEDICINE.

## WITH REFERENCE TO THE CAMPAIGN AGAINST TUBERCULOSIS.

*An Address delivered before the North-Western Tuberculosis Society at the University of Liverpool on March 18th, 1926,*

By J. G. ADAMI, C.B.E., M.D. Camb., F.R.S.,
VICE-CHANCELLOR OF THE UNIVERSITY OF LIVERPOOL.

It is as a pathologist, I take it, that I am asked to address you, and thus you will forgive me if I speak as a pathologist at large, whereby I mean not according to the more limited and Teutonic meaning of the term as a morbid anatomist pure and simple, but as a student of disease, its causes, course, and results. And as tuberculosis is an infectious disease it follows that, dealing with it, I clearly include bacteriology as part of pathology, nay more, that what I shall have to say must of necessity deal largely with bacteriological data and bacteriological considerations.

I do this the more willingly, since this occasion gives me the opportunity to take up the cudgels on behalf of the pathologist and of pathological advance. In the annual report of the Medical Research Council for 1923–24, published a year ago, its distinguished secretary passed a grave reflection upon pathology in general and British pathology in particular, pointing out that while physiology has of late been progressing by leaps and bounds, pathology, including bacteriology, has been largely at a standstill, particularly in this country, and regarding the pathologists and bacteriologists of to-day as mere laboratory routinists, slaves of the hospitals on the one hand, of the municipal authorities on the other, whose lives are not given over to research but to the provision of diagnoses.

Now, there is a sufficient substratum of truth in these accusations to make them sting. It is quite true that pathology originated in the hospital deadhouse, that the earliest pathologists, from Morgagni up until the middle of last century, and in this country up to 1880 or so, were exclusively practising physicians and surgeons, men of the type of Hunter, Addison, Bright, and Paget, and it is as an outcome of this old tradition that pathology remains closely associated with the hospital, with all the great advantages and certain great disadvantages that accrue from this association.

Physiology, the study of the functions of the body in health, had no such essential association, and in fact, its great weakness until the early years of this century lay in its attempt to regard itself as a pure science, separated from medicine. And if Sir Walter Fletcher, himself a physiologist, exults, and exults with justice, over the extraordinarily good work accomplished by the physiologists of to-day in advancing the science of medicine, it is proper that he should keep in mind that that work demonstrates its practical value precisely as it becomes pathological—i.e., as it becomes applied to the study, not of the healthy body, but of disease. He forgets that each and every experiment devised, be it in a physiological or in a pathological laboratory, upon the elucidation of any one function of the body, is a physiological experiment so far as it throws light upon the normal functioning of the body, is pathological so far as it illuminates that excessive or defective function which constitutes disease: for all disease is the outcome of either excessive or defective function. Increasingly during these post-war years the physiologists have trespassed into pathological territory; until now, for example, Sir Walter Fletcher claims this territory as their own, and evidently has reached the point of doubting whether pathology has any *raison d'être*—whether, in fact, it is a science at all. He and his friends go so far as to hold that the basis of all pathology, the study of inflammation, and of the reaction to injury, is essentially a physiological problem because, forsooth, these reactions are the normal properties of the individual and his tissues, and I suppose they would add that injury is the normal healthy condition of affairs.

What, then, is the truth? A science is not a study associated with some particular form of technique needing particular equipment. Were that so, then assuredly neither physiology nor astronomy, nor, indeed, pathology, are sciences. Just as astronomy is the study of the celestial bodies and comprises everything that has to do with them, their light, their movement, their attraction one to another, their dimensions and composition, so is pathology the study of all that we regard as disease, as distinguished from ease, and there, as a science, it has its limits. And to object that little advance is being accomplished by British pathologists and bacteriologists of to-day is, in the first place, not to estimate justly the work now being undertaken in the university and hospital laboratories of the country, and in the second not to grasp the principles underlying advance in any one science.

The interesting point is that 30 years ago identically the same complaint was being made over the English-speaking world regarding the physiologists—they were not advancing, they were concerning themselves over abstruse problems that had no possible practical application. I remember hearing one rude and outspoken member of a university staff remark that all the elaborate investigations of Burdon Sanderson, Gotch, and others upon the isolated muscle-nerve preparation might with equal edification be performed upon a piece of chewed string. And in medical schools the physiologists were credited with being "remote, unfriended, solitary, slow."

Of course, these criticisms were as unfair as they were rude. These apparently barren years, we now see, were very far from barren. The painfully intense work then accomplished was leading up among other things to the electrocardiograph and a complete revolution in our understanding and treatment of cardiac disease, to a like revolution in our understanding of respiration, to our present methods of diagnosis and treatment of digestive disturbances, to our huge advances in a knowledge of metabolism, and, with this, to the development of physiological chemistry and biochemistry as distinct departments, and, in short, to the happier conditions of to-day when physiology and medicine have realised their dependence one upon the other.

### The Causation of Infectious Disease.

I am, you will recall, addressing you on the subject of "Advance," and I trust you will forgive me if I build up a little slowly, but all the more surely, my main, or shall I say ultimate, thesis of advance in tuberculosis. Let me, as leading up thereto, take up next the broad subject of the causation of infectious disease in general. What is the story? Is it not that of long centuries in which brilliant hypotheses as to the existence of living but invisible germs of disease from time to time held a temporary sway, until at length in the second quarter of the nineteenth century, with the development of the microscope, certain of the grosser micro-organisms were found constantly associated with particular conditions: Goodsir, for example, in 1826, finding sarcinæ associated with a group of cases of gastric inertia and dilatation, and following this, Schoenlein in the 'thirties finding his achorion associated with favus, Pollender in the 'forties and Davaine in the 'fifties discovering a similar constant association between anthrax and the relatively large bacillus of that disease. Then, following the botanical studies and descriptions of the bacteria by Ferdinand Cohn, we come to the real foundation of morbid bacteriology by Past
and Koch in the late 'sixties and early 'sevent
And with that, within the next 20 years, the
vellous development of the new science—followi
upon the demonstration of an easy and practica
method of obtaining pure cultures and of st
and detecting bacteria—and the laying down of Ko
postulates. What a marvellous time it was, with t
rapid discovery one after the other of the causati

organisms of a veritable host of diseases of men and animals! And then swiftly following upon the heels of these discoveries, the development of our knowledge of immunity, of ectotoxins and endotoxins, of vaccines and immune sera. As medical men we were transported into a new world. As regards the infectious diseases, the text-books of medicine written prior to 1880 became of little more than antiquarian interest. And then from 1895 to 1905 the tide of advance slowed down. The last really great discovery was that of Schaudinn of the *Spirochæta pallida* in 1904 which, incidentally, is of course not a bacillus. It is true that there was a separate and later burst of advance in connexion more especially with tropical diseases and the recognition of increasing numbers and species of pathogenic protozoa. But admitting this, how very little apparent advance, or shall I say how very little sensational advance, there has been either in bacteriology or immunology in the last 20 years, say from 1905 to 1925!

This does not mean that during these 20 years there has been any reduction in the number of eager workers and investigators. On the contrary, the number has vastly increased. Think also how vast has been the improvement, both in the number of laboratories and in bacteriological technique during the same period. Think also of the improvement in the standard of laboratory work demanded of the students. It is not, I feel confident, that there were giants between the 'seventies and 'nineties who to-day are non-existent. Nothing of the sort. It is merely that here we have yet another instance of the nature of man's progress, another instance supporting my old friend the late Prof. Bateson's contention that evolution is not by imperceptible, gradual and minute advances, but is by sudden leaps and bounds, followed by long periods with little or no obvious change. It is akin to what time and again we notice in other human activities. Within 20 or 30 years of the introduction of Norman architecture we find built the most superb examples of that style, and for a hundred years or so there is no sensible advance; then Pointed architecture comes in, and again in less than a generation the style is perfected, and so with the Decorated and the Perpendicular styles. Within a generation of the invention of the printing press were produced absolutely the finest examples of printing as regards artistry and clearness of type, perfection of paper, and appearance of the printed page, and that not in one place but in many. Since then we may have developed the mechanical devices of the printing press, the linotype and other methods of composing the page; we may turn out in five minutes more 24-page newspapers than the old time printer could have printed in the year; but for quality and beauty of bookwork the climax was reached close upon 500 years ago, in less than a generation. We celebrated last year the centenary of the railway locomotive—we are to celebrate shortly the centenary of the opening of the Liverpool and Manchester line. By 1840 railway engines were being produced as speedy as any to-day, or as speedy within very few miles per hour. We have improved the haulage power, and have increased efficiency and fuel economy, but to all intents and purposes, by the activities of a vast number of keen engineers testing out this and that, the steam engine was largely perfected within 15 years of the opening of the first railway. After that advance slowed down so as to appear to the onlooker almost to cease, though engineers will tell you of constant attempts at further improvement. The same story seems to be that of the present generation in regard to gas and oil motors, and to be in the process of fulfilment as regards aeroplanes. Underlving and inducing each burst of advance is clearly the discovery of some new technical device of easy general application; in architecture, I take it, the formula for the construction of semicircular, pointed and ogival or two-centred arches respectively: in printing the use of movable type; in mechanical locomotion the invention of a not too cumbrous steam engine; in the motor-car and aeroplane the invention of yet lighter engines, driven not by steam but by the explosion of gases; in bacteriology, in the first stage, the improvement of the microscope, in the second effective stage Koch's application of the botanical method of gaining pure cultures upon solid media, and Ehrlich's utilisation of aniline dyes to stain bacteria. Or, put otherwise, for human advance it is not so much the act of invention or discovery that counts as it is the demonstration of methods of utilisation of the invention or discovery, which are so simple and straightforward that all interested can apply them and confirm their value, and doing this can, by the method of multiple trying out and modification, bring them rapidly to relative perfection. Though always the greatest man of science, the genius of the first water, is he who combines the discovery of a principle with development of a simple means of confirming and applying the principle.

### KOCH AND THE BACILLUS TUBERCULOSIS.

Now what is true of the general is true also of the particular. The discovery by Robert Koch of the *Bacillus tuberculosis* and of the means of growing it in pure culture, followed as it was rapidly by the elaboration of means of easy diagnosis, of which the use of fuchsin and the Ziehl-Neelsen stain deserve especial mention, placed our knowledge of the disease upon a wholly different footing. It made it possible for a man like Trudeau, isolated in the wilds of the Adirondacks, with some knowledge of the microscope but no previous training in bacteriology, within a few months not merely to recognise the bacillus but to obtain pure growths, and with these to convey the disease to animals of the laboratory. It gave the death-blow to the prevalent doctrine of diathesis. It showed us that consumption, tabes mesenterica, lupus, white swelling of the knee, spina ventosa, and many other conditions, including pearl disease of the lungs of cattle, were different manifestations of one common disease affecting different tissues and different species. It increased vastly the boundaries of our knowledge and above all it provided us with a sure means of diagnosis. Koch himself, in the years that preceded the publication of his great paper in the *Mittheilungen* of the Kaiserliches Gesundheitsamt, with vast industry demonstrated most of these facts, to have them rapidly confirmed in all parts of the world. It was a marvellous advance in our understanding of one of the great plagues of social life, and for this great investigation and discovery alone Koch must stand out as one of the greatest masters of medicine throughout the ages.

Undoubtedly to Koch and his discovery we owe the campaign against tuberculosis and its spread throughout the civilised world, the abundant provision of hospitals, sanatoria, dispensaries, and district nurses, and all the many means now employed both for the prevention and the cure of the disease, up to the latest provision of artificial sunlight and ultra-violet ray treatment. Yet how very slightly—save in the matter of diagnosis—this bears a direct association to Koch's discovery, how very little the methods we now employ both for prevention and cure have to deal with bacterio-therapy, how largely they are extensions and expansions of methods in vogue long years before Koch's discovery. Bodington introduced the open-air treatment a generation and more before the 'eighties. The treatment of pulmonary consumption by pneumothorax and lung collapse was first attempted here in Liverpool by Dr. James Carson in 1822. Just as in this country in the middle ages leprosy was stamped out without any scientific knowledge of the laws of infection, by segregating those afflicted with the disease in leper hospitals, so, as I heard Koch himself acknowledge at the London International Tuberculosis Congress in 1902 (was it not?) the reduction in tuberculosis mortality, in which this country led the world, dates from the Poor-law legislation of 1834, the establishment of workhouse infirmaries and the segregation of bed-ridden consumptives in the same. Without knowing what they were accomplishing, the Poor-law authorities in this way weeded out from the crowded houses of the poor the open infective cases of tuberculosis, thereby materially decreasing the opportunities for massive infection with the human strain and steadily reducing its ravages. The remarkable fact, as pointed out recently, is that from the 'fifties onward the reduction in tuberculosis mortality in this country pursues a relatively straight descending line, with no abrupt fall or increasing descent following upon Koch's discovery in the 'eighties.

### *Disappointed Hopes.*

In other words, great as was the advance in diagnosis brought about by Koch's discovery, it was not followed by a corresponding advance in treatment directly dependent upon it. Those of us who, like myself, date their entrance into medicine from the spacious days of the 'eighties, will remember full well what hope we then had, not to say what confidence filled us. Pasteur was producing his vaccines, Behring and Roux their antitoxins and sera. Once the bacillus of tuberculosis was found, it seemed sure that very soon we should possess either a means of vaccinating against the disease or, still better, some bacterio-therapeutical means of arrest and cure. Forty years and more have elapsed, and despite immense and unremitting efforts in laboratories scattered all over the world only now are we beginning to see light and entering upon the next great period of advance. For this I feel confidently to be the case. And this delay, let me once again emphasise, has not been from any lack of application or lack of genius, but purely from the difficulties of the problem. Koch himself, you remember, tried and failed—failed ignominiously. What hopes were raised when, in 1880, he announced his tuberculin; and with what tragic rapidity they evaporated into thin air.

It may be well to recall here the various lines of attack that have been tried and found wanting. Pasteur and his co workers had shown that in general the most powerful and long continued immunity was conferred by the natural disease—i.e., by the activity of pathogenic organisms of normal virulence under such favourable and fortuitous conditions that death did not ensue. Immunity, but apparently of lessened duration and effectiveness, could be gained by attenuating or lowering the virulence of the germ or vaccination proper, and, lastly, by inoculating either the dead bacilli or their products, the soluble poisons produced in the medium of growth outside the body either as active excretions—ectotoxins—or as disintegration products liberated on the death of the bacilli—endotoxins. Very soon it was discovered that there was an extraordinary variation in the mode of reaction of the organism to the different pathogenic microbes and the grade of immunity induced. The tubercle bacillus was evidently totally different from, for example, the diphtheria and tetanus bacilli on the one hand, the typhoid and cholera bacilli on the other. Inoculation either of the dead bacilli or of their products have been almost equally unsuccessful. The most we can say is that they possess a slight preventive capacity and confer a moderate grade of increased resistance which, however, rapidly passes off. As you know, I could spend an hour detailing the many most ingenious modifications of Koch's original tuberculin and derivatives of the bodies of the tubercle bacilli which have been tested, down to Dreyer's Oxford diaplyte vaccine, and what I may term the sensitised vaccine of Rappin of Nantes, the one obtained by treating the virulent bacilli with formalin and acetone (to remove the fatty substances) the other obtained by acting on the dried bacilli with fluoride of sodium and adding these to serum of oxen subjected to inoculation with the same bacilli.

There is a like history of the attempts to confer immunity by the employment of attenuated strains of the tubercle bacillus. I may remind you that for long years Koch and the Germans strongly upheld the unitarian view of the existence of one type or strain of tubercle bacilli common to all species. Only at the London Congress already referred to did Koch dramatically announce his conversion to the contrary view and announce it as his own discovery, heedless of the previous work of Straus and Grancher in France regarding the specificity of avian tuberculosis, and of Theobald Smith and Dinwiddie in the United States concerning the distinctiveness of the bovine tubercle bacillus. As early as 1880 Grancher and Ledoux, basing themselves on the fact that the avian bacillus is not pathogenic for man, endeavoured without success to utilise the avian strain as a vaccine for human beings. After Koch's pronouncement Behring, in 1902, appeared to have more success in employing emulsions of living human tubercle bacilli to immunise calves against the bovine disease by intravenous inoculation. But while these inoculations did not, it is true, set up tuberculosis, neither did they induce other than a very transient immunity, and, as Stanley Griffith pointed out in 1918, Behring's method of *Jennerisation* had a distinct danger for man, for the human bacilli might be discharged in the milk and so infect the cowsheds and those consuming the milk.

Equal lack of success has followed the attempt made by many to vaccinate human beings with the bovine strain, whether virulent or attenuated, and with the yet more attenuated, non tubercle producing strains of tubercle bacilli derived from cold-blooded animals like carp and other freshwater fish and tortoises. Personally, I remember vividly the excitement set up by Friedmann and his "turtle" bacillus. When Friedmann came from Berlin to the States I happened to be President of the Montreal Medico-Chirurgical Society. The profession in the United States turned their backs upon him because, instead of distributing his vaccine to all and sundry, he demanded that for the time he alone should administer it. He had, nevertheless, demonstrated his method before accredited societies in Germany and was a qualified physician, added to which he had clearly described the nature of his vaccine, and there was no reasonable doubt that it was as he described it, an emulsion of tubercle bacilli derived from a tortoise or turtle. Rather than make a martyr of him in the eyes of ordinary people, it seemed to the Council of our Society a more politic course to pursue to offer him to select 20 cases from among those willing to undergo his treatment, and to let him treat these on the one condition that, following upon the treatment, the cases should be under the supervision of tuberculosis experts chosen by the Society, who should report upon the progress of the same. I may add that two or three showed *definite* but temporary improvement, the remainder were unaffected or rendered worse rather than better. The method was obviously inadequate, and the test by no means fulfilled what was claimed by Dr Friedmann.

It is, I would urge, along these lines that we as a profession should deal with the Spahlinger treatment. Very many of the laity, and some of our profession, are convinced that Spahlinger is both a genius and an absolutely honest man. Do not let us, as a profession, make a martyr of him by refusing to have anything to do with him or his treatment, but on the contrary let us give him full opportunity to prove his contentions by asking him to treat cases selected by himself from a group fully diagnosed, and this under the supervision of well-known experts and under conditions agreed to by both sides as being beyond criticism.

Nevertheless, the studies of the last 45 years have elicited certain indications bearing upon immunity in tuberculosis and showing that it is within the boundaries of the possible. The first of these is that, whereas careful post-mortem examination, confirmed by intradermal and other tuberculin tests, show that at least 90 per cent. of the population at one time or another have been the subjects of tuberculosis, the deaths from this disease are only from about 10 per 10,000 of the population, the total death-rate from all causes being over 130 per 10,000. In other words, tuberculosis is one of the most curable of diseases and the majority of us have developed immunity. The next is that if, as happened during the war, men from the tropics, from regions where tuberculosis is practically non-existent, are brought to Europe, they rapidly succumb to tuberculosis in large numbers. This may well be interpreted as meaning that one attack of tuberculosis that has been recovered from in youth very largely protects against a later attack, an interpretation confirmed by the common observation that those suffering from lupus or from tuberculous glands rarely exhibit signs of pulmonary consumption; or put otherwise, if 90 per cent. have been infected at one or other time, only 7·5 per cent. of all deaths are from this disease. And these observations are on a par with what Calmette denominates "Koch's phenomenon." It was Koch's observation that tuberculous guinea-pigs react to subcutaneous inoculation of tubercle bacilli in a manner quite distinct from the reaction of healthy guinea-pigs. There is a similar difference when in place of living bacilli dead bacilli or bacillary products are introduced subcutaneously, and this is the basis of the intradermal and other cutaneous methods of diagnosis.

### CALMETTE'S RECENT WORK.

And thus I come finally to what I believe is the great advance of to-day—an advance equally important for the prevention of both human and bovine tuberculosis. I refer to the great work of my old friend Prof. A. Calmette, at one time professor in the University of Lille, and then one of the sous-directeurs under M. Roux, but now Directeur of the Institut Pasteur in Paris. I have not hesitated to follow during the last few minutes his development of the subject as given in his latest paper in the February number of the *Annales de l'Institut Pasteur*. From his long years of study of experimental tuberculosis, Calmette concludes on the one hand that a light infection with tuberculosis in infancy is not undesirable, since it confers upon the organism a sufficient power of resistance to protect against later reinfections, provided they are not massive, and certainly protects against a rapidly advancing miliary tuberculosis. On the other hand, he concludes that it is neither practicable nor possible to vaccinate adults who are already infected, and this because of the risk of provoking Koch's phenomenon which he regards as a "phenomenon of intolerance," to this extent, that the reaction it produces in old tuberculous lesions leads too often to caseation and softening and discharge of virulent germs from these foci into the circulation, and so, in some individuals, to a lighting up of what had been a relatively quiescent tuberculosis. He thus concludes that in a heavily infected country—for example, in Europe and the United States—antituberculosis vaccination is only possible among the newly born, or at most in quite young children or animals which from birth have been protected against infection.

For this purpose, after years of work he has found that growing virulent tubercle bacilli in glycerinated ox-bile, an alkaline medium rich in lipoids, and transferring to new medium every fortnight, in four years the cultures become no longer virulent either for cattle or guinea-pigs, although still virulent for the horse and rabbit. After 230 cultures in 13 years the cultures became harmless for all domestic animals. At most, a strong dose inoculated under the skin of a guinea-pig set up a cold abscess which underwent cicatrisation, leaving, it might be, a slight induration. There was no enlargement of the nearby glands.

It is this attenuated bacillus B. C.-G., or *Bacillus Calmette-Guérin*, that he uses for his vaccinations of both calves and new-born infants. Inoculated into various animals it has shown no return of virulence. And abundant experiments have shown that using it young animals not suffering from any pre-existing tuberculosis have the same resistance to tuberculous infection of later acquirement as have animals lightly affected by what may be termed a benign bacillary infection, latent or occult.

But now, upon examining the lymph glands of the animals inoculated with B. C.-G., Calmette finds that, although no tubercles are formed, the bacilli remain alive, it may be, for several months. He compares this condition with what we find in syphilitic tissues, in glanders and probably in leprosy. To distinguish from ordinary vaccination, in which we presume that the inoculated bacteria are rapidly destroyed, Calmette terms this particular form *premunition*. This long continuance within the tissues, without of necessity setting up active lesions, is not unlike what we find in syphilis. There the spirochætes may be present for years without causing gummata, and there also, so long as living spirochætes are in the system, the bearer is immune against reinfection with the disease.

If, therefore, argued Calmette, the human being or animal already infected with a mild or benign type of tuberculosis, such as lupus or caseous lymph glands, is protected against reinfection, though not protected against the possibility of the disease lighting up again from the existing foci, should the general resistance be greatly lowered, a yet more attenuated strain of bacilli may have the same protective effects without danger of subsequent lighting up of the active typical disease. And if the protection only lasts so long as the bacilli remain alive within the tissues, it can be maintained by reinoculation.

#### *Results of the B. C.-G. Treatment.*

And next he proceeded to test if this were so. He found that whereas rabbits 4 to 5 lb. in weight when inoculated with 1/1000 mg. of a culture of typical bovine tubercle bacilli died from the disease in 50 to 65 days, similar animals showed no tuberculosis when similarly inoculated, if, previously, they had been given intravenously a dose of 25 to 30 mg. of a culture of B. C.-G. made into an emulsion. And in young rabbits 15 to 20 days old a similar protection could be conferred by feeding B. C.-G. by the mouth—five to ten doses of 20 mg. of B. C.-G. repeated five to ten times. And the protection so conferred lasted at least six months. There is abundant evidence that in the newly born, bacilli pass with ease through the gastric and intestinal mucous membrane into the system.

Coming nearer to man, Wilbert, one of Calmette's collaborators, made an extensive test in French Guinea upon 15 chimpanzees and 50 pithecus monkeys. He found that inoculation or ingestion of up to 100 mg. of B. C.-G. cultures were equally without harmful effect in both species; at most there was some slight and temporary swelling of the lymph glands. The premunition conferred by suitable doses lasted at least a year; it could be continued by a repetition of the inoculations or ingestions at the end of the year, and animals so treated could live in habitual contact with other chimpanzees and monkeys infected with open tuberculosis without showing a sign of the disease. After two years of such cohabitation the animals remain uninfected. The method has been tested extensively upon cattle since September, 1924. Up to Jan. 1st, 1926, over 3000 calves had been inoculated in France, Germany, Holland, and Belgium.

The features of the treatment have been as follows. New-born calves, and new-born calves only, have been treated by a single inoculation into the loose tissue of the dewlap of 50 to 100 mg. of B. C.-G., the inoculation being repeated at the end of 12 months. Thus far not a single case has been reported of harmful effects. It must, however, be borne in mind that animals so treated are apt to give the tuberculin reaction. On the other hand, it is evident that here is provided a means whereby in a country whose cattle are heavily infected with tuberculosis, without changing the usual methods of dealing with the cattle or of bringing up the calves, tuberculosis may be eradicated from herds. All that is necessary is to vaccinate the calves with B. C.-G. during the first 15 days of their existence, and to revaccinate them in a year's time.

And now let us turn to man. It was Behring, if I mistake not, who first laid down emphatically that infection with tuberculosis in most cases dates from early childhood. This view Calmette espouses, and he gives striking figures. Combining the figures yielded by Paris, Vienna, Dresden, Breslau, Prague, and Stockholm, he shows that on the average 19·8 out of every 100 deaths of infants under 12 months old are from tuberculosis. After one year the mortality from this cause rapidly decreases. Thus in Prussia, for every 10,000 of the population the tuberculosis mortality is 24·02 for the first year, 17·01 for the second year of life, and 4·0 for the ages 5 to 15. A return made by the tuberculosis dispensaries in 80 French departments gives corresponding figures. 1302 tuberculous women were found to have given birth in 1922 to 1304 children (two had twins). Of these 1304 children, 327 were stated to have died of tuberculosis in their first year, or 24 per cent. The figures for Paris alone give the yet higher figure of 32·6 per cent. In Belgium, in the dispensaries of the National League, despite the attentions of the visiting nurses of the League, among the infants of tuberculous mothers, brought up by those mothers, the mortality in the first year is 20 per cent. These continental figures, it must be admitted, are greatly in excess of those of most British cities. In Liverpool, for example, in the last year of which we have record —1924—of 2118 deaths under one year only 34 were from tuberculous disease, or 1·6 in place of Calmette's 19·8 per cent. Still, it must be remembered that Calmette's figures are culled from tuberculosis dispensaries and other institutions which deal mainly with children of tuberculous parentage, and as Lissant Cox and MacNalty have pointed out, in one London tuberculosis dispensary the tuberculosis mortality among the children under 1 year was 22 per cent.

Since 1921, when Dr. Weill-Hallé began the work upon infants born in the maternity department of the Charité Hospital in Paris, the use of B. C.-G. for the vaccination of the new born has rapidly developed. In 1922, 217 new born were subjected to a course of these preventive ingestions of 1 cg. of B. C.-G. cultures. From July 1st, 1924, to Jan. 1st, 1926, 5182 infants were similarly vaccinated by the mouth in Paris and throughout France. Of these 5000 odd, 1817 have been individually reported upon for periods varying from 6 to 18 months. Of these 1317, there were 564 with premunition extending from a year to 18 months, 753 with premunition extending from six months to one year.

Take first the 564 cases of longer continuance. Only two died of presumed tuberculosis, 48 of disease of other nature, and this despite the fact that 281 were reared in contact with tuberculous parents or others suffering from the disease.

Of the 753 of shorter continuance, nine died of presumed tuberculosis, 53 from other conditions. Even if all the deaths had been from tuberculosis, the percentage mortality would have been only 8·2 instead of the usual Parisian percentage of 20 and more, and this although no less than 355 had been raised in habitual contact with infected persons. If we add together all the cases, out of 1317 infants vaccinated six months and more, only 0·7 per cent. had died of conditions diagnosed as tuberculous. I would ask you to compare this figure with the minimum mortality of 25 per cent. recorded for the tuberculosis dispensaries of France in general and the 32·6 per cent. of Paris.

Here, obviously, is a magnificent advance. As regards the few deaths from tuberculosis of infants subjected to this method of vaccination by the mouth, or premunition, it must be recalled that the existence is admitted of a small proportion of infants infected in utero. Further, it may well happen in the circumstances that another small proportion of infants become subject to massive infection by the human tubercle bacilli before the premunition becomes effective.

Possibly, I owe an apology for entering into such full detail regarding methods and results already well known to many of my audience. Occupied as I am with university administration, I acknowledge and bewail the fact that it is not possible for me to keep up my reading in all branches of medicine. At most I have been able to read regularly THE LANCET and the *British Medical Journal*. Thus I may easily have overlooked a wide British literature upon Calmette's work. Yet what has impressed me has been that in the above-mentioned organs in which matters of foremost interest to the profession are discussed, there has been altogether inadequate recognition of what I regard as the greatest and most notable advance in the arrest of tuberculosis accomplished in our generation. It is true that it is preventive and not curative. But it is the culmination of a series of investigations by one man and his collaborators carried on steadily since 1906. It is an admirable example of my to-day's thesis regarding advance in general—namely, that for long years work of the first order may be pursued, which for all those long years may well seem to the outside world, and even to our profession, to be purely academic, and devoid of interest save to the man of science, but which nevertheless leads eventually to some simple generalisation capable of confirmation the world over, not by the expert alone, but by the ordinary practitioner, which then at a bound becomes the guiding principle of a new era.

For if this principle of Calmette be grasped, then we see before us a simple means of eradicating both human and bovine tuberculosis. To give a dose by the mouth of an emulsion of B.C.G., to the newly born infant, and again to the child of 1 year and of 2, sets up no disturbance but carries that child over the period of most frequent infection with the active disease. The same is true of the calf. We still have to learn how far the premunition confers a more and more lasting immunity the more often it is repeated, to learn whether it resembles ordinary vaccination in this respect. This, however, appears to be indicated most definitely, that all children born into tuberculous households should be given this treatment. And it may well be that this should become the routine treatment for all children, as much a routine as vaccination proper.

# HOUR-GLASS STOMACH:

## THE OPERATION OF CHOICE.

BY SETON PRINGLE, F.R.C.S. IREL.,
SURGEON TO THE ROYAL CITY OF DUBLIN HOSPITAL.

THE surgery of the stomach presents no more interesting problem than the treatment of hour-glass contraction; the conditions found at operation are so various that no one method can meet all cases, and often the judgment and ingenuity of the surgeon are taxed to the utmost.

I have employed many different procedures, and in many cases have had the results controlled by post-operative X ray examinations. Some methods I have discarded as unsatisfactory; others I have found successful in varying degrees, and so have gradually formed a fairly definite opinion as to their relative merits. Perhaps it may be of service and interest to others to follow the steps by which I arrived at this opinion, and to enable them to do so I will quote some cases illustrative of the methods employed, with in most cases pre- and post-operative X ray photographs.

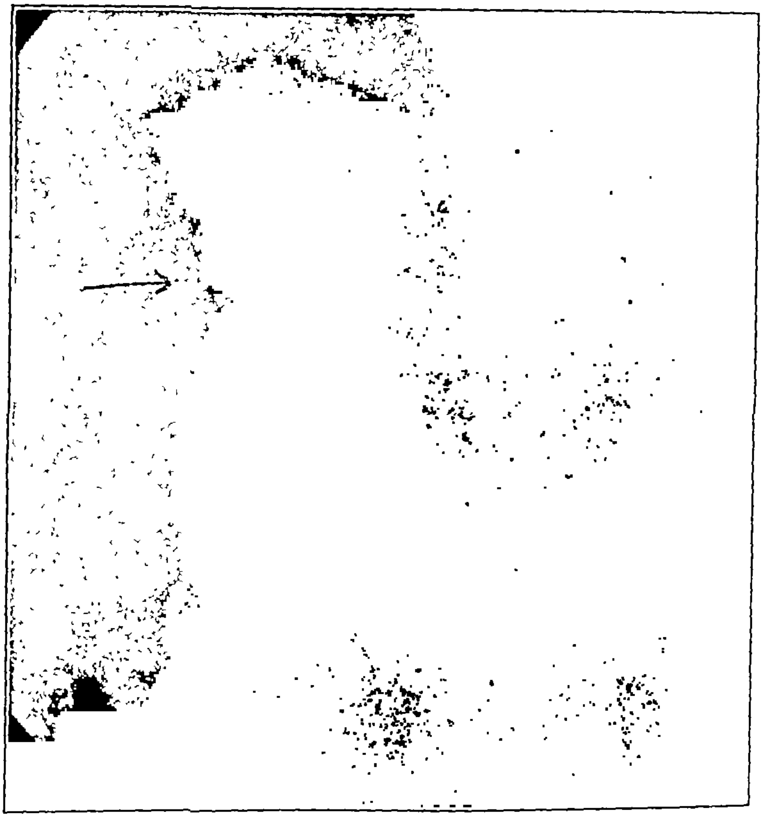
### *Diagnosis of Hour-Glass Stomach.*

Before doing so I would like to refer shortly to the diagnosis of the condition. About 80 per cent. of the cases occur in females and all, without exception, give a history of gastric trouble extending over many years. Most cases present the symptoms of pyloric obstruction, with or without the addition of active ulceration. Vomiting is the most marked and constant feature; the vomiting is, however, not usually of such a large quantity, and occurs at more frequent intervals than in pyloric stenosis. Pain comes on at varying intervals, from a few minutes to perhaps an hour after food, and is relieved by vomiting. As a rule there is nothing characteristic in the nature of the pain, but a few of my patients complained of a "squeezing" or "griping" pain in the left hypochondrium, and I consider that pain of this character is of value in suggesting a diagnosis.

Physical examination as a rule helps but little, but the failure to discover a dilated stomach in a suspected case of pyloric stenosis should arouse suspicion. The diagnosis really rests on the result of the X ray examination after a barium meal, and in this connexion there are two points to which I should like to call attention. First, there is frequently found a marked six-hour residue in the distal sac, even when there is no pyloric or duodenal obstruction, and this I take to be partly due to the delay in the delivery of the meal through the constriction, and partly to the fibrous ring of the constriction interfering with the normal peristalsis of the stomach. In the second place, the X ray plate, when taken with the patient standing up, invariably shows the constriction lying at a much lower level—and hence more accessible—than is found to be the case at the subsequent operation. The stricture also appears to be longer and narrower than is actually found with the patient lying on the operating table with the stomach empty. I believe that the weight of the barium distorts these stomachs, which are often atonic and thus the plate taken with the patient in the erect position tends to give an exaggerated and somewhat misleading picture of the actual condition present.

hour-glass constriction with very large distal sac; no pyloric stenosis. Operation: Cautery excision of ulcer; posterior gastro-enterostomy across constriction, the stoma extending

FIG. 2 (Case 2).

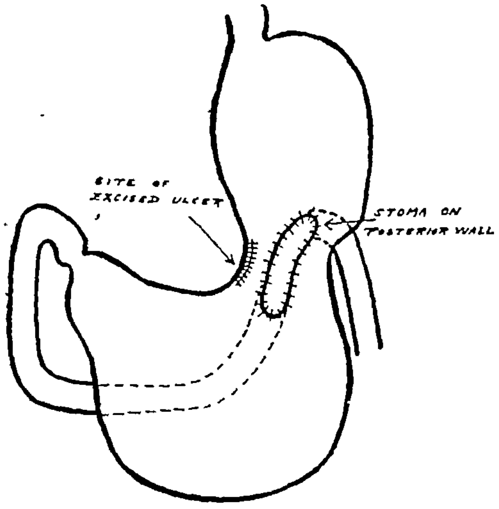


Post-operative X ray. Four weeks after a gastro-gastrostomy by adaptation of Finney's gastro-duodenostomy. Note persistence of constriction.

### *Methods Employed: Illustrative Cases.*

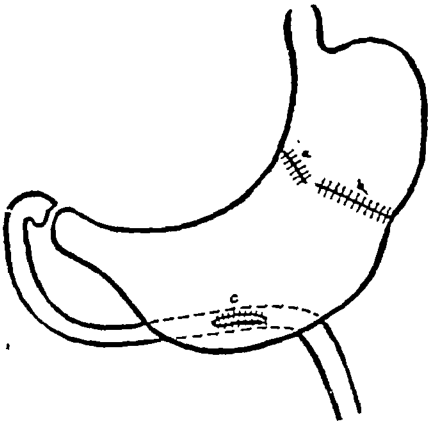
CASE 1. *Posterior gastro-enterostomy across the constriction and extending into both sacs with excision of ulcer.*—J. M., aged 38. Fifteen years' history of pain after food and vomiting. X ray: Well-marked constriction at junction of upper and middle thirds; ulcer crater on lesser curvature; constriction probably partly spasmodic. Operative findings: Active ulcer on lesser curvature; scars of several healed ulcers on posterior wall at same level; marked into both sacs (Fig. 1). Remark: An attempt to provide an outlet from both sacs by means of one large stoma, instead of by a separate stoma into each sac. Result: Patient relieved of pain but suffered from discomfort and vomited occasionally. Post-operative X ray: No evidence of con-

FIG. 1 (Case 1).



Posterior gastro-enterostomy across constriction, followed by marked retention of food in dilated distal portion of stomach.

FIG. 3 (Case 3).



Diagrammatic representation of condition at conclusion of operation showing (*a*) site of excised ulcer, (*b*) suture line after Finney's operation on constriction, (*c*) posterior gastro-enterostomy into distal sac.

striction; barium passing rapidly through stoma; large six hour residue in part of stomach corresponding to distal sac. Note: Apparently a considerable portion of the food passed over the highly placed stoma into the dilated atonic distal portion of the stomach and marked delay occurred there, even in the absence of pyloric stenosis giving rise to persistent discomfort and occasional vomiting. The result in a similar case in which the same operation was performed was also unsatisfactory and consequently, the method was discarded.

FIG 4 (Case 4)

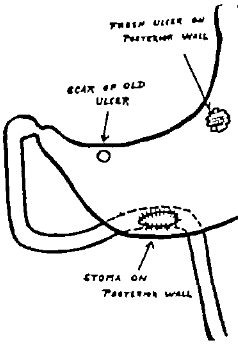


Diagram to show condition found at second operation.

FIG 5 (Case 4)

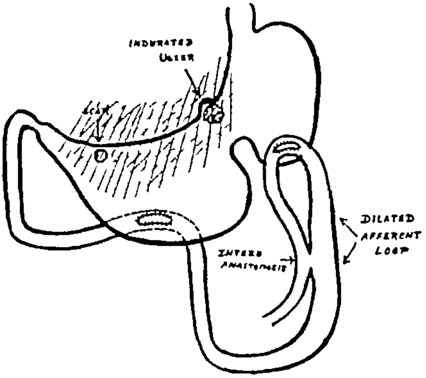

Diagram of final condition showing anterior gastro-enterostomy into proximal sac and entero-anastomosis

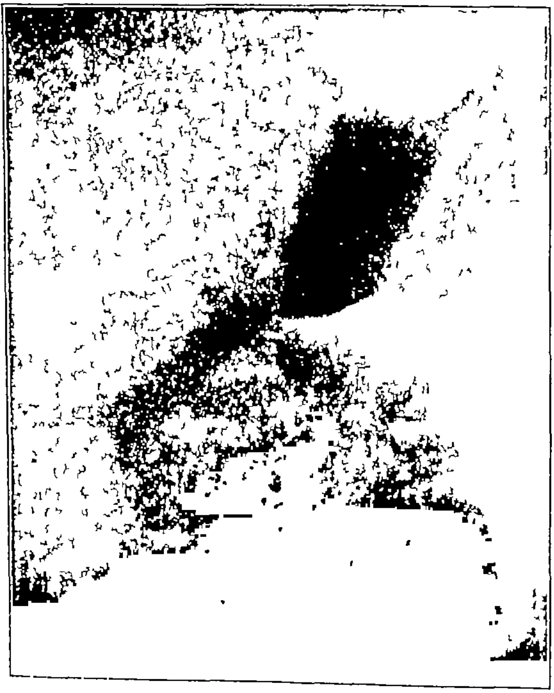
CASE 2 *Finney's pyloroplasty on constriction with excision of ulcer*—Mrs. S., aged 45 History of many years trouble X ray: Ulcer demonstrated high up in the lesser curvature with very marked constriction. Operation: Ulcer excised and the two sacs united by operation similar to Finney's gastro-duodenostomy Result: This patient made a very satisfactory recovery but an X ray four weeks after operation showed well-marked constriction still present (Fig. 2) Unfortunately, she cannot now be traced.

CASE 3. *Finney's pyloroplasty on constriction with excision of ulcer and gastro-enterostomy*—Miss X, aged 52 History: Extending over 30 years. X ray: Very marked constriction demonstrated high up in stomach, with marked retention in both sacs. Operation: Ulcer at site of constriction excised and the two sacs united by the method of Finney's gastro-duodenostomy; posterior gastro-enterostomy into the large lower sac as stricture of the pylorus was also present (Fig. 3). Result: Symptoms were quite relieved and have remained so up to the time of her last visit some nine months later, although an X ray at that time showed a considerable amount of constriction, with the stoma from the distal sac functioning normally Note: The *immediate* post-operative appearances in this and in Case 2 were excellent the stomach appearing normal in shape and contour but subsequent examination in these two cases demonstrated the liability to recurrence and therefore, I have discarded this method also.

CASE 4 *Anterior gastro-enterostomy into upper sac combined with entero-anastomosis at a later date*—Miss G, aged 28 First operation: In 1914 I excised an ulcer in the anterior

FIG 6 (Case 6)



X ray 18 months after operation. Rapid emptying of barium through anastom proximal sac to the duodenum after a partial gastrectomy wall near the pylorus and did a posterior gastro-enterostomy. Patient returned in 1921 with recurrence of symptoms. As teeth were very foul these were extracted and the abdomen opened a month later. Second operation: I found an indurated ulcer the size of half-a-crown on the posterior wall of the stomach, *above* the site of the gastro-enterostomy and densely adherent to the pancreas (Fig. 4). I carried out a transgastric excision of the ulcer. Result: Patient had complete relief for almost a year. Symptoms then recurred and an X ray showed a well-marked constriction in the pars media with the stoma from the distal sac functioning normally. Third operation: At the subsequent operation I found the pyloric half of the stomach buried in dense adhesions, in the centre of which an indurated ulcer could be felt. An anterior antecolic gastro-enterostomy with a long loop was performed into the upper sac. Following this she had relief from pain but vomited at frequent intervals. An X ray six weeks later showed the food passing through this new stoma into a greatly distended coil of the small intestine, which the radiologist considered to be the efferent loop. Fourth operation: On opening the abdomen for the fourth time I found that the *afferent* loop of the anterior anastomosis was greatly dilated and hypertrophied. Anastomosis was then performed between the afferent and efferent loops, and this provided complete relief (Fig. 5). Note: The occurrence in this case of fresh ulceration above the site of a functioning gastro-enterostomy is of interest.

Case 5. *Posterior gastro-enterostomy into proximal sac.*—Miss A., aged 50. History: Perforated gastric ulcer 22 years ago; two operations in interval by other surgeons—namely, resection of the hour-glass constriction, and division of adhesions, both of which operations relieved for several years; recurrence of symptoms for past year. X ray: Well-marked cicatricial hour-glass with a considerable six-hour retention in both proximal and distal sacs. Operation: Pyloric half of stomach buried in dense adhesions, among which could be felt an indurated ulcer adherent to liver; no attempt made to separate; posterior gastro-enterostomy into upper sac. Result (18 months later): No discomfort, pain, or vomiting; has put on weight. X ray: Proximal sac empties rapidly through stoma—distal sac not demonstrated.

Case 6. *Excision of distal sac.*—Miss H., aged 38. History: Gastric trouble for seven years. X ray: Marked constriction in mobile ptotic stomach. Operation: Excision of distal sac with anastomosis of stomach to stump of duodenum—i.e., partial gastrectomy by method of Bilroth 1. Result (18 months later): Patient reported herself as being "splendid and able to eat anything." X ray: Stomach emptying rapidly through new opening (Fig. 6). Note: In other cases the remaining portion of stomach has been anastomosed to jejunum—i.e., partial gastrectomy after method of Polya 2, and in all cases immediate and after-results have been excellent.

### *Unsatisfactory Methods of Treatment.*

It will be noted that I have not made use of two methods which have been advocated for the treatment of hour-glass stomach—excision of the stricture with resulting end-to-end anastomosis—i.e., the so-called "sleeve" resection, or the method of gastro-gastrostomy by simple anastomsis between the two sacs. With regard to the first, the results as reported by other surgeons are not sufficiently satisfactory to encourage me to try it on any of my earlier cases and, later on, it seemed to me that the cases on which it could be employed were just those in which partial gastrectomy was indicated, and that, while the operation was quite as severe, the results were less likely to be satisfactory. One of the cases reported above (Case 5) had already had a sleeve resection done by another surgeon. As regards simple gastro-gastrostomy, I considered that the adaptation of Finney's pyloroplasty to the constriction gave a better anatomical and mechanical result, and since the latter has proved unsatisfactory, I saw no reason to hope that the former would be more successful.

### *Conclusions.*

The conclusions at which I have arrived as the result of my experience controlled by X rays are: 1. Partial gastrectomy is the operation of choice whenever possible, and the percentage of cases in which it is possible rapidly increases with experience. 2. When gastrectomy is not feasible owing to adhesions around the distal sac, or to the high position and small size of the upper sac, I believe a posterior gastro-enterostomy into the upper sac is the best procedure. 3. When the distal sac is large or obstruction of the pylorus or duodenum also exists, a second stoma should be provided from the distal sac into the same or another loop of jejunum. In cases of difficulty I have no hesitation in performing an anterior gastro-enterostomy with, or without, an entero-anastomosis. 4. I regard as unsatisfactory all direct attacks on the constriction either by means of a single gastro-enterostomy across the constriction (the opening extending into both sacs) or by any plastic operation such as Finney described for stricture of the pylorus.

## A NOTE ON THE CAUSATION OF GYNÆCOMASTIA (MAMMARY FEMINISM).

By F. PARKES WEBER, M.D. Camb.,
F.R.C.P. Lond.,
PHYSICIAN TO THE GERMAN HOSPITAL, LONDON.

Gynæcomastia—or as one might term it, "mammary feminism"—is the condition of enlargement of the breast in a male causing the organ in question to appear like that of a female; this condition may be bilateral or unilateral. The *bilateral* form may, in some cases, be "primary" or "essential"—that is to say, really of unknown developmental causation; in fact, it may be a localised "mammary form of feminism," unaccompanied by any other signs of feminism; but in other cases (usually accompanied by various obvious bodily, and possibly psychical, signs of feminism) it is definitely of endocrine origin, and secondary to deficiency of the testicular interstitial gland. Castration may be a cause of gynæcomastia, if performed during the period of early sexual activity; or the deficiency of the interstitial gland may be due to congenital or acquired disease, such as, for instance, testicular atrophy caused by the orchitis of mumps. It can hardly be caused by gonorrhœal or tuberculous epididymitis, because in such cases the interstitial gland of the body of the testis is not destroyed. It need not invariably accompany conditions of male sterility, for the seminal functions of the testis may be destroyed without destruction of the interstitial gland. If the testes are excised, destroyed, or injured some years after the establishment of puberty, gynæcomastia may be the only (or at least the chief) result in regard to alteration in secondary sexual characters. So far I am in accordance with the conclusions of J. Decléty and others (see below).

The occurrence of *unilateral* gynæcomastia can obviously not be explained in the same way any more than could unilateral acromegaly (if, as has been claimed, there really were such a condition)[1] be attributed to an endocrine disturbance of pituitary (hypophyseal) origin. Certain cases of unilateral gynæcomastia have followed injury to the testis of the same (or still more rarely of the opposite) side,[2] and Decléty[3] points out that in such cases the injury to the testis was received during the period of full sexual development, not before the onset of puberty. Decléty believes that the cases in question can be explained on the supposition that in males the normally active testis, apart from its hormonic (endocrine) effects, exercises a reflex nervous inhibitory action on the growth of the breast, which would otherwise in normal males about the period of puberty tend to develop as the female breast does under the influence of the hormones of puberty; a traumatism, even of slight degree, to one testis may, he suggests, remove this inhibitory action.

Here I would also refer to Condomine's case[4] in which *bilateral* gynæcomastia followed severe injury to *both* testes in a young soldier aged 21 years.

Decléty[5] goes even so far as to suggest that cases of unilateral gynæcomastia are *always* due to a congenital or acquired testicular lesion, especially a testicular traumatism (usually of the same side as the gynæcomastia, rarely of the opposite side). It seems difficult to accept this conclusion in view of the cases of unilateral gynæcomastia that have been published by various observers without reference to any lesion or traumatism to either testis.

The accompanying portrait (see figure) is that of a man, aged 34 years, whom I saw in 1898, with unilateral gynæcomastia of the right side I saw him again in 1901, on account of some bronchitic trouble, and I noted that the right mamma felt as if it contained genuine gland tissue. As far as I remember, he told me nothing of any testicular injury.

It is likewise not easy to apply Decléty's views to the rare examples of mammary enlargement in men following the operation of prostatectomy. Two such cases were recorded by E. Kondoleon[6] in 1920, both in men aged 70 years. In one case the enlargement was unilateral; the right breast began to swell soon after the operation, attaining the size of a walnut, but after a few months the swelling gradually subsided. In the second case the enlargement was bilateral, commencing on the left side about three months after the operation. The progress in the second case is not recorded, as the operation was recent at the time when the paper was published.

I should here like to allude to a very rare and almost acute kind of bilateral gynæcomastia occurring in young men as a pathological endocrine (hormonic) result of a primary adeno-carcinomatous growth of the suprarenal cortex. The first case was shown me in November, 1915, by my then surgical colleague, Dr. J. P. zum Busch, and I have his permission to describe it.[7]

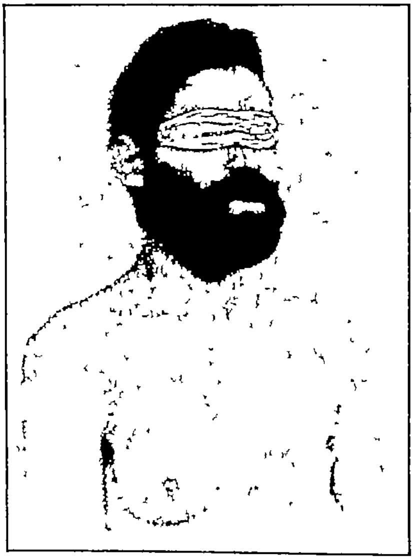
The patient was a male cook, aged 27 years, admitted to hospital on Nov 9th, 1915. For the last two months he had noticed painless enlargement of both mammæ, and he could squeeze a few drops of a slightly milky fluid from the nipple of each breast For the last three weeks there had been also considerable (rather soft) swelling of the lymphatic glands on the left side of the neck. The man died on Dec 2nd, 1915, and post-mortem examination (Dr Hans Schmidt) showed an extensive malignant hypernephroma growing from the cortex of the left adrenal gland, with great numbers of metastatic growths in the lungs. There were some secondary nodules attached to the ribs and vertebral column, seen on clearing out the contents of the thorax; the mesenteric glands were also involved. The enlarged lymphatic glands on the left side of the neck had already, in November, been found (by operation) to contain a very vascular new growth Microscopic sections from one of the enlarged mammæ showed glandular tissue resembling that of an ordinary mamma in the female In this case it seems that a hormone-like substance derived from the actively growing cells of the adrenal cortical adeno-carcinoma had stimulated the male mamma to take on an active secreting function, normal to the female mamma. Prof S G Shattock also kindly examined the sections in this case

Though this observation appears at present to be almost unique, I feel confident that sooner or later it will be confirmed by many similar ones. It may be compared to the remarkable Bittorf-Mathias case, as finally described by Prof E. Mathias,[8] who made the post-mortem examination in July, 1919

The patient was a man, aged 20 years, who had suffered from dyspnœa since March, 1918. In August, 1918, a progressive enlargement of the mammæ was noticed and a few months later the testes commenced to atrophy In February, 1919, the patient became sexually impotent, and in March, 1919, a tumour in the left part of the abdomen was observed The patient developed metastatic tumours in the liver and signs of compression of the inferior vena cava. He died in July, 1919 The necropsy showed that the case was one of malignant cortical hypernephroma. Both mammæ, which had somewhat diminished in size before the man's death, consisted of loose connective tissue containing true mammary glandular tissue. The testes were extremely small; microscopically, there was evidence of spermatogenesis; the interstitial cells were hardly developed.

It would be interesting to know whether enlargement and activity of the male mammæ is ever associated with (benignant) adrenal cortical adenoma, as it evidently may be with (malignant) adeno-carcinoma, and whether any cases of ordinary chronic bilateral gynæcomastia in man are associated with adrenal cortical adenoma.

A point of great interest in Dr. zum Busch's case and in the Bittorf-Mathias case (which absolutely confirm each other) lies in the fact that in both of them a kind of rapidly developed "mammary feminism" or gynæcomastia was associated with a malignant cortical hypernephroma of the suprarenal gland—that is to say, that in both cases the "mammary feminism" developed as a *morphogenic*, endocrine, or hormonic result of functional activity in the carcinomatous cells of adrenal cortical parentage. I need scarcely add that it is well recognised that adeno-carcinomatous growths may sometimes more or less retain the functional, as well as the morphological, characters of the normal glandular cells from which they are derived (compare the well-known presence of a bile-like substance in primary carcinomata arising in cirrhotic livers) But the morphogenic effect of the growth in the above cases (the two young men) was very different to the previously recorded morphogenic effects of primary adenoma or adeno-carcinoma of the suprarenal cortex in children and young women[9]



Unilateral (right) gynæcomastia in a man aged 34 years.

I should here also mention that true bilateral hypertrophy of the breasts in males due to hormonic (endocrine) stimulation has been noted in certain rare cases of teratoma testis and its metastases Prof. H. W. B. Cairns included two such cases in his recent Hunterian lecture on Neoplasms of the Testis,[10] and he referred to other cases (one each) observed by E. Garbarini, J. V. Cooke, Warthin, and A. Malloch. In three of the cases (those of Cooke, Warthin, and Malloch) chorion-carcinoma was present in the testicle. Cairns remarked that the cases in question provided "indirect evidence in support of E. Starling's original contention[11] that the normal fœtus produces a hormone which acts directly upon the breasts"

1 Cf. Lacaille "Trois cas d'acromégalie paraissant unilatérale," Société de Médecine de Paris, meeting of April 10th, 1914. The existence of such cases may be denied but why should not a unilateral response to some general hormonic stimulation occur in very exceptional cases? Can one not conceive the possibility of what one might call a "potential hemi hypertrophy" being present, ready to be converted into actual unilateral hypertrophy or gigantism by hormonic stimulation? Moreover, in thyreotoxism or hyperthyroidism (that is to say, in Graves's disease) the exophthalmos is occasionally unilateral or more marked on one side than the other (F. P. W.)

# Clinical and Laboratory Notes.

## A CASE OF RECURRENT INTUSSUSCEPTION.

By Philip R. Hawe, M.B., Ch.B. Liverp.,
SURGICAL ASSISTANT, DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL.

The following is a record of a case of recurrent intussusception which occurred in a female, aged 40 years:—

The patient complained of several attacks of very severe pain in the abdomen, associated with a palpable lump deep to the abdominal wall. Up to three months ago, when the attacks commenced, she had had no abdominal trouble whatever. The pain commenced just to the left of the umbilicus. At first typically colicky in nature and localised in distribution it became a more general agonising cramp, which caused the patient to sweat, and doubled her up, leaving her quite exhausted. She applied pressure to the part and found a tender lump about the size of an orange which varied in consistency, becoming harder with the onset of each pain. The lump was palpable as a rule for some hours after the attack had subsided.

These accounts were confirmed by her doctor, who was called to see her several times, and also by Mr. K. W. Monsarrat. The attacks lasted from one to eight hours, and occurred about three times a week. They may have had some relation to the taking of food, as occasionally they commenced an hour or so after a meal. The intervals were not quite free, as a dragging pain was present continually in the right iliac fossa. There was no history of melæna, and constipation was only occasional. Borborygmi and flatulence had, since the onset of these attacks, been usual after all types of food. History relating to urinary and other systems appeared normal. Some loss of weight had occurred since the onset of the illness.

After admission to hospital several abdominal examinations were made with varying results. On one occasion a mass was palpated in the region of the transverse colon, which slowly became smaller and smaller on gentle manipulation until it disappeared. At its largest the lump was soft and tender, somewhat elongated, and about the size of a closed fist; it did not pit on pressure, nor was it definitely mobile, but, as described, gradually disappeared. Further examination revealed nothing else abnormal except tenderness in the right iliac fossa. There was no visible peristalsis, and examination of rectum, urine, fæces, and also an X ray examination gave negative results. As a rule, during the intervals no lump was present.

As the lump had been palpated quite definitely on several occasions, even after enemata had been administered, operation was undertaken. On opening the peritoneal cavity the transverse colon presented, and the nature of the lesion was immediately evident. An intussusception of the colocolic type was present and was reduced without the least difficulty. The apex of the intussusception, which had reached the middle of the transverse colon, was formed by the wall of the cæcum with the opening of the appendix as centre. There were no adhesions between the layers of the intussusception, but the apex formed a mass which was circular in shape, very thickened and œdematous, and about the size of a five-shilling piece. The appendix was adherent to the posterior surface of the cæcum and extended towards the hepatic flexure behind the ascending colon, to which it was also bound. It had evidently been secondarily invaginated, base first, with the rest of the cæcum into the colon as the intussusception progressed. Appendicectomy was then performed. In view of the induration of the cæcum round the base of the appendix, it was thought better to excise this part of the cæcal wall. No evidence of new growth or cause for the intussusception could be found, with the exception of an excessively mobile cæcum and ascending colon. Accordingly, after closure the cæcum was fixed to the iliac peritoneum to prevent any possibility of recurrence. From the situation of the apex of the intussusception it was obvious that the appendix had not been primarily involved. Subsequent microscopical examination of the excised portion of the cæcum showed œdema with some fibrosis and mild inflammatory reaction, but no sign of new growth.

It is quite clear from the history and the operation findings that the patient had suffered from a series of recurrent intussusceptions with spontaneous reduction after the attacks had lasted some hours. The absence of melæna and of adhesion between the layers of intussusception is to be explained by the failure of interference with the blood-supply of the affected parts. This type of intussusception probably corresponds to the rare type of recurrent intussusception of older children which, in contrast to the intussusception of infants, rarely, if ever, gives rise to acute complications. Some irregularity of peristalsis seems to be the only explanation of its occurrence. As is well known, some form of neoplasm usually originates intussusception in adults. In this case, however, when the intussusception had once occurred the œdematous apex predisposed to a recurrence. Some of the attacks had been related to the taking of food, the pain having been felt about an hour after meals. Probably the gastrocolic reflex had occurred as usual, followed by active cæcal movements, and after some time the intussusception had reached dimensions sufficient to give rise to severe symptoms.

My thanks are due to Mr. Monsarrat for his permission to publish this case.

## PNEUMOCOCCAL MENINGITIS: CISTERNAL PUNCTURE.

By A. H. Douthwaite, M.D., M.R.C.P. Lond.

The publication in The Lancet of April 10th by Dr. V. M. Synge of a recovery from pneumococcal meningitis prompts me to put on record the following case which was under my care:—

A girl, aged 15, was first attended on July 25th, 1925, on account of headache. She had suffered for several years from chronic nasal catarrh. Pain in the cranial vertex started two days previously and was attributed to sunstroke following a long char-a-banc ride.

On *examination* no abnormality was found of the cranial nerves, tendon, and skin reflexes. Kernig's sign was absent. The skull was tender to percussion. The decubitus was striking, the girl lying on her side with the head well retracted, a position which was retained when she turned from one side to the other. Temperature 100°F., pulse 120, respiration 20. No other signs.

On the following day Kernig's sign was present, as was also blurring of the right optic disc. Lumbar puncture was performed, and 30 c.cm. of turbid fluid removed. This contained 0·7 per cent. albumin, 1000 cells per c.cm., of which 48 per cent. were polymorphonuclear leucocytes. Cultivation gave a rich growth of pneumococci (not typed). On the 27th head retraction was less marked and the temperature had fallen to 99°. The plantar responses were extensor. Nystagmus present. Every two to three days for the subsequent two weeks profuse epistaxis occurred with transitory relief of headache. The evening temperature rose during this time to 103°. Over the same period three further lumbar punctures were performed and 20 c.cm. of Pasteur antipneumococcic serum introduced intrathecally. On August 9th cisterna magna puncture was carried out

under a general anæsthetic (rendered necessary by head retraction) and 35 c.cm. of turbid fluid containing 800 cells per c.cm. removed; 10 c.cm. of serum were introduced. Head retraction and Kernig's sign were absent on the following four days and the patient became mentally more alert. This process was repeated on the 20th owing to a gradual return of all symptoms except epistaxis. The cerebro-spinal fluid then contained 0·4 per cent. albumin and 57 cells per c.cm. Steady improvement followed and the temperature was normal by Sept. 10th.

When seen again in January, 1920, no abnormal signs could be detected and, with the exception of occasional headaches in the right temporal region, no symptoms could be elicited.

Puncture of the cisterna magna is actually a very simple performance, and appears in some cases to produce greater relief than that procured by the lumbar route. Any serum introduced will, of course, reach the affected areas in greater concentration by the former method.

Worthing.

## A CASE OF $CCl_4$ POISONING

### DUE TO THE BURSTING OF A PATENT FIRE EXTINGUISHER.

By L. A. Dingley, M.D. Lond., F.R.C.S. Eng.,
HON. SURGEON, WEST BROMWICH AND DISTRICT HOSPITAL;
VISITING SURGEON, HALLAM HOSPITAL.

The risk of a repetition of the accident described in this article with possibly more serious consequences justifies the reporting of the case, together with a brief summary of the effects produced by inhalation of the chemical in question, especially as a search in the literature has failed to show any cases previously reported.

The patient is a motor-'bus driver. On March 8th he stopped his 'bus, and his attention was called to the fact that a passenger had accidentally knocked down the patent fire extinguisher carried by these vehicles. He climbed down from his seat and, on examination, found it was leaking, and decided, owing to the leakage and bad smell, to do away with the contents. Whilst pulling the handle of the extinguisher out, preparatory to emptying it, the gas and fluid came up into his face. He first noticed burning of his eyes, and rushed into a neighbouring shop where he was advised to put his head into a bucket of water to wash out the fluid. This he did, and then lost consciousness for about 45 minutes.

A policeman on duty near by was called in, and he found the patient propped up in a chair with his head supported by an onlooker. He was quite unconscious, with eyelids closed, which on opening disclosed a fixed and glassy stare, his mouth was closed but easily opened, the pulse was imperceptible, and the mirror test showed that respiration had ceased. With commendable promptitude the policeman commenced artificial respiration by Silvester's method, and carried on for 20 to 25 minutes when the patient commenced to breathe with faint and shallow respirations. He was then given a few ounces of strong tea.

When seen by me he was just regaining consciousness, his eyes were red and injected, he was trying to sit up, and behaving generally like a person coming round from an anæsthetic. His breathing was rather heavy and his pulse 80 and regular. The patient was sent on to the hospital, and on the way the policeman informed me that he again became unconscious but continued to breathe evenly and regularly and his pulse remained slow and full, and he recovered consciousness in a few minutes.

Condition on *Admission*.—The patient had practically recovered consciousness and showed no physical signs of note. Owing to the difficulty and delay in discovering for certain what the extinguisher contained, and in order to avoid any possible delayed action of the drug on the heart, the patient was kept in bed for two weeks, and then allowed up for a few days. His convalescence was uneventful. Before discharge exercise tolerance tests were carried out and provided quite satisfactory.

The motor omnibus company gave me every assistance and were good enough to reply promptly to my letter, informing me that the chemical used in these extinguishers was carbon tetrachloride ($CCl_4$), and that it was 99·95 per cent. pure and contained neither acid nor alkali. Carbon tetrachloride is a heavy, colourless liquid with an aromatic odour and boiling at 76·7° C. It is readily vaporised into a colourless vapour 5·33 times heavier than air. This property, together with its non-inflammability, makes it a most valuable agent in shutting out the air from surfaces blanketed by it, thus rendering it most useful in extinguishing fires.

Carbon tetrachloride first claimed the attention of the medical profession in December, 1865, when J. Y. Simpson, of Edinburgh, suggested its use as a general anæsthetic. Its alleged heart depressant properties, however, soon led to its abandonment. Lewin[1] reports that it is about twice as toxic as chloroform. In the early part of the century it was used as a shampoo, but Colman[2] issues a warning, stating that it is dangerous to life; a fatality from similar use has been reported.[3] Carbon tetrachloride is used commercially in the preparation of golf balls, and a case of intoxication has been reported.[4] It is also in use in millinery establishments where a mixture of this chemical with benzol is used as a cement for fixing material to hat shapes. Several cases of non-fatal poisoning were reported by E. B. Starr,[5] but in these cases the symptoms seem to have been mainly due to benzol.

Medically carbon tetrachloride has been recommended as a treatment for hookworm by Hall,[6] but the treatment has been shown by Meyer and Pessoa[7] not to be devoid of danger. The pharmacology of carbon tetrachloride has been worked out in great detail by Lamson and his co-workers[8] at the Johns Hopkins University, and from this work several important facts are made evident. The case under consideration was caused by respiration of the drug, and for full particulars of the effects when taken by the mouth, by injection into veins or intrathecally, and for the pathological findings, reference should be made to the original article. If large doses are inhaled, respiration ceases and the blood pressure falls rapidly, which, in early cases, may be combated by continuous and persistent artificial respiration. It further transpires that alcohol is distinctly dangerous, and should not be given, as it greatly increases the rapidity of absorption and the toxicity of any of the chemical which may have been swallowed.

### *Treatment.*

In cases of escape of this gas, it is important to see that no person, especially if helpless or injured, is allowed to remain on the floor level, owing to the heaviness of the gas. The respiration should be carefully watched, and should be artificially carried out if necessary, and be persevered with for a very considerable time. As a stimulant alcohol should be avoided, resource being made to some watery solution such as strong tea or coffee. Such cardiac stimulants should be used as are used in chloroform poisoning.

Street Accidents in Sheffield.—At the annual meeting of the Sheffield Royal Hospital it was stated that the hospital deals with 400 street accidents a month, many of them due to the carelessness of pedestrians.

The Government of Bihar and Orissa has constituted a permanent cadre of public health officers consisting of 27 assistant surgeons. The new cadre is under the Director of Public Health and is distinct from the medical department.

## ROYAL INSTITUTE OF PUBLIC HEALTH: ANNUAL CONGRESS, BRISTOL, MAY 19TH–24TH.

THE Congress, which ended at Bristol on Monday, was attended by more than 300 delegates, a number of whom came from distant parts of the Empire and from foreign countries.

### *Opening Addresses.*

The inaugural meeting was held in the Great Hall of the University. The Lord Mayor of Bristol welcomed the visitors.

The DUKE OF BEAUFORT (High Steward of Bristol, President of the Congress), after referring to the wonderful progress made in the last 50 years, said the bewildering programme prepared for the delegates indicated that hygienists did not intend to rest on their laurels, and expressed his conviction that such congresses must play an important part in shaping public opinion on health matters. Alderman FRANK SHEPPARD (Chairman of the Housing Committee) claimed the great interest now taken in housing conditions as of good augury. The Under Secretary of the Egyptian Health Department voiced the strong desire of the Government of King Fuad to promote the cause of public health both within and without Egypt. The geographical position of Egypt gave her an important share in the defence of humanity from the scourge of disease. The Dean of Bristol expressed the welcome of the churches and his belief that the visitors would find that Bristol was giving a noble lead in caring for those engaged in her industrial activities. Miss TOWNSEND (Chairman, Infant Welfare Association) referred to the enthusiasm of the Bristol women in this work. Dr. C. BENTLEY (Director of Public Health, Bengal) described how cholera and other diseases were being brought under control. Brief speeches were made by representatives from France, Belgium, California, and Australia, and subsequently a reception was given to the delegates by the Council of the University, the guests being received by the Vice-Chancellor and Mrs. LOVEDAY.

The work of the Congress was divided among five sections: (1) State Medicine and Municipal Hygiene; (2) Naval, Military, Air, and Tropical Diseases; (3) Industrial Hygiene; (4) Pathology, Bacteriology, and Biochemistry; and (5) Women and the Public Health.

### *Bovine Tuberculosis.*

The problem of improving the milk-supply was opened by Dr. W. G. SAVAGE (M.O.H., Somerset) with a carefully drawn-up criticism of the working of the Tuberculosis Order which should be of great value to the Board of Agriculture. The Order and Regulations read well from the preventive point of view, but do not so work out in practice, says Dr. Savage. So far, in Somersetshire, the manifestly tuberculous cows are being destroyed too late, there is a marked absence of effort to find udder disease at an early stage, there is no systematic examination of the rest of the herd following the discovery of an infectious animal, and little attempt to bring home to the farmer the importance of the matter.

Dr. C. E. TANGYE (M.O.H., Wilts) stressed the importance of regular inspection and said his county council was moving in the direction of a whole-time veterinary inspector. Dr. STENHOUSE WILLIAMS was more optimistic as to the progress being made and suggested that too much must not be expected from the first seven months' operation of the Order. Lieut.-Colonel C. MADDOCK, M.D. (Secretary of the Grade A (tuberculin tested) Milk Producers' Association), described the progress that was being made in the production of this grade of milk and asserted that if herds had been freed of tubercle for a twelvemonth they could, with reasonable precautions, be kept free for many years.

Dr. R. KING BROWN (M.O.H., Bermondsey) described the propagandist methods adopted to promote the sale of this milk in Bermondsey—street corner lectures, distribution of pictorial pamphlets, &c., and mentioned that the borough council had decided to accept only this grade of milk for their hospitals and infant welfare centres.

Surg.-Admiral Sir PERCY BASSETT-SMITH gave an interesting presidential address to the "Services" Section on the relation of diseases of animals to those of man and made special reference to new developments with regard to undulant fever. In France and Spain there was a tendency for this disease to spread inland, and in France the infection was being spread by sheep. In Rhodesia, America, and Italy infection had been traced to cattle and an organism similar to *M. melitensis* had been found in bovines.

### *Rheumatism.*

Dr. A. P. THOMSON (Birmingham) read a paper on the rheumatic child, and Dr. CAREY COOMBS (Bristol) and Dr. M. B. RAY (London) and Dr. R. E. THOMAS (Bath) were amongst the chief contributors to a general discussion on this subject at the Pathological Section. Dr. C. PRESTON BALL (Dublin) dealt with the relation of oral sepsis to rheumatic diseases. Dr. COOMBS stated rheumatism was less frequent than 20 years ago and that there was strong evidence in favour of a causal streptococcus, which might be a normal inhabitant of the intestine converted from a saprophytic to a pathogenic type. Dr. RAY attached importance to diathesis and did not think the results of tonsil enucleation were conclusive. Dr. THOMAS mentioned that the nodules described by Dr. COATES as an early sign were rarely found before the age of 3. He had, however, found them once at the age of 14 months. Their incidence varied in the various schools of Bath and also as between one town and another. Any child with nodules should be kept under careful observation. An excess of carbohydrate in the diet might have a causal effect. From a preventive point of view, perhaps the most important point emerging from the papers and discussion was the need for effective education of both parents and school teachers in the very indefinite early signs of rheumatism, usually with no joint symptoms, so that the children may be treated before irreparable damage is done to the heart.

### *Racial Progress.*

On the second day the women's section discussed the improvement of the race.. The problem was attacked from different angles. Dr. INNES PEARCE urged the greater importance of environment and that parents can only provide the right soil for the seed by their own culture and development. Race culture therefore meant parent culture. One must get at the newly-married couples. It was too late to try to break the vicious circle after four or five children had been born. Centres might be used to some extent as family clubs. The present haphazard outlook towards conception and parenthood must be abolished.

Dr. LETITIA FAIRFIELD (P.H. Dept., L.C.C.) reviewed optimistically the present position, after the ten years' campaign against venereal diseases. More and more gonorrhœa in women was receiving adequate treatment. Formerly all sterility was attributed to the woman, but it was now known that at least 25 per cent. of it was due to the man. Syphilis was still the greatest known cause of premature still-births. A positive Wassermann in a newly-born child was often only a "carry-over" from the maternal blood, and did not imply congenital syphilis. Only a very small percentage of the London school-children showed evidence of congenital syphilis. Mental degeneration was very rare and when it did occur was followed by the well-known affections of the special senses. Apart from these rare cases there was no evidence that syphilis in the parents caused mental deficiency in the child. The cures and the continuity of attendance of the cases at the V.D. centres went on increasing and there was a decline in the deaths attributed to congenital syphilis.

Dr **STELLA CHURCHILL**, L.C C, spoke on the *feasibility of health certificates before marriage*, and mentioned that such certificates were being encouraged by the German Government

Mrs. C S **HODSON** (*Secretary, Eugenics Education Society*) mentioned that the work of the V D centres was dysgenic in that it helped the propagation of the immoral and incontinent *section of the* community She did not, when questioned, put before the meeting any practical proposals for scientific mating

Dr D S **DAVIES** (M O H, Bristol), who in an interesting paper read the previous day on Random Recollections of Forty Years' Service, had stressed the enormous importance of heredity and prophesied that race culture would be the task of the coming hygienist, said humanity could not help caring for its weaklings but that we ought to try to prevent the propagation of the unfit

The practical suggestions arising from the discussion were early teaching of the facts of life to boys and girls, and the education of both sexes for parenthood

### *Cancer*

Dr J G **ADAMI** (Vice-Chancellor, Univ of Liverp ), in opening a discussion on cancer at a joint meeting of the State Medicine and Pathology Sections, reviewed the present position and expressed the opinion that, without believing that in colloidal lead Prof Blair Bell had discovered the ideal substance for arresting cancer, a huge advance had been made. He believed *that from now onwards* medical research would chiefly concern itself over the provision of better and surer methods of arresting cancerous growths There were *many causes* of cancer, and the more hopeful line of attack appeared to be how to end cancer rather than finding out how it began He did *not believe that the campaign of education* would lead to cancer-phobia ' The same warning had been *thrown out when the campaign against* tuberculosis started and had proved ill *founded* He advised every medical man, to whom a patient came with a lump in the breast, &c *not to send them away with* comforting words, but to see them *again and keep* in touch with them, so that surgery, if needed, might be employed successfully

Commander O **LOCKER LAMPSON**, M P, speaking as a layman, made a stirring plea for a braver outlook. After three years in Russia, where death was disregarded, it was astonishing to return to this country and find all this fear of death After all it was better to die of cancer at 52 than from tuberculosis at 22 By getting rid of this fear we should get early operations with a large majority of cures Recent discoveries indicated remarkable progress. We must therefore with hopeful confidence, provide adequate support for research work.

Other interesting discussions were those on silicosis factory hygiene vocational selection, the care of the crippled child advance lines in maternity and child welfare, and the health of women industrial workers. The sections were well attended, interest being kept up to the finish, and the Congress fulfilled its purpose of directing public attention to every branch of health work

---

A **YEAR BOOK OF LEARNED SOCIETIES**.—For the forty-second year in succession the *Year-Book of Scientific and Learned Societies* has been produced by Charles Griffin and Co, Ltd. of 12, Drury lane London W C 2 This book is a guide to the societies and Government institutions of Great Britain and Ireland and briefly records the work done in literature science and art during the session 1924 25. There are so many separate organisations that a reference work of this kind is essential and long experience has enabled this firm of publishers to provide just what is wanted. It is equally attractive to those who have a taste for the desultory acquirement of general knowledge and to those whose work involves hurried *reference* and thus it *fully justifies the claim to have* helped men to enjoy life or the better to endure it " The price is 15s, and the book contains over 100 clearly printed pages.

## ROYAL SOCIETY OF MEDICINE.

### SECTION OF ELECTRO THERAPEUTICS

A MEETING of this Section was held on May 21st, Dr **ALASTAIR MACGREGOR**, the President, occupying the chair

Dr H. **EATON STEWART** (*New Haven, U.S A.*) read a paper on

### *Diathermy in Pneumonia*

The earliest attempts, he said, to use diathermy in *pneumonia were made by two Americans*, F De Kraft and Byron S Price, of New York, about 1000 When Dr Stewart began to use it in 1921 he was unaware of this previous work. In that *year a severe epidemic of* the disease occurred in a New York marine hospital, to which he was consultant in physiotherapy, and on the assurance being given that it was reasonably safe, diathermy was allowed to be tried experimentally on a case in which there seemed to be no other chance of recovery The eleventh day of the illness had been reached, and the man's family had been informed that the case was hopeless He was given a through and through antero-posterior diathermy, with bare composition metal plates, 2000 milliampères, for 20 minutes; the clinical improvement was immediate and marked, and with applications twice daily he made an uninterrupted recovery In order to make the study of scientific value each case was observed, written up, and checked by the medical staff, X ray and laboratory reports being made by them, and no change being made from the usual medicinal, nursing, and dietetic care In the next 20 cases treated in this way there was only one fatality—in a patient who was moribund from the start During the rest of that season every third case was used as a control Forty-one cases were submitted to diathermy, and the death rate was 17 per cent , while 21 control cases, treated similarly *except for the diathermy*, gave a mortality of 48 per cent Publication of these results led to an extension of the treatment in both private and hospital practice in the States Miller, *of* Prague, seemed the only one who had treated a series in this way in Europe.

*Technique* —He used bare, flexible, metal electrodes, *covered with a heavy shaving-soap lather*, placed directly on the skin *antero-posteriorly* For single lobe treatment in the adult the area of the electrodes used was 5 by 7 *in* , *for two adjacent lobes*, 0 by 8 in. There had been a considerable use of German silver chain material, as such electrodes easily conformed to the chest contour In order to keep the plates warm it was well to have the *cords already inserted* in the d'Arsonval terminals and the electrodes prepared singly A folded bath towel could be *tucked underneath* to ensure good contact The upper plate was similarly prepared, placed in position, and was usually retained by the spread finger tips of the operator, who was then able to manipulate the *apparatus* with his free hand No weight must be placed on the anterior electrode Four minutes was the time occupied in raising the current to 1200 to 2000 *milliampères*, according to the requirement of the case

With regard to dosage, experience had shown the advantage *of giving longer treatments of a lower* milliampèrage—i e , instead of 20 minute applications at 2000 milliampères, 1200 to 1400 m.a for 30 to 40 minutes was preferred In very severe cases Dr Stewart had given 2100 m a for an hour at hourly intervals In private practice severe cases were treated every four hours, omitting early morning *application* It seemed to be advantageous to have the cardiac area included in the pathway of the current, as when treating a lower left lobe involvement; this *had been confirmed* by a number of workers

### *Clinical Results*

The clinical results *given* were *based* upon over 300 cases There had been a fall of the temperature by lysis in 07 per cent of the cases, in many this fall set in on the second or third *day* *In 1 per cent*, *in* which there was a deficient power of reaction in the patient, the application was followed by a sharp rise in temperature, then by a fall by lysis and a slowed pulse- and respiration-rate. This doubtless conserved the energy of the body. Another almost invariable result of the treatment had been a lessening of cyanosis when that was present, and this improvement was especially marked when the left lower lobe was involved. Probably it was because the relief from pain permitted of greater respiratory excursion, and also because there was a better intrapulmonic circulation around the area of consolidation. Under the treatment the respiratory rate was lessened by about five per minute, and in most of the cases the respiratory grunt disappeared permanently after the first treatment. The freedom from pain which the treatment conferred allowed the patient to marshal his powers of resistance and this seemed often to have been a determining factor in recovery. Sleep seemed to follow naturally quite early. Extension of the disease occurred under this treatment in about the same proportion of cases as when the treatment was not given. But since electrodes had been introduced sufficiently large to influence adjacent tissue, extension of the disease had occurred in fewer cases. Practically every application was followed by increased perspiration; when this was not too profuse it probably helped the elimination of toxins.

Empyema developed in about two-thirds the number of cases to be expected under other treatment.

Some writers contended that the heat developed in the patient's body by the diathermy was bactericidal, but Dr. Stewart thought that if this were so the disease would terminate as soon as the treatment was started; this did not occur. But the heat which was generated hastened resolution. When, in a few cases, resolution occurred quickly—too quickly—with signs of toxic absorption, the diathermy was at once stopped. It was necessary to speak very guardedly about mortality, for the death-rate from pneumonia varied widely in different epidemics. Dr. Stewart was able to say, however, that in four series of cases, checked by controls, the death-rate had been roughly halved by diathermy. The ascertained grand average death-rate to date was 12·9 per cent., including various seasonal epidemics, and embracing streptococcal pneumonia. No cases were refused the treatment, even if they were moribund. In 42 of the recovered cases the attendant physicians had abandoned hope. There were only two deaths in the whole series in which diathermy was applied before the third day. Favourable comments on the treatment had been made by 90 clinicians who had closely followed the progress of the cases. From every standpoint the treatment appeared to be safe and conservative, but Dr. Stewart studiously avoided the word "cure" in reference to the procedure.

### *Discussion.*

Dr. E. P. **CUMBERBATCH** said that when he went to the United States last autumn he made a point of asking each clinician he met there—both electrical and medical—what his experience of this treatment was. All thought very highly indeed of it, and he did not encounter anyone who doubted its efficacy. Dr. Stewart's book on the subject was a masterpiece of thoroughness.

Dr. W. J. **TURRELL** (Oxford) said that from considerations of logic many had felt for some time that diathermy ought to benefit pneumonia, but hospital physicians to whom the method was recommended showed great reluctance to adopt it. One physician to whom he spoke on the subject said he could understand that diathermy might help in some cases of pneumonia, but he did not see how it could help grey hepatisation of the lung. He told that gentleman that the condition was a post-mortem condition. In diathermy the slower one reached the maximum current to be employed the better it was for the patient, but he thought no one would have anticipated from theoretical considerations that 98 per cent. of the cases would terminate by lysis instead of by crisis. But what was lacking in this country was a portable apparatus, so that the electro-therapeutist could go to the homes of patients and give them the treatment there. He asked whether a portable apparatus was in use in America.

Dr. C. B. **HEALD** said he also could speak of the reluctance of hospital and other practitioners to adopt this treatment. He had treated by the method a case of acute lobar pneumonia, two of delayed resolution, and four of broncho-pneumonia. When his own baby, aged 3, was almost breathless with broncho-pneumonia, the respiration-rate being 52, he fearlessly used the treatment, feeling that it would bring quiet. The effect was remarkable, for long before any appreciable concentration of current was reached there was a definite change in the type of breathing. That had been very noticeable in all his cases which had been treated in this way. One of these was a doctor, aged 36, who had double pneumonia three weeks before diathermy was commenced, and he was sleeping badly and was breathless on exertion. There were few or no signs of resolution. Two heart-shaped electrodes, covered with lint, were used, and as soon as the current was turned on the patient said he felt comfortable, and after the first application he enjoyed a good night. 2000 m.a. caused restlessness, and this patient himself was able to say what strength of current suited him best.

Dr. G. B. **BATTEN** asked about the comparative values of the open and the closed spark-gap, the latter being the usual form in this country, whereas the United States practitioners seemed to prefer the open form. He also referred to the greatly increased permeability of tissue to current according to the strength used; Phillips, of Belgium, showed that tissue was eight times as permeable to a current of 200,000 as it was to one of half that strength. He did not agree with Dr. Stewart that if diathermy acted as a bactericidal agent it would cure at once; his own view was that it first greatly lowered the microbial activity, then became lethal to the organisms.

Dr. **STEWART**, in reply, said the profession in the States was fortunate in having several makes of portable instrument for the purpose, giving currents of 75, 110, and 220 volts. They were quite reliable. He averred that the profession in America also took up a conservative attitude in regard to anything new, and he had every respect for the physician who could say he had watched a certain kind of treatment and was not impressed by it, but not for one who objected to it when he had never seen it. He also had noticed there was a change in the type of respiration following the application of the current. In America triple gaps were largely used; some open, some closed, and, except for the noise, he did not think there was much to choose between them. He contended that the lowering of the temperature by lysis at an early stage must effect a great saving of the body resources, for heat was placed there without the body's aid. Among the 143 cases to which diathermy was applied before the third day of the illness, only one died. Good work was now being done at the Crile Clinic to show how electricity could be used to greatly reduce the surgical shock which followed major operations. A very important point about this treatment for pneumonia was its safety.

---

**PURE MILK FOR LIVERPOOL HOSPITALS.**—The Liverpool Port Sanitary and Hospitals Committee is endeavouring to improve the quality of the milk-supply to the city hospitals. It reports that although the milk is the best that can be obtained in the district, it is not equal to that produced by the farms visited by the committee in Berkshire. The experience gained in visiting those farms showed that, without any costly buildings, cows can be maintained in thoroughly hygienic premises and their milk produced under extraordinarily clean conditions at very moderate expense. The whole of the milk consumed in the Liverpool hospitals comes from the great dairying district of Cheshire where, the committee thinks, there ought to be little difficulty in keeping tubercle-free cattle. If the Liverpool hospitals were supplied with Grade A Tuberculin-tested milk at present prices the extra cost would be about £1500 per annum.

## HEALTH LEGISLATION.

*Public Health Law.* By JAMES A. TOBEY, M.S., LL.B., Lecturer on Public Health Law, Massachusetts Institute of Technology, Yale School of Medicine, and Columbia University. Baltimore: Williams and Wilkins Company; London: Baillière, Tindall and Cox. 1926. Pp. 304. 20*s.*

THERE are very few actions taken by a public health official which may not be questioned in court of law. It behoves him, therefore, to walk circumspectly and to bear in mind the risks he is taking, yet not to lack the courage to take risks in case of need. For example, any removal of the environmental disabilities of the people has to be carried out strictly within the letter of the law, which also must be observed punctiliously when any restriction of the freedom of individuals in the health interests of the community has to be enforced. This means that the public health expert has to convince the majority of the people concerned before he can obtain power to apply compulsion to the individual, which is good for both the expert and the public. For these reasons we have a growing volume of literature on public health law, or sanitary law as it is unfortunately called in this country, ranging from the "cram" book for students to the formidable annotated reproduction of Acts of Parliament which gives lengthy and sometimes contradictory legal judgments on debatable points.

This book falls into a category intermediate between the two classes of publication mentioned, and though it deals primarily with American public health law, is of sufficient general interest to be worth study outside the United States. Mr. Tobey commences with a general discussion of public health in its legal aspects, going on to trace the development of American public health law from its sources in the common law inherited from England to the form into which it has been moulded in the various States within the framework of the American constitution. The sanitarian of this country must be impressed on reading the book with the similarity between American law and our own, in spite of the opportunities for divergence afforded by the constitution of the two countries. An interesting feature is the meagre space devoted to the legal problems arising out of the law of nuisances, drains, &c., which occupy so much space in most English manuals of sanitary law, and, on the other hand, the introduction of the subjects of mental and social hygiene. Modern health officers will agree, we think, with the author's view, which has also been frequently stressed by Dr. Charles V. Chapin, who writes a foreword to this book, that the "nuisance" is a greater nuisance to the health departments than it is to the public.

This volume will prove valuable and interesting to public health officials of all nationalities.

*Health Legislation.* For Students of the Health Services. By Lieut.-Col. F. HARVEY, R.A.M.C. (Ret.), M.R.C.S., L.R.C.P., D.P.H. London: H. K. Lewis and Co. 1926. Pp. 207–x. 8*s.* 6*d.*

Colonel Harvey, who has much experience both of the practice and the teaching of sanitary law, has written a tightly packed summary for the use of health visitors, school nurses, local government and sanitary inspectors, and other social workers. He brings together, in a handy form, a mass of Acts and regulations, and, for the benefit of prospective candidates, adds a few typical questions from recent examination papers. Although the author did not manage to insert a mention of the Dangerous Drugs Act of last August, and although his references to workmen's compensation will require correction in view of the consolidating Act passed before Christmas, the book contains the latest information and explains the Housing Act and the Public Health Act of 1925, and numerous important regulations issued by the Ministry of Health last year. A few minor criticisms may be offered. The table of abbreviations in a much abbreviated book might more conveniently be placed at the beginning than on p. 22. In discussing the departmental transfers of powers under the Ministry of Health Act, reference does not seem to be given to the partial transfer of lunacy and mental deficiency powers from the Home Office in May, 1920. The otherwise excellent historical introduction has an entry "1920. The 'Sir' Loin knighted by Henry VIII.," of which the significance is not made apparent; an entry might perhaps have been better made against the year 1662 to Petty's Observations upon the London Bills of Mortality, which gave us our first vital statistics. Doubtless, because of the vigorous compression which governs the book, an occasional sentence reads awkwardly. Thus it is stated on p. 19 that "Statutory Acts are Acts of Parliament which have received sanction of the Crown"—as though some Acts were perhaps non-statutory or did not receive the Royal Assent—and on p. 38 that "The Vaccination Acts, 1867 to 1898 and 1907, include a number of Orders and Regulations made under those Acts," when it is presumably meant that the Acts authorise the making of orders and regulations. These are trivial points, perhaps, and there is a remarkable fund of accurate information in this little book which both students and workers will find helpful.

## MEDICINE.

*A Text-book of the Practice of Medicine.* Second edition. By Various Authors. Edited by FREDERICK W. PRICE, M.D., F.R.S. Edin., Consulting Physician to the Royal Northern Hospital; Physician to the National Hospital for Diseases of the Heart. London: Oxford University Press. Pp. 1864. 35*s.*

IN this edition this popular text-book has been thoroughly revised and brought up to date. Slight alterations in classification have been made, and rickets is no longer classified under deficiency diseases, but under diseases of metabolism. Many articles have been added and others rewritten. Among the additions are articles dealing with the Schick test in diphtheria and the Dick test in scarlet fever and quinidine therapy. The last named gives a clear account of the indications, methods, and dangers of this form of treatment. Of the sections rewritten, that on diabetes mellitus and the treatment of diabetic coma is of outstanding excellence. As in the first edition, among the best sections in the book are those dealing with diseases of the central nervous system. Sections dealing with the mental sequelæ of encephalitis lethargica and paraphrenia have been added, and the accounts of epilepsy, aphasia, and defects of speech, hysteria, neurasthenia, and dystrophia myotonica have been rewritten. The part played by metabolic disorder in the ætiology of epilepsy receives special notice.

The book is well indexed and clearly written. With every advance it becomes more difficult to produce a book dealing with every section in medicine adequately and in sufficient detail to make it of use. The need for a second edition so soon after the publication of this text-book shows that the requirements of both practitioner and student have been met in its pages, and its further success would appear to be assured.

*Text-book of Differential Diagnosis of Internal Medicine.* By M. MATTHES, M.D., Professor of Medicine, University of Königsberg. Authorised translation of the fourth German edition by I. W. HELD, M.D., and M. H. GROSS, M.D., New York. London: J. and A. Churchill. 1925. Pp. 908. £2 2*s.*

THIS well-illustrated and beautifully-printed volume should appeal to those readers who, being unfamiliar with the German language, are still desirous of studying the German point of view on medical problems. Prof. Matthes's book is well written, full of interesting facts, and provided with references to quite recent German literature. The translators have done their work well and have added to certain sections, particularly those dealing with circulatory diseases, in such a manner as to increase the general utility of the volume. The book should be a welcome addition to many medical libraries.

---

### APPLIED ENTOMOLOGY.

*Insects and Diseases of Man.* By CARROLL FOX, M.D., Lecturer on Medical Entomology, Hygienic Laboratory, Washington, D.C. London: H. K. Lewis and Co. 1926. With 92 figures. Pp. 349. 18*s*.

THE first part of this book gives an account, with diagrammatic drawings and diagnostic keys, of the insects and arachnids which are concerned with the spread of human disease; a few mammals such as rats are also included. Its purpose is to enable anyone to identify the practically important species and give them their proper names; accurate systematics are fundamental to modern parasitology, and this section should be useful. The second part deals with the diseases of man transmitted by insects and is less satisfactory; the ground too is already well covered. We notice that barium carbonate and squill are not mentioned under rat poisons.

---

### CHININUM: SCRIPTIONES COLLECTÆ.

Bureau for Increasing the Use of Quinine. Amsterdam. Pp. 262.

THE preface states that the interest with which their first publication (1923) was received has induced the Bureau to publish this second similar collection of papers. It is inevitable that a volume devoted frankly to increasing the use of quinine should give first place, and most space, to malaria; for its treatment rests on quinine, and there is still a steady demand for quinine in its prophylaxis, individual and mass. The place of honour, and a memorial notice, is given to the late grand old man of malaria, Battista Grassi, of whom an excellent and characteristic portrait appears, and a facsimile MS. reproduction of his contribution on the results obtained in the antimalarial fight in consequence of the discovery of the malaria-carrying anopheles. Quinine, of course, has played a part in this fight. As to his own eight years' antimalarial campaign at Fiumicino, he was sure that every year it produced seven times more than it cost; and on the moral side there was no comparison to be made. Next, facing his own portrait, is Laveran's statement: "Malaria is one of the rare diseases against which we can oppose a truly specific remedy—cinchona." Sir Ronald Ross does not here plead for quinine. Opposite his portrait is his brief and cogent summary of the reality of malaria and its meaning in terms of humanity—it is "the principal and gigantic ally of barbarism"; nothing has proved "so inimical to civilisation as this disease." The work of the Malaria Commission of the League of Nations in various countries is recorded and illustrated in a series of papers, as is the like work against malaria in America and the Dutch East Indies. Other papers deal with various problems of malaria, its quinine therapy and its prevention. The risk of getting one's brains kicked out, by barking too close at the heels of error, is well known, so one must admire all the more Clayton Lane's critical consideration of the treatment of the malarias. Intrinsically it deserves the widest note. The adoption of these methods would save much discomfort to patients, and much quinine, and prevent some malaria. Adam, from Dakar, records a case of congenital malaria. The parasites were found in peripheral blood of the mother during labour, and in the umbilical cord blood, and peripheral blood of infant after birth. Certainly this volume contains much of interest and value for the student of malaria, although the evidence, experimental and epidemiological, for the failure of quinine to prevent malarial infection receives in it no other representation than the passing, self-guarding statements of some of the authors that such failure may, and does, occur at times, and that the drug also sometimes fails to cure. Finally, a further series of papers record apparent beneficial results of quinine therapy in a variety of ailments. Prof. Wenckebach contributes an interesting paper on quinine in diseases of the heart and circulation. He relates that once upon a time he had refused to prescribe quinine on the "scientific" grounds that it "really and finally" paralysed the heart. How thoroughly wrong he was was shown when there came to him a patient, "by chance, or possibly not by chance, a Dutchman," who claimed to have a means of getting rid of his own perpetual cardiac arrhythmia, and proved his claim by coming next day with a regular pulse, confessing that he brought this about by taking a gramme of quinine! With the professor one sees how fit it was that such a bearer of the quinine evangel should have been a Dutchman.

As another agent for increasing the use of quinine this volume could hardly be bettered.

---

### HANDBUCH DER TROPENKRANKHEITEN.

Third edition. Edited by Dr. CARL MENSE, with the assistance of many authorities. Leipzig: Johann Ambrosius Barth. 1926. Vol. IV. Pp. 762. R.M.66.

THIS is a bulky volume which in its size and mass of contents rivals its three immediate predecessors. Written in the same exhaustive manner, illustrated with wealth of detail and ample references to the literature, the new edition of Mense cannot be regarded otherwise than as a book of reference. A section on cosmopolitan diseases of the tropics is contributed by Dr. P. Manteufel. Under this heading one might embrace almost the whole of medicine. He has selected for special mention typhoid, typhoid-like diseases, small-pox and its subvarieties, tuberculosis, venereal diseases, eye diseases, measles and scarlet fever, diphtheria, pneumonia, whooping-cough, influenza, mumps, and skin diseases. The list includes many other morbid conditions as well, and it cannot be said that in his efforts to deal exhaustively with this formidable subject the author has been entirely successful.

The information at the author's disposal has not been in all instances of equal value, and no particular advantage appears to be gained by splitting up typhoid-like diseases and the subvarieties of small-pox ad infinitum. Dr. R. Ruge has written a full account of bacillary dysentery; here again an uncritical attitude is observed in dealing with the innumerable variants of the dysentery organisms which have been described. The historical section, which is of little practical use to the modern student, appears to be unnecessarily laboured. Its writer is responsible also for the section on amœbic dysentery, to which the same criticisms might be applied; the text figures and plates illustrating the pathological appearances of the bowel are, however, excellent. Dr. Juliano Moreira, head of the State asylum of Rio de Janeiro, has written an original article on the psychoses and mental disorders of the tropics, under which are included as ætiological factors syphilis, malaria, sleeping sickness, Chaga's disease, yellow fever, leprosy, plague, encephalitis lethargica, beri-beri, and pellagra. Opium, alcohol, and hashish receive attention as the most potent of cerebral intoxicants in native races. Undoubtedly the best and most exhaustive account of verruga peruviana and Oroya fever that we have is the chapter by Dr. H. da Rocha-Lima; it is illustrated by photographs, temperature charts, and an excellent coloured plate of Barton's bodies in the latter disease. Dr. Georg Sticker writes upon the short fevers of the tropics; these suggest dengue and phlebotomus fever and Weil's disease, but the author ambitiously includes in his net such dubious entities as acclimatisation fever, low fever, and many local "fevers," which for the sake of clarity had better have been omitted. It seems illogical that hepatic amœbiasis and amœbic infection of other organs should form the subject of a separate chapter and not regarded in direct connexion with amœbic dysentery, from the account of which it is separated by a *bloc* of over 800 pages. This lack of coördination has led to needless reiterations and much waste of space. Dr. U. N. Brahmachari contributes a chapter on kala-azar; half the space devoted to this important disease is occupied by an exhaustive bibliography, while the section on treatment is mainly concerned with the results of recently elaborated antimony compounds. This section is particularly fully illustrated, especially by means of maps.

This stupendous work suffers from the great disparity in the value of the articles. Moreover, its very completeness tends to make it unwieldy. But the worker in tropical diseases, especially one who is remote from libraries, will find in this volume a complete exposition of the subject. The names of many English authorities in the bibliography are strangely misspelt.

---

### INFANT WELFARE.

By H. H. CHODAK GREGORY, M.D., M.R.C.P., Assistant Physician, Royal Free Hospital; Physician, East London Hospital for Children, Shadwell. *London: H. K. Lewis. 1926. Pp. 141. 4s. 6d.*

THIS little book is primarily intended for practitioners who are engaged on work in infant clinics. The first chapter is directly concerned with the management and scope of the clinic, and the special problems which arise there are discussed. The rest of the book forms a guide to the feeding and management of infants which is equally applicable to the clinic and the home. The advice which is given on nursery hygiene in general is extremely practical and is clearly expressed. The author rather curiously champions the "dummy"—when used for a few minutes only—as a stimulus to sleep. It must certainly be admitted that no harm will arise from its use in this way alone, yet it may be that the French Government, in forbidding recently the sale of the "sucette," have adopted the more prudent course. The instructions on breast and artificial feeding are sound, and have the great merit of being simple. Recognition is given both to the advantage and the practicability of using fresh cow's milk when breast feeding is not possible. It will, perhaps, be helpful to some of the less advanced readers if in a future edition some tables of specimen feeds are included. The book deals in the main with the normal, but the last chapters contain an excellent summary of the significance of some common symptoms.

This is altogether an admirable book, which should be of great assistance to a much larger class than the medical officers for whom it is specially intended. It may be strongly recommended to nurses who are preparing for the examination for the Sick Children's Register, and it should make profitable reading for an intelligent mother.

---

### U.S. MEDICAL DEPARTMENT AND THE WAR.

*The Medical Department of the United States Army in the World War.* Vol. XV. Statistics, Part II.: Medical and Casualty Statistics. *Washington:* Government Printing Office. 1925. Pp. 1308. $3.

THIS is a handsomely printed book of elaborate statistics, set out on large and expensive pages, and sold for 12s. It tells in great detail how the U.S. Army grew month by month, and how it was demobilised, what were the admissions for disease and injury, the discharges for disability, and the deaths in the various classes of soldiers, white, coloured, Filipino, &c., both absolutely and per thousand. Then there are statistics of the health of the individual training camps in the United States, and tables, never before attempted, showing for each day in 1918 up to the armistice how many of each infantry, artillery, machine-gun, and engineer unit were gassed, wounded, or killed in action day by day. A diagram on p. 1020 shows the case mortality of those wounded by each form of enemy action, and the highest case mortality is that from sword wounds. Lest this unduly encourages some devotee of the *arme blanche*, we hasten to add that only 12 of such wounds are reported, of whom 8 died, while of 235 bayonet wounds only 4 died. Of gunshot wounds there were 7474 deaths among 74,883 wounded. There is required some universal notation to show in such diagrams which figures have weight behind them, which have not. In all there were 36,694 (3·6 per cent. of the army) killed in action, 224,089 (21·8 per cent.) wounded, of whom 13,691 (1·3 per cent. of the army) died. Nearly half the infantry became casualties in action. It is interesting to note that admissions for drug addiction increased relatively to those for alcoholism among white soldiers in the United States up to the armistice, and then at once fell off. It is not clear how many men of the Expeditionary Force in Europe died, of what diseases, or what proportion the deaths from disease bore to the deaths from wounds, but in other respects the statistical information offered on the diseases and casualties of the war is of great interest.

### CLINICAL NOTES AND DEDUCTIONS.

Being Fads and Fancies of a General Practitioner. By MARY C. DE GARIS, M.D., B.S. Melb. *London: Baillière, Tindall and Cox. 1926. Pp. 176. 7s. 6d.*

Miss de Garis has evidently given much thought, born of experience, to her subjects. She devotes the first 40 pages to the subject of labour. Labour ought to be practically painless, she holds, and the frequent occurrence of pain is due to primary inertia; this again is thought to be due to certain constitutional factors—e.g., endocrine deficiency and especially dental sepsis and dietetic errors. No very satisfactory facts are adduced to support these hypotheses, but the desirability of more exact obstetrical research is thereby emphasised and advocated. Dental sepsis figures prominently and is given a section by itself, and cases are quoted to show the effects of it in arthritis, psychoses, and renal and cardiac troubles. Shorter articles follow on whooping-cough, malaria, and diphtheria, on isolated cases, and on medical subjects. The book ends with a pleasantly written description of a Scottish women's hospital in Macedonia.

## JOURNALS.

JOURNAL OF PATHOLOGY AND BACTERIOLOGY. Vol. XXIX., No. 2. April, 1926. Pp. 141–221.—*The Occurrence of Brucella abortus and Mycobacterium tuberculosis in Cows' Milk*, by G. S. Wilson and M. M. Nutt (Manchester). Samples of Manchester milk contain *B. abortus* in 8 per cent. and tubercle bacilli in 18 per cent.—*On Bacterial Variation with Special Reference to the Alleged Convergent Phenomena Exhibited by Certain Distinct Pathogenic Species (B. typhosus and B. enteritidis Gaertner)*, by A. N. Goyle (London). A thorough study of the serological relationships of the various forms of typhoid and Gaertner bacilli which, in some respects, show a curious overlapping.—*A Reticle of Endothelial Cells in the Thyroid and Parathyroid*, by G. S. Williamson and I. H. Pearse (London). The endothelial system of the thyroid contains many large granular cells resembling tissue mast cells; their abundance and cytoplasmic structure vary with states of functional activity.—*Heterologous Cancer Grafts*, by J. Gheorghiu (Brussels and London). Mouse cancers will grow for a while in new-born rats and may be so propagated for as many as 20 passages extending over more than a year. But the tumours never lose their species-specific character nor will they grow in adult rats.—*The Influence of Thyroid Feeding on the Islets of Langerhans in the Guinea-pig*, by G. R. Cameron (Melbourne). Causes hypertrophy of pancreas and a more than proportional increase of islet tissue.—*An Epidemic*

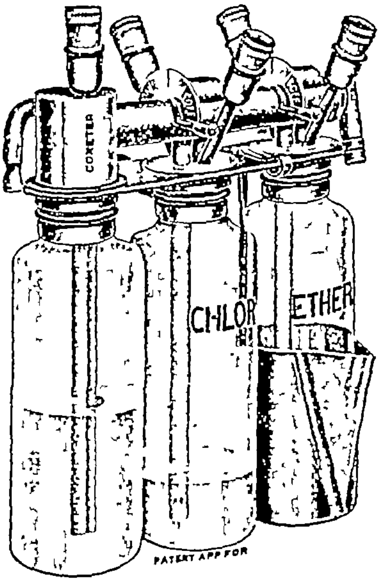
Affecting Stock Rabbits, by G. R. Cameron and F. E. Williams (Melbourne). An epidemic of suppurative lesions about the head and neck due to an organism similar or identical to those described by Schmorl and Beattie.—Arthritic Muscular Atrophy: the Oxygen Consumption of Atrophied Muscles, by A. E. B. Harding (London). Muscles wasted in sequence to an experimental arthritis use more oxygen than normal muscles and more than muscles wasted from simple disuse.—"Calcification" in the Rabbit's Brain, by C. Da Fano and J. R. Perdrau (London). In two animals inoculated with encephalitic material changes were found similar to those known in human brains as "calcification," though the abnormal deposit seems to be mostly composed of iron salts.—The Four Human Blood Groups, with Special Reference to their Agglutination Titres and to Abnormal Donors, by A. R. Jones and E. E. Glynn (Liverpool). A careful quantitative study of iso-agglutinins in 40 persons. Titres vary widely and need consideration in transfusion; thus the serum of a "universal donor" may agglutinate so strongly as to cause trouble when it is diluted in the circulation of the recipient. Seven examples of abnormal agglutination were found.—Bacterial Contamination of Commercial Peptone, by H. D. Wright (London). Some examples of peptone contain so many dead bacteria that they may be easily found microscopically in broths made with them.

JOURNAL OF INDUSTRIAL HYGIENE, March, 1926.—R. J. DeMotte, speaking from his experience, maintains the thesis that antiseptics should have little to do with the treatment of accidental wounds which are disinfected by Nature's own antiseptics, the blood and serum. Rational treatment should consist in helping nature with mechanical measures which are outlined.—The chief contribution in this number deals with lead poisoning among oxyacetylene welders employed in scrapping naval vessels. The trouble is one which has arisen also in this country. Detailed statistics are given which exhibit for an average personnel of 73 men an average of 253 working days lost per month as a result of plumbism; the shortest period of exposure was seven days and the longest 2·4 months, but the men for the most part were newly employed at this work. Hence, symptoms of chronic lead poisoning were not to be expected. Clinical findings are quoted of which the absence of hypertension is the main point worth recording. The poison was absorbed by breathing lead fumes generated when the hot flame was brought to bear on old paint on the ships' plates. Preventive measures are particularly difficult to install.——April, 1926.—A statistical study of occupational diseases reported in the State of Ohio is given by E. R. Hayhurst and D. J. Kindel. It is concerned with 3226 cases notified by doctors under legal obligation during five years ending June 30th, 1925. The list, which includes all eligible for compensation diseases, and some others, is far wider than that of our Factory Act. Dermatoses account for 2264 cases, lead poisoning for 431, and benzol and its derivatives for 55. The rubber industry is responsible for nearly all the dermatoses which are separately tabulated by the process concerned. The lead poisoning cases also are separately tabulated; the manufacture of storage batteries accounts for 145 cases, painting motor-cars for 114, and the manufacture of white lead for 54. Information is given as to the age-distribution of these cases. The authors note that an increase has taken place both in the number and range of occupational diseases, and conclude that one of the most profitable investments in the entire industrial field is the control of industrial health.—L. T. Fairhall considers the estimation of zinc in organic matter, and points out how quantities of zinc ranging in amount from 0·002 mg. to 50 mg. can be satisfactorily estimated within 5 per cent. of the amount actually present.—R. T. Lutz reviews the literature of the occurrence of zinc in tissues and presents a study of its normal distribution in the rat, cat, and man. He considers that traces of zinc in animal tissues are normal and universal, since this metal was found present in every sample analysed. He puts forward as a probable hypothesis that, in any given tissue of an animal species, there is a definite normal concentration of zinc which is constant within a small range. This article contains much detailed information given in tabular form.

# New Inventions.

## AN IMPROVED ANÆSTHETIC APPARATUS.

THE accompanying illustration depicts the latest improvements in this machine. The water sight feed for mixing the $N_2O$ and O of the new set of triple bottles is substantially the same as it has always been, but the mounts for the ether and chloroform bottles are worked on a different and, I think, an improved principle. They are called the "1926 type," and are also made with twin bottles where one is not required for chloroform. In place of the two levers of the older type, one for "on" and "off" and the other for the degree of saturation required, I now have one lever only which, when moved over a semi-circular scale, causes the gases to go either through a by-pass or partly through the by-pass and partly into the anæsthetic, or entirely through the anæsthetic as required. By setting the lever to such a position that only a fraction of the gases bubble out of a small hole drilled near the bottom of the long tube in the anæsthetic bottle, a very lean mixture is obtainable, and on the other hand, even with a full flow and a high pressure, leakage is negligible. This new arrangement of levers enables one to regulate the amount of ether or chloroform with far greater accuracy than was possible formerly. For those who want to use a large quantity of ether, there is provided a hot-water cup to enclose the ether bottle as a precaution against freezing. The lamp to prevent the gas from freezing, which was always a source of danger, has been omitted. This has been rendered possible because the makers now provide non-freezing gas, but in any case I find that a small hot-water bottle placed on the side of the reducing valve of the gas bottle prevents freezing and enables one to get a steady flow of $N_2O$.



I have to acknowledge my great indebtedness to Mr. Wellesley, of Coxeter and Son, Ltd., for producing such an excellent method of controlling the small amount of ether or chloroform that is used.

functorily applied than if it is carried out as thoroughly as such things can be done on the large scale. That the later doctrine has its disciples in Germany is indicated by a recent article[1] by Dr. W. RIMPAU, director of the Bacteriological Institute in Munich, who quotes CHAPIN with approval, while he advocates instruction of school-children in the objects and methods of concurrent disinfection of articles soiled by the infective patient. The public health officer in this country must, of course, anticipate opposition from the people to any departure from a measure on which they have been taught by his predecessors to place reliance. When an outbreak of infectious disease occurs in connexion, for instance, with a school, drains and disinfection are the first things that occur to the minds not only of the parents but even of the teachers. The unorthodox official must take the risk that an epidemic, for some imperfectly understood reason, may follow the inception of his new policy and the coincidence be mistaken for effect. Nevertheless, it is imperative to educate a public which is not likely to accept the modern method of preventing diphtheria and scarlet fever by active immunisation so long as it is allowed to believe that spraying and fumigation of schools and the liberal use of disinfectants at home are a real safeguard against casual infection. Their enlightenment is a function not of the health officer but of the whole medical profession.

It should be our concern, however, to watch that the pendulum is not allowed to swing too far in the opposite direction. Prof. RIMPAU suggests that the established value of certain means of disinfection under specific conditions should be brought even more prominently before the people than is done at present. To this end we commend to practitioners Prof. H. R. KENWOOD'S article in our present issue (p. 1055). He is a firm believer in the value of disinfection scientifically applied, and his laboratory and field experiments enable him to speak with authority on the relative potency of various disinfectants as well as the conditions most favourable to their action. The present revision of ideas among health officers is reflected, too, in a tendency to question the advantage of wholesale hospital isolation for scarlet fever which may lead to an increase in the home treatment of these diseases. Under such conditions, it is agreed that assiduous concurrent disinfection, however simple in character, is required. The information conveyed in Prof. KENWOOD'S paper should be of real value for this purpose. Finally, it should be made quite clear that the failure of disinfection to stop the spread of air-borne infections does not belittle the part it has taken in the suppression of the diseases communicated by the alimentary route or by inoculation. Just at the moment when fumigation is regarded by most sanitarians as the form of disinfection which can most safely be discarded, its use is being extended for the destruction of vermin, especially on board vessels. It is our strongest weapon against the rat and the flea, and its importance is commensurate with the world prevalence of plague. The port sanitary officer who has to deal rapidly with the holds and crews' quarters of vessels infested with all sorts of parasites retains his respect for fumigation. As in other applications of science, it is only the blind routine of its use on a large scale which has brought discredit on a measure which is of immense value when used at the right time, in the right place, and in relation to the medium of infection to which it is properly applicable.

## THE PRECANCEROUS STATE.

THE precancerous state has recently received a good deal of attention. It has been the subject of a discussion in the Section of Surgery of the Royal Society of Medicine.[1] Sir LENTHAL CHEATLE, who for many years made this problem, as applied to the breast, his special study, has published another paper on it under the title Desquamative and Dysgenetic Epithelial Hyperplasias in the Breast.[2] Prof. HORST OERTEL, of Montreal, has discussed it in an address on Involutionary Changes in Prostate and Female Breast in Relation to Cancer Development.[3]

The difficulty of the problem begins with the definition. Dr. J. H. SEQUEIRA, who opened the discussion at the Royal Society of Medicine, began with the statement: "I find it a little difficult to define exactly what is a 'precancerous' condition, although I think we are all aware of what is generally understood by that term." CHEATLE expresses himself in equally diplomatic terms. In describing a certain form of what he terms "dysgenetic epithelial hyperplasias," he states that it is histologically more nearly connected with a condition of early carcinoma than any other pathological process in the breast and that it, therefore, represents the "precancerous" condition. But, he adds, "I would lay it down as a law that there is no kind of epithelial hyperplasia that will inevitably end in carcinoma." His views on this subject demand special respect because they are based on a study of sections of the whole breast. In this way he has been able to collect unique material and to observe the earliest hyperplastic changes, occurring sometimes only in a single duct. He correlates the various changes in a sequence of events which begins with what he terms a desquamative epithelial hyperplasia. The next change is a condition of dysgenetic epithelial hyperplasia in which the epithelial cells retain their normal structure. In that stage they frequently produce papillomata confined within the acini and terminal duct. This stage is followed by the precancerous state in which the individual cells show signs of beginning malignancy—nuclear hyperchromatosis, variation in size of cells and mitoses. In this state the hyperplastic changes are still confined within the ducts and terminal acini. When it extends beyond these and invades the surrounding connective tissue the development of carcinoma has been reached. Sometimes the precancerous state may be seen in the centre of a fully developed carcinoma. CHEATLE points out that these various hyperplastic changes find a complete parallel in the changes seen in the skin of mice subjected to tar painting. These contentions are illustrated by numerous clear figures accompanying the paper. OERTEL, on the other hand, looks upon these hyperplastic changes, which he has studied in breast and prostate, as regressive changes accompanying the physiological involution of these organs. Morphologically they may give the appearance of malignant new growths so completely that he has frequently diagnosed them in the past as "early cancer" or at least as "suspicious of early cancer." But the frequency with which such conditions occur in the two organs during the regressive periods of life leads him now to believe that they are only potentially cancerous and require yet an additional factor to elicit malignancy. Following BORST, he prefers the term "carcinoid" to the term "precancerous." His statement of the great frequency with which such hyperplastic changes occur in the senile prostate finds confirmation in a recent paper by NELLER and NEUBÜRGER[4] who discovered them in approximately every fourth senile prostate.

The problem of the precancerous state is obviously intimately bound up with that of the ætiology of cancer. The search for a precancerous state follows naturally from the conception of cancer as a biological cellular change. If cancer is the expression of some change in the internal structure or metabolism of the cell, it is most probable that such a change would set in gradually as the result of a slow process occurring in the cell. This preparatory stage would then represent the precancerous state. But if we accept GYE's conception and look upon cancer as resulting from the entrance of a virus into a cell, then these hyperplastic conditions would merely represent one of possibly many conditions which predisposes a cell for the attack by the virus. If the virus is not present they will never develop into cancer. On the other hand, it is conceivable on this view that cancer may arise without being preceded by any of these hyperplastic changes. The problem of the precancerous state is of more than academic interest, since the question naturally arises whether the presence of a precancerous condition does or does not call for operative removal. The possibility emphasised by OERTEL that the histological picture of a precancerous or carcinoid condition may be mistaken for an early carcinoma must be taken into consideration as a possible fallacy when claims are made of a cure of an early cancer. The final solution of the problem of what constitutes a precancerous state will have to wait upon further advance in our knowledge of the ætiology of cancer.

◆

## "B. C. G."

IN one of a series of American public addresses printed in our present issue, Sir ARTHUR NEWSHOLME considers the age-incidence of mortality from tuberculosis and shows that the risk of the acute form of the disease is greatest in the first two or three years of life. Hence arises the supreme importance of protecting young children from infection. Prof. A. CALMETTE has made a bid to protect these children by inoculating them, before infection can occur, with an attenuated living tubercle virus, and Dr. J. G. ADAMI, in an address, which also appears in this issue, describes CALMETTE's work as a magnificent advance, important for the prevention of both human and bovine tuberculosis. We have already referred[5] to the technique of this prophylactic vaccination, the results of which are now assembled in a monograph appearing in the February number of the *Annales de l'Institut Pasteur* and in the *Revue de la Tuberculose* of the same month. As long ago as 1909 CALMETTE described a strain of tubercle bacillus grown on glycerinated ox bile and now known shortly as B.C.G. (Bacille Calmette-Guérin). The microbiological properties of this strain have nowhere been set out exactly, but it is presumed that CALMETTE and GUÉRIN have used throughout the virulent bovine strain designated *lait de Nocard*.[6] B.C.G. was subcultured 230 times up to January, 1921, the date at which the vaccination experiments were started. It was then incapable of producing tubercles, either by intravenous, intraperitoneal, or subcutaneous inoculation or even by ingestion. The cultures resembled those of glanders in appearance, and massive infection in calves caused a general disease resembling typhoid fever which cleared up spontaneously after 15–20 days of fever without producing the slightest tubercle formation, as proved by subsequent autopsy of the animals.[7] In preparing the vaccine, B C.G is now cultivated on potato and glycerinated veal broth, or on Sauton's asparagin medium The cultures should not be more than ten days old, or, the authors state, they will contain too many dead bacilli. The vaccine is administered in milk at body temperature in three doses and is harmless, giving rise to no digestive trouble or malaise even in new born infants It can be obtained ready for use from the Pasteur Institute in Paris.

[5] THE LANCET, 1925, i., 1352 and 1303.

[6] Annales de l'Institut Pasteur, 1924, xxxviii., 371.

B C G vaccine has been tested by Calmette and his co workers on an extensive scale in rabbits and guinea pigs, a partial immunity being obtained lasting for six months. In calves the vaccination was found to be successful only in animals under the age of 15 days, prophylaxis was obtained by a single injection of 50–100 million organisms and was found to last for about 12 months. The number of calves thus immunised up to the end of 1925 was 3051, and the authors state that the growth of these animals has been satisfactory and that no harmful results followed the vaccination. Experiments on higher apes made by Wilbert in 1923 and 1924 suggested that B C G vaccine affords protection at all ages against infection from cohabitation with animals experimentally infected with tubercle. Wilbert[8] who conducted these experiments on behalf of Calmette, tested 15 chimpanzees and 59 other apes. In the case of the former three were vaccinated with B C G, five were infected with virulent cultures, and seven were retained as controls. These experiments were started in February, 1924 The five infected animals died quickly from tuberculosis as did also four of the controls, the remaining three controls succumbing to an accidental infection of bacillary dysentery The three vaccinated chimpanzees were alive and well in June, 1925. Of the 59 other apes 19 were vaccinated with B C G, 20 were infected with virulent cultures of tubercle bacillus, and 20 retained as controls. Among the 19 vaccinated animals (between September, 1923, and February, 1924) 6 remained alive and well in June, 1925, the other 13 having apparently died of accidental infections and trauma Of the 20 infected animals 19 died meanwhile of tuberculosis, whilst of the 20 controls a similar number also succumbed to tuberculosis.

In 1921 Calmette and his co workers proceeded to vaccinate new born infants by this method, and up to the end of 1925 had treated 1317 infants. The results are divided into two groups: (1) 564 cases (of which 231 had been in contact with tuberculous cases) under observation for 12–18 months, of whom only two are known to have died of tuberculosis and 43 of other diseases, (2) 753 cases (of which 355 had been in contact with tuberculous cases) under observation for 6–12 months, of whom 9 are known to have died of tuberculosis and 53 of other diseases. It would have been easier for others to assess the value of these figures if they had been returned as numbers of children alive or dead at three separate age periods—e g, 6 12, and 18 months. The age at death of the 11 infants (taking the two groups together) who died of tuberculosis, was under 6 months in all cases but one The figures, therefore, show that of 1317 cases vaccinated 10 had died of tuberculosis by the end of the first six months. It would be unwise to draw further deductions since there is, obviously, a difference of six months between the youngest and oldest infant in each of these two groups. The infants vaccinated have been kept under observation, and where their environment proved to be unsatisfactory they have been boarded out, but the statistics given do not show the proportion of children thus removed from their homes This omission makes it difficult to compare the figures with those for an ordinary infant population. There is a further difficulty in that the death rate from tuberculosis in infants in the normal population of France is not given, although Calmette states that in the case of infants born of tuberculous parents and placed with healthy foster-mothers shortly after birth the mortality from tuberculosis is approximately 7 per cent. in the first year Finally, this method of prophylactic vaccination has been applied to 3352 infants and 931 adults among the endogenous population of French colonies. It is evident that Calmette and his co workers have carried out an important and extensive sociological experiment on bacteriological lines, of which the ultimate results will be awaited with much interest. At the present moment the data are too vague and lacking in controls and the period of the experiment too short for anything like a final judgment.

## PROTECTION FROM THE PHOTOGRAPHER

On Tuesday next, June 1st, there will come into operation a beneficent enactment whereby medical practitioners who are called upon to give evidence in *causes célèbres* will be protected from the risk of a form of publicity which they sometimes encounter but seldom enjoy The new law makes it an offence, punishable summarily by fine not exceeding £50, to photograph in any court any person who is either a judge or a juror or a witness or one of the parties in the case Sketching or any other kind of portraiture attempted in court with a view to publication is similarly prohibited, as is also the actual publication of any such photograph taken or sketch made in contravention of the new interdict. Although these provisions occur in a statute called the Criminal Justice Act (which otherwise deals mainly with criminal procedure at assizes and quarter sessions and before the magistrates), they extend to all sorts of courts, civil as well as criminal. "Court" means any court of justice and includes a coroner's court; "judge" includes a coroner Finally, photographing or sketching is deemed to occur in court if it takes place within the precincts of the court buildings or if the victim is photographed while entering or leaving the court room or the precincts of the building The new provision will not, of course, prevent the publication of studio portraits of medical practitioners who happen to be witnesses in some case which attracts public attention. The battery of press photographers, however, often to be seen outside a court house on the morning of some sensational trial will have its guns spiked—unless, indeed, it is still permitted to photograph barristers and solicitors to whom Parliament does not seem to have given the same measure of protection

**Alexandra Day.**—The date of Alexandra Day has been postponed from June 9th to June 30th. The organising committee is in urgent need of assistance and would welcome helpers in depôts, rose sellers and the loan of motor cars on June 28th, 29th, and 30th. Money collected on Alexandra Day is distributed amongst hospitals and charities for the sick. Anyone who will help should write to Miss C. M Beeman, 33, The Grove, The Boltons, London, S W 10

# Annotations.

"Ne quid nimis."

## MUNICIPAL CONSULTING OBSTETRICIANS.

THE Metropolitan Borough of Hampstead recently invited applications for the new posts of consulting obstetrician, several of whom are to be appointed as the outcome of a recommendation by a special medical subcommittee. The infantile mortality-rate of the borough is already low—56 per 1000 births in 1924; the maternal death-rate has been reduced to about 3 per 1000 births, the general death-rate being 11 per 1000 of the population. Still further reduction in maternal and infantile death-rate is, however, aimed at, and to this end a subcommittee, consisting of three medical members of the Maternity and Child Welfare Committee, with a lay chairman, was appointed in 1923, the reference being the investigation of the deaths of infants under 2 years of age, of still-births, and of maternal deaths. A comprehensive inquiry was made into the circumstances of 83 infantile deaths, 3 maternal deaths, and 26 still-births notified in 1924; in his annual report for that year Dr. F. E. Scrase, the medical officer of health, notes how friendly and helpful were the replies of local practitioners to a circular letter inviting opinions as to the causes of the still-births occurring in their practice, and suggestions as to the prevention of these in the future. The most important recommendation of the medical subcommittee which sifted the evidence obtained was that in difficult cases the services of a skilled obstetrician should be available to supplement those of the practitioner, and this recommendation is now being carried into effect. Five experts have now been appointed in the persons of Miss M. Basden, Mr. A. O. Gray, Mr. C. S. Lane-Roberts, Dr. S. G. Luker, Mr. L. C. Rivett. They are not to be called in by midwives direct, but are to be at the disposal of practitioners in cases of grave difficulty. Their guaranteed fee of five guineas per case will not vary whatever the services rendered; this fee is recoverable in whole or in part from the patient at the discretion of the borough council. It is anticipated that beds may be available, but in this respect the scheme has yet to be elaborated. We congratulate the borough of Hampstead on a wise endeavour to attack the problem from both ends, since pari passu with this emergency organisation antenatal vigilance is to be still further pursued. Many of Dr. Scrase's colleagues assume that the elaboration of facilities for examination of prospective mothers is all that is needed to prevent difficult or at any rate disastrous labours. Of recent years the value of preventive measures such as antenatal examination has, perhaps, been overstressed, for the methods available for estimating in advance the relative sizes of the full-term child and of the pelvis are still far from perfect. However carefully the patients' histories and measurements may have been taken, a certain proportion will surprise the midwife at the time of labour and perplex if not alarm the doctor summoned to her help. It is in these cases where skilled manipulation by one who is constantly dealing with similar emergencies may save the mother at least from severe laceration and the child from probable death. The very fact that an expert may be summoned at need will give the practitioner confidence, and the success of the experiment will certainly not be measurable by the number of times that the consultants are called in. It seems to us likely that other local authorities will find it expedient to follow the example set by Hampstead in this matter.

## PSYCHOTHERAPY IN UROLOGY.

IN a recent number of the *Medizinische Klinik* (Jan. 9th, 1926) Dr. J. J. Stutzin puts forward an interesting point of view in his article on Psychotherapy in Urology. Monumental work has been done in the past forty years in various branches of science, and corresponding advances in the treatment of disease have followed, but a doubt has come to Dr. Stutzin as to whether, in the general striving after perfection of methods and technique, the personality of the patient is not being neglected. Beginning with a short disquisition on our present knowledge of the sympathetic and parasympathetic nervous systems, he points out that they are very much bound up with the mental state of the individual, and that the emotions, therefore, have a direct bearing on the tone and action of the viscera, which are controlled by the so-called vegetative centres. Again, there is a constant play of reflexes between the voluntary and involuntary systems, as witnessed by the rigidity of the abdominal muscles, which may be caused by an inflamed intestine, and the cardiac palpitation brought on by fright. Even before this was fully understood various attempts, more or less empirical, were made to treat disease by psychotherapy. The writer divides these methods into two groups: "diversion," including suggestion, auto-suggestion and hypnotism, and "disinfection"—namely, psycho-analysis. Of these, he considers psycho-analysis unproductive as compared with the time it takes, and hypnotism unjustifiable in view of the inroads it makes on the individuality of the patient. He confines himself, then, to suggestion. Passing on to the special subject of urology, Dr. Stutzin points out that no single organ or system of organs can be considered apart from the rest of the individual. For the sake of convenience a specialty may be created, but this is hardly a biological one. The urinary tract, being so closely associated with the generative system, is peculiarly liable to be affected by emotional disturbances. The urologist is primarily a craftsman; his pre-occupation is mainly surgical, and, although he may keep an open mind on speculative questions, yet his line of treatment is always practical. It is not suggested that the treatment of organic lesions may be neglected. The first thing to be decided is whether such a condition exists and, if so, whether it can be held responsible for the whole symptom-complex, or whether some psychic influence is at work as well. If no material cause is detected we are faced with the question: Can the clinical picture be fully explained by an emotional cause, or must there be some yet undiagnosed organic basis? This is where the fully-trained doctor, who is able to recognise a pathological condition, has the advantage over the lay practitioner of suggestion, who may perhaps bring a well-arranged scheme of treatment by suggestion and a thoughtful personality to bear on some disease which has no chance of alleviation by such means. Recent work tends to show that, although the secretory system is not under the control of the voluntary centres, it can be subjected to direct influences. Heilig, of Vienna, has proved in a long series of cases that, in the hypnotic state, painful sensations cause polyuria, and pleasurable ones oliguria; and, as the result of these and other observations, sundry operations on the nerves of the renal hilum have been devised. The operators, however, are apt to forget that the sympathetic system is far too complicated and delicate a structure to be coerced in this way, and the results, though they may be good at the time, are apt to be bitterly disappointing to the patient in the long run. A similar experience is that of Glaser, of Berlin, who reports cases of bronchial asthma, intractable after phrenicotomy, which have yielded to suggestive treatment. Dr. Stutzin cites various cases in which alarming symptoms, such as severe renal hæmorrhage and renal colic, were proved by exhaustive examination to have been brought on by mental states, analogous to the way in which certain fakirs can by the exercise of will power prevent or cause the escape of blood from a wound.

Furthermore, these cases have been cured by treatment of the mental state. The bladder, the ultimate nature of whose nervous mechanism and musculature has not yet been worked out, is very greatly affected by the emotions, as witness its irritability under the stress of nervous conditions; a clinical manifestation of this irritability is nocturnal enuresis. Dr. Stutzin does not make any exaggerated claims for his methods, but rather puts forward a plea for a broad outlook in diagnosis and treatment.

## INSURANCE OF PROPERTY AND CIVIL DISTURBANCE.

THE cars of many of our readers are insured through the Medical Insurance Agency under the Doctors' Special H.P. Motor Policy (Lloyds). In Section 2 of this policy, under the heading Accidental Damage, it is stated that the underwriters shall not be liable for wear and tear, or depreciation or mechanical breakdown, but shall indemnify the insured in respect of damage caused by collision with any other object, resulting from wear and tear or mechanical breakdown, and shall also indemnify the insured in respect of external damage to the insured car wilfully caused by employees during elections or during riots or civil commotions. It was stated by the Medical Insurance Agency, in a letter which we published last week, that this policy covers any damage that may be done to the holder's car during any civil disturbance, including such acts on the part of strikers as removal of carburettor, slashing of tyres, puncture of petrol tank, &c., or damage caused by stones thrown at car. It is not necessary to procure these benefits that the car shall be labelled "Doctor's Car," though where a car is being used only for professional purposes such a label would seem advisable. If a car is not used for its normal purpose the policy will be invalidated unless previous notice has been given and the assent of the underwriters obtained. For example, a private car is not normally used for the conveyance mainly of foodstuffs, but a four-seater car could carry four passengers even though they be not personally known to the owner and the policy would remain in full force. Damage to springs due to overloading is not covered under the policy whatever the cause of the overloading may be. The Medical Insurance Agency also informs us that the holders of the "Comprehensive" Household Policies of the type issued through the Agency are covered for damage by riots and civil commotions. This is not necessarily true of holders of fire and burglary policies or "combined" household policies.

## FROIN'S SYNDROME.

IN 1903 Froin described a group of signs in the cerebro-spinal fluid which has come to be known as Froin's syndrome; the signs were yellow colour, massive coagulation of the fluid in the tube or even in the needle, and the presence of a large number of cells. This group of changes has excited much interest among clinical neuropathologists, and many of them have desired to modify it in some way; thus, the combination of yellow colour and massive coagulation, regardless of the number of cells, often goes by Froin's name, and Greenfield and Carmichael[1] wish to apply the term syndrome of Froin to fluids which contain 0·5 per cent. or more of protein, whether spontaneous coagulation occurs or not, and whether the fluid is xanthochromic or not. The diseases with which the syndrome is associated are, except in rare instances, conditions involving spinal compression, and when the complete syndrome has been found the compression has usually been due to syphilitic pachymeningitis. The current number of *Minnesota Medicine*[2] contains an important article by Dr. Gordon Kammon, in which the history of the subject is reviewed and four cases are described in which Froin's syndrome or a modified form of it was found. It is a curious fact that while to-day the presence of Froin's syndrome is always considered suggestive of a spinal tumour, none of Froin's original cases were tumours; one was a case of meningo-myelitis, another had multiple tuberculous foci in the bones, and the third was a case of ascending or Landry's paralysis. After Froin's observations other cases were soon reported, and by 1908 Sicard and Descamps went so far as to say that the syndrome always meant meningitis. During the next year, however, Blanchetiere and Lejonne found the same type of fluid, but without increase of cells, in a case of intramedullary spinal tumour, and this was soon followed by Nonne's observation that cord tumours are associated in general with a pronounced increase in the globulin content of the fluid in the lumbar cul-de-sac, without, as a rule, any change of colour or cell increase. Mestrezat considered that two factors were necessary for the production of Froin's syndrome, separation of the fluid in the lumbar space from the rest of the subarachnoid space, and engorgement of the veins or inflammation of the walls of the vessels below the site of blockage. Ayer brought about the syndrome in cats by causing extradural pressure on the cord by means of paraffin. In 1923 Cushing and Ayer reported five cases in which xanthochromia with the occurrence of a spontaneous coagulum was found in the fluid *above* tumours of the cauda equina, and in the next year Hammes also recorded a case of this type. In view of these observations the theory that loculation plays any essential part in producing Froin's syndrome is no longer tenable; Cushing and Ayer differ in their opinions as to its actual cause, the former holding that it is produced by a transudation into the fluid from the tumour itself, while the latter ascribes it to transudation from engorged veins in the spinal canal. Considering the variety of conditions other than tumours—polyneuritis, tuberculous meningitis, poliomyelitis—in which the syndrome has been found Ayer's theory is the more acceptable. Dr. Kammon does not seem to have been acquainted with a very important and comprehensive article by Greenfield[3] on this same subject.

## HEALTH CERTIFICATES BEFORE MARRIAGE.

THE Royal Institute of Public Health, in session at Bristol last week-end, gave consideration to the advisability of a health certificate before marriage. In the May number of the *World's Health* Dr. Leopold Bard, of Buenos Aires, discusses the Bill dealing with this subject which is now before the Argentine Chamber of Deputies. In his opinion, venereal disease (except tertiary syphilis, and sometimes even tertiary syphilis) should constitute a temporary bar to marriage. What are likely to be the consequences of a marriage when the husband is suffering from venereal disease?—illness, disablement, still-births, poverty, unhappiness, or the bearing of degenerate offspring. One or all of these must be reckoned with. Just as the law provides a penalty for infanticide, so, thinks Dr. Bard, should it punish the spread of venereal disease through marriage. The proposed Bill provides that any man desiring to marry must, during the fortnight preceding the registration of his intended marriage, undergo a medical examination and provide himself with a certificate stating that he is free from venereal disease. This certificate must be furnished by a recognised physician. Provision for medical examination is made by the establishment at the National Public Health Office in the capital of a special bureau for the delivery of pre-matrimonial certificates. In villages or other remote places the certificates may be given by the local medical officer of health. No marriage will be regist[illegible] without previous examination of the male part[illegible] and without production of a certificate sta[illegible]e is free from venereal disease. Any official delivering a marriage form without first demanding presentation of the medical certificate will be liable to punishment by imprisonment, and any physician knowingly making a false statement upon the certificate will be deprived of the right of exercising his profession in any part of the Republic for a period of three years. It will be interesting to see whether public opinion in the Argentine Republic is sufficiently awakened to the dangers of venereal disease for such a drastic measure to become law. The introduction of health certificates before marriage cannot be regarded as purely a health measure, for it touches a grave sociological problem. The institution of marriage is none too stable at the present day. Some may question the wisdom of placing new difficulties in the way of a legal union. May not this formality, slight though it may seem, be sufficient sometimes to tip the scale in favour of an illegal union, undesirable, as experience has shown us, both from the health and social standpoints? Suppose a young man is suffering from a venereal disease. If he has a social conscience he will undergo treatment before marriage. If he has no conscience he may evade the difficulty of a medical examination by contracting an illegal union. If, on the other hand, he be free from venereal disease, the health certificate before marriage is a useless formality. There is, however, this consideration in favour of such a certificate. Many public health workers are agreed that compulsory periodic medical examinations, if introduced, would contribute more than any other measure to the prevention of disease. The marriage certificate would constitute as valuable an index to the health of young men as the army medical examination which showed us up as a C 3 nation. Is it desirable, however, to link up a health measure with a basic social institution such as marriage?

## DIGESTIVE ANAPHYLAXIS.

THE problems of human idiosyncrasy and tolerance have troubled clinicians from time immemorial, and the discovery by Charles Richet of the principle of anaphylaxis marked a distinct step towards their solution. In his earlier experiments he induced the reaction by intravenous injection but, since in practice the offending substances reach the system almost entirely by the mouth, it is "digestive anaphylaxis" which presents the really urgent clinical problem. Few besides those who have given special attention to the subject realise how long the list of possible causes and possible symptoms of this anaphylactic reaction is becoming. Even white wine, which no one would suspect of containing protein, is not guiltless,[1] and Bolten[2] shows that attacks of Czerny's disease and of dysmenorrhœa can both be released by anaphylactic shock. Sir Maurice Craig[3] has shown that certain forms of idiopathic epilepsy also depend on protein sensitivity, and, in fact, it seems probable that any kind of vago-sympathetic disturbance may be excited in this way. Arloing, Langeron, and Spassitch, whose previous work is well known, now set forth[4] the results of an extensive series of experiments on guinea-pigs, with the twofold object of increasing their sum of knowledge of the working of the phenomenon and of discovering the best defence against it. They employed two groups of antigens, one of unmodified substances such as horse serum, boiled cow's milk, olive oil, and solutions of glucose, quinine, and antipyrine, and a larger group composed of products of the artificial digestion of proteins, prepared for them by a well-known firm of manufacturing chemists. This was to eliminate the indigestion factor which is well known to produce anaphylactic reactions apart from the nature of the ingested substance. The latter group included beef, pork, casein, white of egg, fresh-water and sea fish, crab, mussel, and dried peas—all substances known to cause urticaria in human beings. The stock diet was two parts bran and one part hay, and the sensitising meal consisted of 3 c.cm. of peptone solution or 0·3 g. of unmodified substance. This was given on eight consecutive days, and then stopped for a period of 12 to 17 days to allow incubation. Now, the normal organism is protected against digestive anaphylaxis by two mechanisms: the mucosa of the small intestine, which will not allow the intact albuminoid molecule to penetrate it, and the liver, which acts as a barrier against protein. In order, therefore, to make sure of obtaining their reactions, the authors added to the meal small quantities of foreign (ox) bile which has the temporary effect of so altering the histological composition of the mucosa as to allow albumin to pass through it. After a certain amount of repeated anaphylactic shock, the whole of the liver begins to undergo necrosis and to lose its power of protecting the system against proteins. It has already been recognised that many anaphylactic reactions occur after enteritis or vague intestinal trouble, which would have the effect of making the mucosa penetrable.

The guinea-pig is regarded by the authors as a good subject for these experiments, for its behaviour gives ample evidence of the strength of the reaction. They relied on this alone, without testing for the hæmoclastic crisis, which might be affected by other causes. Pruritus, which always appeared, they considered a particularly good quantitative indication. No animal ever manifested convulsions. The syndromes produced were acute digestive anaphylaxis, primary protein shock (without previous sensitisation), anaphylaxis to proteins, fats, carbohydrates and crystalloids, and chronic digestive anaphylaxis. The order of the activity of the proteins was found to be as follows: crab, serum, casein, milk; then, less active, white of egg, beef, pork, skate, mussel, perch. Vegetable proteins had only a feeble action. Olive oil, besides giving a reaction of its own, would release a shock in animals sensitised by other substances. Antipyrine produced a stronger reaction than quinine, and a severe pruritus, a phenomenon not uncommonly seen clinically. Many animals suffered from asthma, and the authors claim that their results here and in the clinic prove the existence of an "épine respiratoire." An interesting conclusion which they draw from the results of administering horse serum, to which the animals could obviously not have acquired sensitivity, is that there is no essential difference between primary protein shock and the anaphylactic reaction. Both show a state of sensitivity, and whether this is innate or acquired is immaterial. Once the sensitivity is established, every dose of the appropriate antigen will produce a reaction, but after about three months their strength diminishes until finally they disappear; the intestinal mucosa has become immune. If, however, the meals are continued for a few more weeks, the attacks return, the reason being that the foreign substance ultimately creates lesions in the intestine and liver that constitute breaches of the natural protective barrier. The anaphylaxis is then chronic. The action of these proteins is not specific, and one will often release where another has sensitised. The severity of the reaction depends on the potency of the releasing protein. Hunger increases the reaction, and tuberculous lesions of the lung tend to force it into a respiratory form. For protection a single minimum dose, or several small doses of any protein, will give a temporary unspecific "sceptophylaxis." The intravenous method is the most effective. Prolonged administration will give first immunity, and then, after a period of months, desensitisation, and it is then possible to sensitise the animal afresh. In practice, in order to obtain immediate protection against accidents, a single dose of antigen will suffice, given by any method. If it is desired to create a more or less lasting immunity, frequent doses should be given of the particular protein to which the patient is sensitive by the path followed by the dose that caused the reaction.

Anaphylaxis has long been considered in the light of a curious accident. The Lyon school regards anaphylaxis, idiosyncrasy, and intolerance as essentially the same thing, and has greatly enlarged our conception of this class of phenomenon.

## RAT-BITE FEVER.

The bite of a rat infected with the specific spirillum may give rise to the curious chronic relapsing fever with certain general and local symptoms known as *sodoku* in Japan, where it is very common, or more generally as rat-bite fever. The wound caused by the bite of the infected rat heals quite normally but breaks down at the end of an incubation period of usually two to six weeks, the local condition becomes that of an acute inflammation, while general symptoms soon set in. The disease appears to be fairly widespread and has been reported in this country by T. J. Horder and others,[1] but although common in Japan it does not appear to have been often recorded in China until recently. The question of its prevalence in that country is beginning to attract considerable attention, however, and a case described this year[2] by Dr. E. S. Curtis, of Funing, Fukien, is of some interest. The patient was bitten on the right index finger and too vigorous home treatment resulted in gangrene of the skin of the affected finger. With fomentations and removal of the loosened skin the condition quickly healed up, but exactly 14 days after the bite the finger again became swollen and a gland appeared in the right axilla. The temperature rose to 101° F., the patient complained of pains all over, but with simple antipyretic remedies this quickly settled down and the local condition of the finger began to subside. Ten days later a similar flare-up occurred with some lymphangitis of the dorsum of the hand, and three purplish-red erythematous patches also appeared in this neighbourhood. This acute attack again subsided, but a third flare-up occurred a week later and a fourth a week after that. Each attack lasted about two days and they got progressively slighter, the fourth one being unaccompanied by any local exacerbation in the local condition of the finger. Following the fourth attack three small doses of "914" were given and no further attacks developed. This case appears to differ from the usual description in certain details. For example, the duration of the first attack—namely, two days—was very short as compared with the usual six or eight days. Again, the purplish-red papular rash appears only to have been represented by three spots on the affected hand. The spirillum was not observed in this case, but certain features suggest that possibly the disease in China is not of exactly the same nature as elsewhere and possibly due to a slightly different organism.

## SURGERY OF THE PHRENIC NERVE.

A brief account of the history of phrenicotomy and of the modern radical operation for ensuring hemidiaphragmatic paralysis has lately been published in the *Journal of the American Medical Association* (March 20th). The writer, W. H. Thearle, describes evulsion of the phrenic nerve as a minor and relatively simple procedure easily performed under local anæsthesia. The possible complications and accidents associated with the operation are, he says, relatively infrequent, but he repeats the warning given by Felix against completing the evulsion in far advanced cases with extensive pleural adhesions if cardiac or respiratory disturbances reach any degree of severity. Thearle's experience is in accord with that of other observers—namely, that cough and the bringing up of sputum are made easier by the hemiparalysis of the diaphragm. He issues a warning, however, against the independent use of phrenicotomy as a curative measure in advanced pulmonary tuberculosis, and his general conclusions are summarised in the statement that "radical phrenicotomy is especially advantageous in conjunction with artificial pneumothorax and extrapleural thoracoplasty, and is the primarily indicated surgical procedure in unilateral phthisis with predominantly basal lesions." Of 62 cases treated, 35 were operated on as an independent procedure; 50 per cent. of these were improved, and 10 per cent. markedly improved.

An interesting report of a case of persistent hiccough treated by injections of novocaine into the phrenic nerve appeared in the *Indian Medical Gazette* for March. The patient was a girl and her hiccough had persisted for nearly four months, by the end of which time even ice could not be retained, and she was in a state of profound exhaustion and suffered great pain in the region of the diaphragm. Other remedies having failed, D. M. Ghose, who reports the case, infiltrated the phrenic nerves with 2 to 4 c.cm. doses of a ½ to 1 per cent. solution of novocaine. Six injections were given once daily, and apparently on alternate sides. The hiccough subsided completely and eight months later there had been no relapse. Ghose used the technique of Krogh, inserting the needle two fingers-breadth above the clavicle close to the outer border of the sternomastoid muscle, and thrusting it vertically towards the scalenus anticus for a distance of 2 to 4 cm. (according to the amount of fat). When the nerve is reached the patient complains promptly, as a rule, of transitory pain in the shoulder and region of the heart, and sometimes also in the upper abdomen. Ghose states that perineural infiltration is adequate.

## A NEW TREATMENT FOR STROPHULUS.

The troublesome ailment of infants and young children up to the age of 6 years, alternatively known as lichen urticatus or strophulus, is generally believed to have a direct relation to errors of digestion. The crops of intensely irritable papules—often associated with diarrhœa, constipation, vomiting, or other gastro-intestinal symptom—recur indefinitely, and for no apparent reason, and are especially troublesome at night. Therapeutic measures include a revision of the dietary, administration of stomachics, aperients, lactate of calcium, and bicarbonate of soda, and a variety of baths and local applications. These remedies are all useful, but lay no claim to effect a cure. The frank physician counsels patience, and assures parents that eventually their child will grow out of the trouble. The *Paris Médical*, of April 24th contains the experience of Dr. Pasteur Vallery-Radot and Dr. Blamoutier in the treatment of lichen strophulus with peptone by the mouth, and if their claims should be confirmed this treatment marks a distinct advance in therapeutics. They state that of 20 cases treated and observed for periods of from three to ten months, 10 were cured by one or two courses of ten days each; 4 were cured after a month; 2 were cured in more than a month. Of the 4 remaining, 1 reported cured after a year's treatment, 1 in 15 months, and the other 2 were lost sight of. The method is very simple and obviously harmless, but the details, say the authors, must be very strictly carried out in every case. The first point in the instructions concerns the number of meals. In infants of about 1 year they must be reduced to four in the 24 hours—viz., at 8 A.M., noon, 4 P.M., and 8 P.M. Nothing, except small drinks of water, is allowed in the intervals. The diet may consist of milk, milky foods, purées of potato or French beans, peas, and lentils, bananas (which are always forbidden in England), orange juice, and compôtes of fruit. Older children take three meals only per day: at 8 A.M., 1 P.M., and 7 P.M. Their régime may include bread, biscuits, cakes, eggs, fish, meat (except pork) once daily, sweetbreads, soups, cauliflower, tomatoes, &c. Sweets, especially between meals, are strictly proscribed. The peptone is given exactly one hour before each meal and the granular form of the product will be found the best. The time must be conscientiously adhered to, for it is the most vital part of the treatment. The authors advise courses of ten days of administration followed by periods of five days' intermission. The treatment should not be immediately discontinued when a favourable result has been obtained. It is advisable to prolong it for a month or two after apparent cure, and to employ in succession (*a*) a simple meat product, (*b*) a bivalent, meat and fish combination, and (*c*) one containing a mixture of the peptones from meat, fish, eggs, and milk. The methods of manufacture and the source of the peptone are not indicated in the paper.

## LAMBLIASIS AND CHOLECYSTITIS.

A NEW society was founded in Italy last February under the title of "Society of Experimental Biology," with Prof. Giulio Fano, of the University of Rome, as its first president, and issues a bimensal bulletin. In the first number, published last April, Dr. C. Pappalardo,[1] of the University of Catania, describes experiments he made on five cases of cholecystitis in which he used the duodenal sound after the introduction of magnesium sulphate and examined the fluid thus extracted from the gall-bladder. In three of these cases he found mobile forms of lamblia intestinalis; in two of them van den Bergh's test was positive. The hypothesis that the parasites came from the duodenum rather than from the gall-bladder does not seem tenable, since the demonstration was conspicuous only in cases of cholecystitis and was wanting in other cases of gastric affections examined in the same way, and from the fact that the number of lamblia was approximately the same in the samples of bile A and B, while under the theory that the parasites came solely from the duodenum the first portions of liquid extracted should have shown them in greater abundance. Moreover, in view of the observation of Westphal, who in one case found lamblia even in the wall of the gall-bladder, it seems more than probable that in these cases also the parasite came from the gall-bladder. If this be admitted several possibilities suggest themselves: (1) lamblia can be the agent or one of the agents in causing cholecystitis; (2) lamblia may be an evidence of a condition favourable to the implantation of other germs, themselves the cause of the cholecystitis; (3) lamblia may be merely a harmless associate of the germs which produce the cholecystitis. The problem is a complex one and many interpretations of it are possible, but the fact remains of the noticeable frequency of lamblia in bile extracted by the duodenal sound in cases of cholecystitis and the possibility that it represents the only causal parasite. From a therapeutic point of view the cases showed the inefficacy of the usual remedies directed against lambliasis—i.e., stovarsol and repeated duodenal soundage.

## CARBON DIOXIDE IN EMPYEMA.

Carbon dioxide, inhaled in a concentration of about 5 per cent., is becoming recognised as a valuable respiratory stimulus, used especially to accelerate the pulmonary elimination of poisons or drugs, such as carbon monoxide, ether, and alcohol.[2] Since the healing of an empyema is dependent on obliteration of the cavity, the clinician uses every effort to promote expansion of the lung, which is often hampered in its restorative function by the organisation of exudate on the visceral pleura and by fibrosis within itself. In a recent article[3] Dr. E. D. Churchill, of Boston, discusses the methods at present in use for encouraging lung expansion; early ambulatory régime, deep-breathing exercises, blowing exercises, and other expiratory efforts against a partially closed glottis, relief of any respiratory pain by readjustment of the drainage-tube, or, where necessary, injecting or severing the intercostal nerve. Maintenance of a negative intrapleural pressure can be ensured by repeated aspirations, clamping the tube after irrigation during a forced expiration, or the use of one of the many valvular tubes which have been described. Dr. Churchill has not found these latter satisfactory owing to the difficulty in keeping the connexion between the tube and the chest wall air-tight for any length of time. Sealing the rubber dam to the chest produces maceration of the skin, which increases the risk of secondary infection in the cavity. He now adds to these measures the use of carbon dioxide. Henderson's inhaler is left at the patient's bedside and he is instructed in its use with such exercises as are suited to his individual needs. The average convalescent inhales the gas for five minutes 15 or 20 times a day. The dizziness and unpleasant subjective symptoms often experienced in respiratory gymnastics, largely due, in fact, to the blowing off of $CO_2$, do not occur when this gas is inhaled. Dr. Churchill has found that the stimulation of the gas throws all the respiratory muscles into action and restores or maintains the symmetry of the thorax, whereas exercises without the gas only bring the muscles of inspiration into action during the preliminary deep breath. A tracing shows how the forced expiration produces a positive intrapulmonary pressure and the forced inspiration a negative intrapleural pressure, and the much greater regularity of the effect of carbon dioxide over blow-bottles or coughing.

## THE MEASUREMENT OF X RAY DOSAGE

ON May 20th a joint meeting of the Rontgen Society and the Electro-therapeutic Section of the Royal Society of Medicine was held to hear the seventh Mackenzie Davidson memorial lecture delivered by Dr. A. Dauvillier, of Paris, who spoke on the Measurement of X Ray Dosage. The subject was fittingly chosen for an address commemorating a great radiologist, since it is one of great practical importance. At the present time many types of X ray dosimeters are in use. Most of them furnish an indication of the intensity of a beam of X rays, provided that the wave-length of these rays remains constant. In attempting, however, to compare the effects of X ray beams of different wave-length a difficulty arises with these indicators, for secondary radiations may be produced by X rays of one wave-length, but not by those of another, and most dosimeters therefore give no reliable estimate of the intensity of the respective beams. Hence the need for an international unit of X ray intensity and a standard method of measuring it has become acute and has led to the formation during the past year of an international committee to consider the problem.

In the course of his lecture Dr. Dauvillier discussed in some detail the mechanics of the action of X rays on matter. Early in the history of radiology, he said, Sir William Bragg had put forward the view that effects observed with X rays were due to the ionisation of matter irradiated by them, and time had amply verified this hypothesis. A considerable study had been made of the process of ionisation by X rays and a flood of light had been thrown upon it by the beautiful photographs of electron tracks obtained by Mr. C. T. R. Wilson. Recently measurements of the numbers of pairs of ions produced by electrons of definite speed had been made and the work done in ionising an atom had been determined. The data furnished by these fundamental investigations made it possible to gain an idea of the true absorption of X ray energy by matter and brought the absolute unit of radiation considerably nearer realisation. The concluding part of Dr. Dauvillier's lecture was devoted to the explanation of a method of measuring doses of X rays which he has evolved. He makes use of a small spherical ionisation chamber equally transparent in all directions to X rays and containing the heavy gas Xenon. When this chamber is exposed to the radiation the ionisation produced in the Xenon is about 500 times greater than is produced in the same volume of air and is sufficiently intense to be recorded on a micro-milliammeter. To render the indications of this instrument reliable for all wave-lengths it is calibrated against a large air-gap ionisation chamber. The use of a large chamber is necessary owing to the considerable distances travelled by the radio-electrons emitted when air is penetrated by X rays, and for correct measurement it is essential that these electrons should complete their tracks before reaching the walls of the chamber. With the help of this method Dr. Dauvillier has found that the energy per cubic centimetre required to produce an erythema of the skin is approximately 30,000 ergs.

## AN EXHIBITION OF MEDICAL ART.

AN exhibition of an unusual kind is to be seen at the Baltimore Art Museum. The exhibits are the work of the department of anatomical and medical art of the Johns Hopkins Medical School. The drawings of Max Broedel, founder and director of the department, are represented by some admirable illustrations of operative technique and dissection. Of especial excellence are the water-colour drawings of human and animal embryos, magnified usually 100 diameters, by William T. Didusch. There are also included in the exhibition coloured wax models by Vladimir Fortunato. One series illustrates in ample number the progress of the conservative operation of prostatectomy by the perineal route. It is unfortunate that the later members of the series are badly lighted. This criticism, however, does not apply to a model of nodular leprosy which is a masterpiece. It is evident that the exhibition represents an experiment, and that in the future similar work may be shown to even greater advantage. Thus the director of the department of embryology has added to the exhibits in his field careful and informative descriptions of the drawings. On the other hand, the series of guinea-pig paintings from the department of tuberculosis, showing the results of intracutaneous tuberculin under various conditions, are furnished with no clue to their meaning. A guide to their scientific interest would surely not detract from the artistic value of the drawings. It may be that in the future such exhibitions will be arranged so that lovers of art may become interested in the progress and versatility of scientific medicine.

Prof. A. J. Clark has been chosen to succeed the late Prof. A. R. Cushny in the chair of Materia Medica and Pharmacology in the University of Edinburgh.

Sir John Williams, Bart., G.C.V.O., consulting obstetric physician to University College Hospital and President of the University College of Wales, died on May 24th at the age of 85.

Dr. Ernest Septimus Reynolds, consulting physician to Manchester Royal Infirmary and Emeritus Professor of Clinical Medicine in the University of Manchester, died on May 22nd at the age of 65.

Dr. Hugh Cabot, C.M.G., professor of surgery and dean of the Medical Faculty of the University of Michigan, Ann Arbor, is coming over to take charge of Sir Holburt Waring's surgical clinic at St. Bartholomew's Hospital from Monday, May 31st, until Saturday, June 12th. During this time he will deliver four lectures in the Medical School—viz., Wednesday, June 2nd, at 12.45 P.M., Non-tuberculous Infections of the Kidney; Friday, June 4th, at 4.30 P.M., a second lecture on the same subject; Wednesday, June 9th, at 12.15 P.M., The Present Position of Prostatic Surgery; and Friday, June 11th, at 4.30 P.M., Tuberculous Disease of the Kidney.

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

## CLXXIV.

## THE TREATMENT OF PERIURETHRAL ABSCESS.

FROM a clinical standpoint periurethral abscess may be divided into two classes—those associated with the penile and those with the bulbous urethra.

### *Penile Periurethral Abscess.*

The first class of case is comparatively simple. The abscess arises in an infected follicle of Littré, as a complication of acute (rarely chronic) urethritis. A tender induration can be felt on the under surface of the penis. Left to nature the abscess frequently bursts externally, and a urinary fistula may result. Early incision per urethram is the best method of abruptly terminating these untoward possibilities. The operation is satisfactorily carried out under gas anæsthesia. The help of an aëro-urethroscope is desirable, but if the abscess is near the meatus, as it usually is, it may be dealt with by inserting a tenotome down the urethra.

### *Uncomplicated Bulbar Periurethral Abscess.*

By "uncomplicated" it is meant that there is neither acute retention nor extravasation present. In the majority of cases the abscess occurs behind a stricture of the bulbous urethra. This is a much more serious condition than the penile abscess considered above, for *bulbar periurethral abscess is the commonest cause of extravasation of urine.*[1]

Under general anæsthesia, with the patient in the lithotomy position, an incision is made in the perineum exactly in the middle line. There is frequently much induration around the walls of these abscesses, and one has to proceed to what appears to be some considerable depth before striking the pus, which, as often as not, is quite small in amount. The after-treatment consists in daily irrigation of the perineal wound with eusol through a Higginson's syringe, and the patient is encouraged to sit in a sitz bath for at least half an hour twice daily. When the inflammation has abated and the perineal wound looks quite clean—usually in about ten days time—the renal function is tested, and if this is found to be satisfactory the stricture of the urethra receives attention. Occasionally it is possible to dilate the stricture with bougies, but in my experience these cases usually require an internal urethrotomy. A catheter is then tied in. This allows rapid closing of the perineal wound. The catheter is changed every fourth day until the perineum is soundly healed. Throughout the after-treatment a mixture containing sodium acid phosphate gr. xxx. is given three times a day with urotropin gr. x. Before the patient is discharged he should be warned that the stricture requires regular dilatation. The end-results of the treatment of this condition are gratifying.

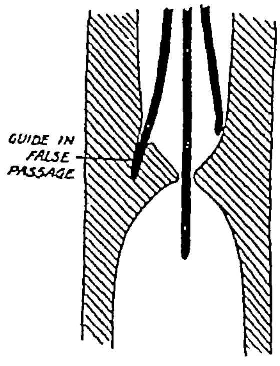
### *Periurethral Abscess with Extravasation.*

A periurethral abscess with extravasation represents a later stage of the condition described above. The general condition of the patient is usually grave. Oft-repeated rigors are the rule and may mislead the casual diagnostician. A local examination rarely fails to reveal the true nature of the condition. There is the obvious swelling in the perineum, the scrotum is infiltrated, and later the extravasation spreads up on the abdominal wall. The cellular tissues of the penis are involved about this time, and the condition rapidly passes on to gangrenous cellulitis. Sir Benjamin Brodie noted that a black patch on the glans penis was a harbinger of death. In all probability the patient has had more or less complete retention of urine for some days, and he is definitely uræmic. The grave general condition is due to combined septicæmia and uræmia. Nevertheless, it is astonishing what a large percentage of almost hopeless-looking cases will recover with prompt and careful treatment. On account of the uræmia a general anæsthetic is contra-indicated. I believe that the routine use of intrathecal stovaine has done much to reduce the mortality.

---

[1] Bailey and Huddy: Brit. Jour. Surg., 1924, xii., 153–161.

FIG. 1.



The "faggot" method of passing bougies.

The following procedure has given most satisfactory results. The urethra is washed out and an attempt is made to pass a bougie into the bladder. Great gentleness must be exercised, for the inflamed urethra is easily perforated. It is usual to be able to pass a No. 3 or 4 French bougie. In the absence of an instrument by which the bougie can be passed under direct vision the "faggot" method (Fig. 1) is of distinct value. This method consists in passing a second, third, and even a fourth bougie down the urethra alongside the first; by trying each in turn, one of the number is gently coaxed through the stricture. If the stricture is impassable Wheelhouse's operation must be performed. If the bougie has been passed (and this is possible in the majority of cases) it should be fixed in position. The patient is now put in the lithotomy position and a sandbag placed under the sacrum effectively exaggerates this position. Lane's tissue forceps are clipped upon the most dependent part of the infiltrated scrotum. These serve as scrotal retractors. By this method the scrotum is pulled up and the perineum clearly exposed to view. An incision now is made, strictly in the middle line, from the base of the scrotum to within half an inch of the anal verge. The incision is deepened until the abscess is opened. A finger is now passed into the wound and the bougie within the urethra is sought for by palpation. The floor of the urethra is next incised on to the bougie. The left index finger is passed into the dilated urethra with the pulp against the bougie. The finger is thus guided into the bladder. A large coudé catheter is then passed through the incision along the index finger into the bladder and secured to one side of the wound by a stitch.

*Drainage of the Cellular Tissues.*—The left forefinger is now passed through the perineal wound upwards and outwards, clearing the crus penis, and made to protude subcutaneously above and to the outer side of the symphysis pubis (see Fig. 2). The skin is then incised over the finger and drainage-tubes, with lateral perforations, are inserted as shown in the diagram.

*Incisions into the Infiltrated Tissues.*—In contrast with older methods fewer, but larger, incisions are recommended. There is a tendency on account of the infiltration for these incisions to be too superficial; they must penetrate the limiting fasciæ. If time permits hydrogen peroxide can be injected hither and thither into the infiltrated tissues by means of a Record syringe fitted with an aspirating needle, for it has been shown that the organisms in the exudate are mainly anaerobic.

*Dressings.*—Dressings soaked in eusol are applied over the abdominal wall, perineum, and scrotum. These are covered over by packing towels, and the whole is secured by a T-shaped bandage.

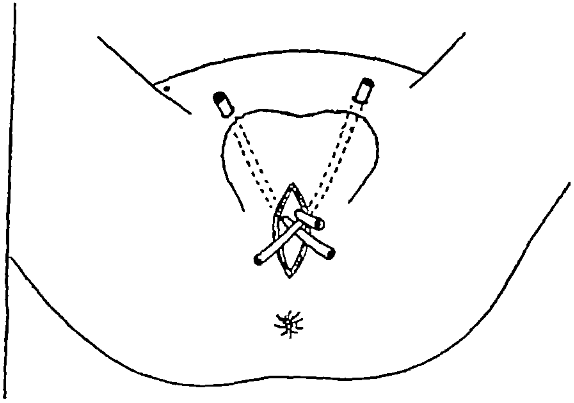
### *After-treatment.*

During the first 24 hours the patient is encouraged to drink as much fluid as possible. Rigors are usual during this period and are most satisfactorily combated by hot gin and quinine. The catheter is removed at the end of 48 hours. Every four hours all the wounds are irrigated with eusol, after hydrogen peroxide has been instilled for a few minutes. As soon as the general condition permits, sitz baths are instituted, and throughout the convalescence the sodium acid phosphate mixture is prescribed in liberal doses.

A *residual abscess* is frequently seen in the flank, just above the anterior superior iliac spine, and should be opened under gas anæsthesia.

When the infection has subsided, which is usually in about a month's time, the stricture should receive appropriate attention, as outlined above. Very great care must be taken to investigate the functional activity of the kidneys before undertaking the treatment of the stricture. A weekly blood-urea estimation during convalescence from the acute stage will indicate when the time is ripe for the second operation. The patient should not be discharged until the perineal wound is soundly healed. The long illness usually completely undermines the morale of these patients, and the weekly dilatation of the urethra becomes to them an ordeal of very considerable magnitude. The necessary dilatation calls for much tact and gentleness on the part of the surgeon. An instillation of 2 per cent. borocaine for five minutes before instrumentation goes a long way towards making the procedure painless.

FIG. 2.



Methods of drainage.

**HAMILTON BAILEY, F.R.C.S. Eng.,**
Surgeon, Dudley-road Hospital, Birmingham.

---

**LIVERPOOL: NEW MATERNITY HOSPITAL.**—The first part of the new maternity hospital is now ready for use and has been open to public inspection for three days. There has been a steady flow of visitors who acquired a link with the institution which it is hoped they will never forget. The first part, which is roughly one half of the intended whole, contains 54 beds arranged in prenatal, labour, and postnatal wards. The labour ward and operating theatre block forms one well-designed unit with anæsthetic, sterilising, and scrubbing-up rooms common to both parts. Lighting is admirable, one half of the large theatre being designed chiefly for use by day, and the other for times when artificial illumination is required. The wards are intended to accommodate only eight patients each and they have nurseries attached. A number of single-bedded rooms suitable for special cases is also provided. As an integral part of the hospital there is a large out-patient department with separate and well-equipped examination rooms, an antenatal clinic, and the central branch of the Maternity District Nurses' Home. The administrative offices, nurses' home, and resident medical officers' quarters are, of course, complete, and are modern and attractive. The whole of that portion of the hospital which is now complete is to be known as the Sir William Hartley Memorial Wing in acknowledgment of the generous bequest to which the new hospital largely owes its existence.

## ADVICE UPON DISINFECTANTS AND SICK-ROOM DISINFECTION.

BY HENRY R. KENWOOD, C.M.G., M.B. EDIN., L.R.C.P. LOND., D.P.H.,
CHADWICK PROFESSOR OF HYGIENE IN THE UNIVERSITY OF LONDON.

### *Some General Considerations.*

WHEN practicable, infection should be destroyed as near as possible to the fountain-head—the infectious human being. When the virus is contained only in the evacuations this is practicable; when it is given off from the nose and throat or skin it is impossible to achieve more than partial success, and the infection becomes disseminated throughout the room.

Although complete disinfection of an infected sick room is not possible until the sufferer is no longer a source of infection, there are obvious advantages, from the standpoint of the patient and nurse, in keeping down the infective elements in the room during the whole of the infectious period. With this object in view discharges from the mouth, nose, &c., may be collected by means of paper or rags and promptly put into the fire which is so desirable in every infectious sick room, before they can become dry, and much infection of the sick room may be collected and removed daily by damp sweeping and dusting.

In the destruction of infection we have not, in practice, to deal with naked organisms. They are always associated with more or less organic matter which itself may impede, reduce, or destroy the agent employed. Hence there must always be a time exposure to the disinfectant, and the agent employed must possess a permanence in action for at least 20 to 30 minutes. The handicapping effect of the medium in which the germ is embedded and the resisting power of different germs may vary considerably, and so knowledge and care are necessary in the selection of an agent which will meet all practical purposes.

Those disinfectants which by giving up oxygen soon expend themselves upon the dead organic matter are inferior to those which have a greater permanence of action and exert a selective effect upon the living organisms. Chlorine, potassium permanganate, and Condy's red fluid (a mixture of the permanganate and sulphate of soda) are oxidising agents, and chlorine loses strength under the ordinary conditions of use. The perchloride and the iodide of mercury, and the higher homologues of phenol, kill by their combination with the albumin of the organism and by their toxic effect, and they represent the most effective of the liquid disinfectants.

The strength at which a disinfectant is employed will depend upon two considerations: the resistance of the organism to be destroyed, and the amount and nature of the diluting material to which it is applied. Especially is it important to bear in mind the last-mentioned factor. Suppose, for instance, that a disinfectant is germicidal in 15 minutes when made up to a strength of 1 : 200; if this dilution is added to an equal quantity of urine the strength of the disinfectant will then be 1 in 400, and disinfection cannot be secured. Therefore agents added to liquid or solid matter must be made up to at least twice the strength employed for other purposes in order to ensure that after admixture they are not diluted to below their killing strength.

For every purpose it is best to employ either a liquid disinfectant or heat. Powders, gases, and vapours are less effective. Heat is a most valuable disinfecting agent. Infected articles that can be kept in boiling water for 20 minutes are thereby efficiently disinfected; but when this method is applied to bed and body linen stained with albuminous matter, such as blood or fæces, the stains should be removed by soaking in cold water and rubbing if necessary with a little soap, prior to placing them in the boiling water. Steam stoves are employed by local sanitary authorities for disinfecting mattresses, pillows, clothing, &c. This is found to be the most satisfactory way of securing the rapid penetration of heat sufficient for disinfecting purposes.

The mercury salts suffer from the drawback that they are very poisonous to human beings, and being colourless and non-odorous in solution may be mistaken for water; they attack and damage metal receptacles, and they precipitate albumin which may serve to shield micro-organisms. This precipitating effect can be greatly reduced, however, by acidulating the solution; ½ oz. of the perchloride, 1 oz. of hydrochloric acid, and 1 gr. of aniline blue to 3 gallons of water is a valuable disinfectant solution containing 1 : 1000 of the perchloride.

Phenol (carbolic acid) was formerly much employed for disinfecting purposes at a 5 per cent. strength, but it has been replaced largely by agents containing the higher homologues of phenol. They are mostly made up as emulsions. Two of the oldest of these agents are the well-known "Izal" and "Cyllin," which, like others now upon the market, are far less toxic, and being many times more powerful, are cheaper in use than carbolic acid; moreover, their odour in the sick room is, generally speaking, far more agreeable to the occupants.

### *Choice of a Liquid Disinfectant.*

Disinfectants containing higher homologues of phenol are to be preferred. This I say because they are the only agents which I know of which combine a high germicidal value with permanence of strength and low toxicity to human beings. Such agents should be put up in the form of a fine emulsion which remains stable under the conditions of use; for hard waters and urine accelerate de-emulsification in unstable emulsions, and an agent with its emulsion impaired may be almost, if not quite, valueless in practice.

The percentage of the higher boiling tar acids, the fineness of the emulsion, and its permanence when mixed with urine should therefore be the great determining factors in making a choice, and so great importance should be attached to physical tests designed to determine whether the emulsion "stands up" well in urine or sea-water, or tends to separate out, from any other cause, on keeping for a reasonable time, whether in bulk or after dilution. The stability of the emulsion may be determined by sight and by comparing the specific gravity of portions removed at different levels.

In addition to the above considerations, evidence should be required from workers of repute upon the relative powers of such agents against several pathogenic organisms (including those of typhoid and tubercle). If such tests have been applied to the germs in the presence of the organic matter with which they are commonly associated, I should not then expect a high germicidal power, but the agent with the highest efficiency under the test conditions should be selected.

The above considerations being favourable to more than one agent, my choice would fall upon the one which does not in any way injure the metal or other surfaces with which it may be brought in contact; is the least poisonous to the higher forms of animal life; and which possesses the maximum deodorising effect. I should also have regard to diffusibility and power of penetration, for especially is the wetting power when applied to dust an important factor when the agent is employed for spraying. This wetting power depends on surface tension, complicated, maybe, by surface concentration, preventing the running together of the liquid to form drops. A disinfecting agent in the form of a colloidal emulsion has, in dilute solution, a surface tension of half that of water, whereas the surface tension of, say, a solution

# MEDICINE AND THE LAW.

### *Professional Discipline—the Right of Appeal to the Courts.*

If a solicitor has been excluded from professional practice by order of the Law Society, he has a statutory right of appeal to the law courts. If a medical practitioner is removed from the Register he has no such right. Some critics have thought that this is an omission which should be remedied; it may, therefore, be worth while to notice how the right of appeal operates in the case of solicitors. The Law Society not long ago ordered a solicitor to be suspended from practice for six months. He had been out riding, and at 2.45 in the afternoon he called at a working men's club and asked for a glass of beer. He was told by the steward that he could not be served as the permitted hours had just expired. He then went up to the chairman of the club, who happened to be on the premises, and gave him a blow or a push, using unbecoming language. The occurrence was undoubtedly indecorous, but, when the solicitor was summoned for it at the police court, he received no heavier penalty than a fine of £2 and an order to pay £2 costs. The Law Society thereupon held an inquiry and suspended him as already stated and he appealed from the Society's order to the Divisional Court. His appeal was dismissed. The judges, even though the Solicitors Act gives a right of appeal, are evidently as unwilling to interfere with the jurisdiction of the Law Society as they have been reluctant to revise the decisions of the Medical Council. The Lord Chief Justice remarked that Parliament had deliberately made the Law Society master in its own house. The case was evidently one for the judgment and good sense of the Professional Committee, and there was not the slightest ground for thinking that they had misdirected themselves. The law courts, one may add, have always exercised a somewhat special jurisdiction over solicitors, for solicitors are officers of the Supreme Court; moreover, judges might well be thought to have expert knowledge of the standards which should be observed in the legal profession. Yet the Divisional Court refused to take the matter out of the hands of the Law Society and did not even call upon the latter to argue its side of the case.

Let us suppose for a moment that the case had concerned a doctor instead of a solicitor. The doctor, if similarly sentenced, would have had no right of appeal as a matter of course. He would have had no access to the law courts unless he could allege that the professional tribunal had been guilty of bias or that the proceedings had somehow been tainted with irregularity. But the solicitor's case which we have just described seems to indicate that an appeal to the law courts, where the right of appeal exists, is not likely to prosper unless there is some flagrant irregularity or misdirection. Any lawyer who has studied the cases decided by the General Medical Council in recent years would be slow to believe that, if a right of appeal to the law courts had existed under the Medical Act, the judges would have upset the tribunal's decision on any single occasion. The existence of a right of appeal to the courts may be reassuring, but those who advocate that such a right should be conceded must not expect too much of it. The judges would, no doubt, say of the General Medical Council—as they have said of the Law Society—that Parliament deliberately intended it to be master in its own house.

### *Workmen's Compensation—the "Odd Lot" Man.*

If a workman has been so seriously injured by an accident that his value in the labour market is gravely diminished, the employer can sometimes find him light duty within his capacity; if so, the workman can still earn wages and thus the maximum compensation need not be paid. But if, owing to bad trade, the employer cannot find the man an odd job of light duty, what is the position? This was the question answered by the Court of Appeal lately in Palmer *v.* Crawshay Brothers (Cyfarthfa) Ltd., a case reported in the *Times* on April 29th. A collier was seriously injured in 1915 in a shot-firing accident; he lost his left eye and his right eye was badly damaged. In 1923 he was given light duty as a watchman guarding coal stocks, but he was assaulted by thieves and was further incapacitated. After medical examination a year ago his compensation was reduced to 8*s.*, but on appeal to the county court it was raised to 10*s.* The judge said the man was so seriously incapacitated that nobody was likely to employ him except his former employers. He would have awarded the maximum compensation if the employers failed to find the workman suitable employment; he considered, however, that the applicant's right to recover compensation was, in view of the nature of his injuries, affected by labour conditions, there being much unemployment in the district. The Court of Appeal has now decided that the county court judge was wrong in taking the current labour conditions into account. The man was an "odd lot" case, and came within the dictum expressed by Lord Justice Moulton in Cardiff Corporation *v.* Hull in 1911. "Odd lot" men are workers who after an accident are left incapable of average capacity in any well-known branch of employment, men who are fit only for special uses and whose powers of work are not a merchantable article in some well-known line in the labour market. When a man is in that category, said Lord Justice Moulton, it is incumbent on the employers to show that he can, in fact, obtain the special employment which is all that he is fit for. The "odd lot" man, in fact, is totally incapacitated unless his employers can find work for him. Adopting this view, the Court of Appeal awarded the collier the full amount on the basis of total incapacity—i.e., 29*s.* 9*d.* per week.

### *Injury from Hair-Dye.*

Another purchaser of "Inecto" hair-dye has been awarded damages for injury attributable to its application. According to her counsel the dye caused sores on the head, a progressive rash, swelling, affection of the heart and nerves, and permanent disfiguration. It was admitted by the proprietors of "Inecto Rapid," who were the defendants, that their hair-dye had unfortunate effects for some customers, whose skin was by personal idiosyncrasy specially susceptible. It was argued, however, that the dye was accompanied by instructions, that the instructions said a test was necessary before using the dye, that the plaintiff, though she had read the instructions, chose to ignore the test, and that therefore she was negligent in applying the dye, had brought the whole trouble upon herself, and was alone responsible. The jury awarded her £500 plus a further sum agreed as special damage. Dr. B. M. Footner, consultant to the defendant company, used the phrase "Inecto dermatitis" which he claimed to have coined. It is, of course, the misfortune of the defendants in such a case that others are known to have suffered similar injuries and to have recovered damages on that account. Whether the hair-dye caused injury in a particular case and whether the vendors gave adequate warning of the danger (if danger there was) in the application of the dye, are pre-eminently questions of fact for a jury to decide.

# PARIS.

(From our own Correspondent.)

### *Protective Value of Anatoxin.*

Lereboullet, Boulanger-Pilet, and Gournay have tested the Ramon antidiphtheritic vaccine, anatoxin, in about 2000 children. Two injections given three weeks apart were effective in 95 per cent. of the cases and the addition of a third injection raised the success rate to 100 per cent. Anatoxin produces practically no local or general reactions, especially in children aged less than 8 years. It should be used particularly in children of 1 or 2 years old, because they are so susceptible to diphtheria, and as it seems to be in increasing demand by French families, the number of hospital cases of diphtheria is expected to diminish. Roubinovitch, Loiseau, and Lafaille have investigated the duration of immunity produced by anatoxin in children vaccinated in 1924 and re-examined 12 to 25 months later. Two injections proved necessary as a routine to assure immunity continuing for one to two years. A single injection, however, gave protection of this duration in about two-thirds of the cases. In a few cases three injections were required to immunise the patients for two years.

### *Hospitals and Sickness Insurance.*

The Chauveau Report, which has just been presented to the Aid and Hygiene Committee of the French Senate, deals with the relations between insured persons and the hospitals. It does not, however, solve the vital question which is exercising the minds of those responsible for the large public hospitals and of teachers of medicine and surgery. The legislation governing sickness insurance allows every insured person to choose his own physician, and the result is that many patients are sent to private sanatoriums or nursing homes. There is a danger that there will be such a falling-off in admissions to the great hospitals that medical teaching will become difficult. This tendency is especially obvious in Alsace. Prof. P. Merklen, writing in the *Presse Médicale*, says that the existing laws on sickness insurance will prove to be boomerangs and opposed to real humanitarianism. These laws are being combated by the national federation of French medical unions (syndicats), which are also uniting to protect physicians against the undermining of their positions, rights, and privileges by undue socialisation of any kind.

### *Legislation on Occupational Accidents.*

Occupational injuries are at present subject to a law of 1898 which permits injured employees to select their own physicians. This law, however, puts professional fees so low that physicians and pharmacists not infrequently ask employees for sums exceeding the officially stated allowances for which the employer is liable. Growth of this practice is tending to limit the employee's free choice of a physician, and it is therefore proposed that the existing regulations shall be modified by changing the official tariff.

### *Hospital Personnel and Professional Risks.*

The official French charities organisation, the Assistance Publique, is considering the question of providing pecuniary protection and indemnities for hospital interns exposed to infection and other professional risks. The only occupational classes not provided for by French legislation have been the medical, surgical, nursing, and other personnel of hospitals and the members of university faculties. The indemnities being discussed refer to allowances for partial or total disability and to pensions for widows and orphans. Disability percentages will probably range from 5 to 100 per cent. This new legislation is to operate as an addition to the present law of March 31st, 1919.

### *Students' Demonstrations at the Faculté de Médecine.*

On account of the fact that Prof. A. Prenant, who holds the chair of histology, gave evidence at the trial of Clerc and Bernardon, who were concerned in a communist murder of the rue Damrémont, certain student groups made such vigorous demonstrations during Prenant's courses that he was unable to go on lecturing. All courses and examinations in histology were officially suspended and this inflicted great hardship on many innocent students. The secretary of the Students' Association has taken up the matter and guarantees the obedience and courtesy of the students, so that the affair bids fair to end in harmonious resumption of lectures and examinations.

### *Inauguration of the American Hospital.*

The new and admirably equipped American hospital at Neuilly was formally opened on May 12th. At the ceremonies the American Ambassador presided, and addresses were given by the President of the French Republic, Marshal Foch, and others.

At the Paris Medico-legal Society, Desfarges recently reported a case of suicide by dial poisoning. Seventy-one tablets were taken, but the quantity of dial per tablet is not stated. The symptoms of intoxication were delayed because the tablets were swallowed without liquid of any sort, but treatment in hospital did not ameliorate the fatal coma. In France the sale of most hypnotics is unrestricted.

The Eleventh French Congress on Legal Medicine will be held from May 27th to 29th. Questions to be discussed include the diagnosis of drunkenness, determination of alcohol in the blood, physicians' depositions and oaths, testimony offered by psychopaths, traumatic arthritis, and the pathology of traumatism.

The Thirty-fifth Congress of the French Surgical Association will be held from Oct. 4th to 9th. The special subjects will be the pathology of the meniscus of the knee, conservative operations in inflammatory adnexal lesions, and the treatment of progressing gonococcal arthritis.

A vacation course on Diseases of the Liver and Pancreas, including Diabetes, will be held from June 28th to July 9th at the Clinique Médicale de l'Hôtel-Dieu. The course will be essentially practical and will be directed by Prof. Maurice Villaret. Particulars may be had from the secretary of the Faculté de Médecine.

---

## BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

### *Domiciliary Care of the Insane.*

AT a recent meeting of the Royal Medical Society Prof. Rudolf Fabinyi said that there was no greater need in the treatment of mental disease than for the proper nursing and supervision of insane persons outside hospitals and asylums. The majority of the insane, including psychopaths and imbeciles, could be kept within their own families, and this arrangement made nursing more pleasant, and permitted the patients to earn their living whenever they were able. Supervision in the home, he said, relieved the public purse by reducing the number of institutions needed; it safeguarded the public safety; and it was also of some prophylactic value, since care could be extended to those who had never been inmates of institutions, to those who had early symptoms only, and even to those who had merely a tendency to mental trouble. In some of these cases disease might be prevented by expert treatment. Such arrangements, he said, were already in operation in Germany, France, and North America. He had studied the two systems in vogue in Germany. An example of one of them was the Nürnberg-Fürth-Erlangen Fürsorge, established by Kolb, which had already been copied at Mannheim, Regensburg, and Munich. Under this scheme the Fursorgestelle was independent of the district lunatic asylum. At Frankfurt, on the other hand, the Fürsorgestelle, founded and directed by Raecke, was an organ of the municipal sanitary office, which (so it seemed) did not allow the experts so free a hand. The patients under care were not only those dismissed or on leave from institutions (with their own consent or that of their relatives), but also patients referred by the magistrates. These were mainly psychopaths. In Nürnberg-Fürth-Erlangen there were more than 1500, in Frankfurt nearly 3000, in Mannheim 420, and in Munich, where the Fürsorge had only been established last year, there were 300 patients under supervision. The Fürsorge did not confine itself to treating the psychic ailments of its patients but also settled their affairs for them, provided legal advice and advocates, procured work, and saw that they had medicine and small sums of money. In general, said Prof. Fabinyi, the scheme was a success, though it could not be denied that there were occasional accidents and suicides. Describing plans for a system shortly to be established in Budapest, he said that, like Kolb in Germany, he was in favour of slow gradual extension of the organisation. First of all the patients discharged from the huge asylum at Lipotmező were to be placed under care; next those voluntarily reporting would come under supervision. For the present the centre would be an office at the asylum, which would give free advice; later on this would be moved to the middle of the city; and, last of all, the organisation would undertake the care of cases referred by the magistrates.

### *Critical Position of Hungarian Doctors.*

The regrettable financial straits in which Hungarian medical men find themselves are described in an article recently published by Dr. Valko Rezsö. The proverb "Galen dat opes," he says, does not apply to Hungarian doctors, who have to fight a hard battle to gain even the bare necessities of life. This is not to be wondered at, for the number of practitioners in Budapest has been trebled in recent years. In 1919, before the partition, by which Hungary lost two-thirds of her territory and population, there were 5750 doctors in the whole country and 1814 in Budapest. According to the medical annual there were 2584 physicians in Budapest alone in 1925 and 5466 in the small territory left to Hungary. This unfortunate state of affairs, at a time of great economic difficulty, has made it utterly impossible for all these doctors to earn their living with the honesty on which the Hungarian medical profession has always prided itself. It is no exaggeration, in the words of Dr. Valko, to say that Hungarian physicians have to fight a life-and-death battle for their daily bread. In this struggle medical ethics are sacrificed and the consequence is that doctors do not even stop at criminal abortion. (The Minister of Labour has issued an Order relating to the notification of all abortion cases and enforcing the most stringent control of those midwives whose reputation is not above reproach.) Dr. Valko thinks that the serious financial difficulties of the doctors could best be solved on the following lines: Only the very best scholars should be admitted to the medical faculty of the university. Young doctors sent out from the university, clinics, and hospitals should be given the fullest support by local branches of the Medical Association. All vacant appointments should be registered and the register should be easily available for consultation. The Sickness Insurance should be reformed—this is already being done—so as to permit patients to choose their own doctors freely. Besides making these recommendations, he draws attention to the urgent need for improvement in the financial position of village and country doctors. Provision must be made for getting them suitable dwellings, for in most cases housing difficulties make it impossible for young doctors to settle in the villages. If a decent livelihood could be got in the countryside the capital would be relieved of many surplus doctors and there would no longer be three medical men to every 1000 of the population, as there are at present. Decentralisation is all-important. The problem of the old and invalid members of the profession could be solved, he suggests, by setting up some system of old-age pensions. If all these things were done it is possible that the next decade will bring back the old prosperity which the Hungarian profession enjoyed before the war.

### *Memorial to Prof. Moravcsik.*

A volume has been issued in memory of Prof. Rezsö Moravcsik by his late pupils. It contains a collection of dissertations dealing with the important problems of psychiatry and neurology and reflects the many-sided intellect and inspiring personality of this great teacher. It begins with a short account of his life by one of the most eminent of those whom he taught—Ödön Német. Then follow a series of the professor's own addresses and papers, and, lastly, a collection of 20 articles written by his pupils. The whole is published under his motto: "Officium ante omnia."

# Public Health Services.

## HEALTH OF THE CITY OF LONDON.

IN his survey report for 1925 Dr. W. J. Howarth discusses the problems peculiar to his district, which has a resident population of 13,000, a working-day population of some 400,000, and casual daily visitors who probably number as many again. The sites continually increase in value; every spare inch of land has to be utilised, and many of the residents are thus crowded into uncomfortable corners. Although the main streets are reasonably wide, many of the connecting lateral streets are very narrow—sometimes little more than alleyways. Scavenging is difficult as most of the premises are lock-up places, and there are only a few hours available for the collection of refuse if the work is to be completed by 9 A.M.; an important advance will have been made when the corporation has succeeded in enforcing the by-law that all refuse must be stored in impervious metal bins provided with lids. The feeding of the large day population is another big problem. A few business concerns cater for their employees on the premises, but the lack of room for extensions prevents this being done generally. The control of the catering tends to fall into the hands of large firms with up-to-date methods and well-organised kitchen establishments. The smaller unsuitable private restaurants are gradually disappearing. A lighter midday meal, "occupying not a quarter of the time of the former midday feast," is the rule, and the whole tendency of city life is to concentrate the work into fewer hours. The food-supply of the worker to-day, says Dr. Howarth, compares favourably with that of 20 years ago, and the chief fault lies with the customers themselves, who do not fully appreciate the essentials of a suitable meal. The increase in the newer type of cheap restaurants has certainly benefited large numbers of people by abolishing the haphazard meal of the penny bun and drink at the fountain.

The increase of business premises and the covering of site areas has made the City quite unsuitable as a general place of residence. Parents bring up children under considerable difficulties, for traffic renders the streets unsuitable for playgrounds until after 7 o'clock in the evening, and little children living on the fourth storey cannot get fresh air. Many buildings regarded as handsome and adequate structures in early Victorian days are now sublet in rooms; dominated by larger and higher buildings, they are now in dark corners. The wood-work of these older buildings is decaying and the fabric is past economical repair. These blots on the City will be materially reduced when the Hutchison-street and Vine-street areas have been dealt with. In the proposed reconstruction schemes accommodation will be provided both outside the City at Shepherdess-walk and inside the City in the Hutchison-street area. The Court of Common Council has approved the provision of 104 tenements at Shepherdess-walk, comprising 342 rooms. This will cost £95,000. The tenements are to include 6 five-roomed flats, 40 four-roomed flats, 36 three-roomed flats, and 22 two-roomed flats, each with its scullery, bathroom, and w.c. The tenements to be provided at Hutchison-street on the site of the demolished buildings will provide for about 250 persons. This provision will, of course, involve a charge on the rates. One of the difficulties in the City is to provide sanitary conveniences, another is to secure proper ventilation for underground kitchens, workshops, and restaurants. Several ingenious plans for dealing with this latter problem are included in Dr. Howarth's report. He is very anxious to secure a clear legal definition of the term "workplace," and is strongly of opinion that an office in which people are employed in clerical work only should be included under this term Control is especially necessary where basements are in continuous occupation. Dr Howarth hopes to see an annual improvement recorded in connexion with the sale, transport and handling of meat and meat products The meat regulations of 1924 are being gradually put into force, and prosecutions were successfully undertaken in October for failure by persons carrying meat to use overalls and head coverings The registration of places where food is prepared is an urgent requirement, and in addition prepared meat should be amongst the products in respect of which effective regulations preventing contamination are operative " It is anticipated that the slaughter-houses in Aldgate will shortly be closed so far as the slaughtering of cattle is concerned

The births registered in the City numbered 327, and of these 260 were to non resident parents The number of births credited to the City after the addition of 33 children born outside is 100, making a birth rate of 7 5 There were 705 deaths registered in the City during 1925, 633 being those of outsiders ' There were 81 of City residents in outside districts and the death rate is 11 7, the same as that for the whole metropolis There were six deaths of infants under 1 year making a rate of 60, and phthisis caused a rate of 0 07, as compared with 0 91 for the metropolis

The need for strengthening and enforcing the enactments against the pollution of the atmosphere by smoke is well illustrated by a table Another table shows that cremations in the United Kingdom numbered 2700 in 1925 as compared with 2300 in 1924 Full particulars of the meat dealt with in the markets are included in the report During 1925 courses of lectures on meat inspection were given by the medical officer of health, the veterinary surgeon and the senior meat inspector They were well attended by executive officers of local authorities in the home counties The Sanitary Committee has had under consideration the question of the damage and nuisance caused by the increasing number of pigeons in the City of London estimated to number about 4000 It might have been expected that the reduction in horse traffic with the lessening of nosebag droppings would have decreased the number of pigeons but this is probably compensated for by more people providing pigeon food bought from street vendors

### SPECIAL SCHOOLS.

*List of Certified Special Schools Recognised Institutions for the Training of the Blind and other Defective Students and Nursery Schools in England and Wales.* H M. Stationery Office. 1s.

THIS compilation will be found indispensable to school medical officers and useful to all who are concerned in the education of defective children and adults. The provision made appears ample at first sight but the impression fades when the accommodation reported as available is compared with the numbers of defectives known to the Ministry of Health and the Board of Education The list describes provision for about 45 000 defectives, whereas over 170,000 of such children are known to the school medical service, and many are admittedly not yet ascertained. The blind, deaf, and tuberculous child is well catered for but the needs of the epileptic and the partially blind and deaf—a recently recognised but important class—are still very poorly supplied Appropriate teaching is available for under 17 000 out of 30,000 known feeble-minded children The special schools are moreover, very irregularly distributed, London still has an undue proportion (174 out of 526) and many larger wealthy authorities do little or nothing for their afflicted children There is grave reason to fear that the provisions of the new Economy Act may be used to perpetuate, if not to aggravate this unfortunate state of affairs. Local vigilance will be necessary in the next few years to preserve for the physically and mentally handicapped that special training which is for them an essential preparation for the battle of life

### THE PORT OF TYNE.

In his annual report for 1925 to the Tyne Port Sanitary Authority Dr W E Harker states that 74 vessels were visited by him on account of reported or suspected sickness on board, two cases of scarlet fever, one each of small pox and enteric fever, were removed and necessary disinfection done No infectious disease was found among the 9110 alien passengers, who were mostly clean No case of cholera, plague or yellow fever came under notice, but 4538 rats were caught in 100 vessels, 83 were killed with sulphur dioxide in 15 ships, hydrocyanic acid was not used. The dead rats, more than half of which were black, were burnt in the ships furnaces. None was plague-infected Twenty-one ships from ports infected or suspected to be infected with cholera had their drinking water tanks emptied and purified The chief diseases reported during the previous voyage or found on arrival were: accidents 200 (10 deaths), venereal disease 78, feverish colds 81, malaria 35, influenza 19 (1 death), consumption 15 (2 deaths), pneumonia 11 (2 deaths) heart disease 10 (5 deaths) The main food imports into the Tyne were wheat, sugar, eggs, and fruit, of which were condemned 54 tons potatoes, 1206 lb corned beef, and 4 stone of oranges. The fish landed was good but 43 of 8058 fishing vessels had to be cleaned and deodorised In 9185 inspections of ships sanitary defects were found more often in foreign-going (11 per cent) than in coasting (3 per cent) ships Peaks forecastles, w c s, and bilges of 1108 vessels were found dirty and were cleansed, 1025 old beds were burnt on account of infection. Structural defects as follows were notified and rectified side ports for refit, 305, defective w c 's, 94, deck leaking, 80, defective stoves 58; water-tanks cleansed 21 The 18 water-boats of the port were examined and their tanks found in good condition The Tyne floating hospital is used for isolation and treatment of the more dangerous infectious diseases from abroad, and as a cleansing and disinfecting station; other infectious cases are sent to the city infectious hospital The usual measures were taken for the relief of venereal disease but Dr Harker offers no estimate of their usefulness

## SCHOOL MEDICAL SERVICE

IN the following table the figures given in the reports from Sheffield, Leamington Spa, and Taunton are summarised

| Name of town | No on roll | Av elem. school attendance | No of routine children examined. | No of special examinations and re-inspections | Percentage of children found on routine examination requiring treatment * |
|---|---|---|---|---|---|
| Sheffield | 81,271 | 72 772 | 26 221 | 115 308 | 15 46 |
| Leamington Spa | 3 323 | 2 935 | 1 095 | 1 937 | 9·6 |
| Taunton | 3,021 | 2 753 | 1 010 | 2 437 | 20·2 |

* Excluding uncleanliness and dental defects.

### *Sheffield*

Dr Thos Chetwood explains the unusual brevity of his report by the difficulty experienced in keeping pace with statutory requirements owing to illness in his staff, so that no time was available for other work Those familiar with his previous reports will regret the loss Financial restrictions continue to retard the natural growth of the work in Sheffield, although there is some evidence of progress. The extensions to the two open air schools have been in use this year, and the number of school places has been increased from 201 to 281 A new school for 150 mentally defective elder boys has received approval—another extension of high economic value for it is this type of school which makes employable and decent citizens out of those who would otherwise be burdens to the community The junior M D schools have accomplished much; out of 153 past pupils 96, or 63 per cent., are now employed, a proportion which is higher than that for the physically defective school (52 per cent.) or for the deaf (40 per cent.). The amount earned is small, but work with a wage of even 10*s.* a week is better than idleness. The physically defective schools include the King Edward VII. Hospital sanatorium school for surgical tuberculosis, staffed by teachers appointed by the Education Committee which is doing excellent work, and efficient after-care is given by the Cripples Aid Association. Orthopædic agencies in Sheffield fulfil the requirements of the Board, except that there is no orthopædic surgeon under the Education Committee—a serious omission. 289 children who had passed through an open-air school were followed up. Of these 162, or 56 per cent., returned to elementary schools, 70, or 24 per cent., left over age, while 28, or nearly 10 per cent., had to be referred to the tuberculosis officer. It is much to be regretted that the Redmire Camp scheme has been abandoned; a new country home for sick children was, however, opened last year by an organisation belonging to Sheffield teachers. The first case of small-pox during the recent outbreak was discovered at the school clinic.

### *Leamington Spa.*

Dr. W. L. Goldie, in his report on the Royal borough, depicts a locality which is fairly healthy and perhaps a little easy going. The percentage of defects found (9·6) is distinctly low, but the methods of dealing with exceptional children are not very extensive. Good work is done at the school clinic and the facilities for treatment in general appear to be adequate. Dental treatment, noted as necessary in 875 cases, was given in only 357 children. No children are noted as actually in need of treatment for malnutrition and no scheme exists for the provision of meals. There are no special schools in the borough and several feeble-minded and physically defective children are in attendance at elementary schools, apart from 38 who are merely delicate children. Special schools are necessarily less easy to provide in small communities, but a beginning might be made with an open-air school or class. Table 8, which gives a survey of the capacity and sanitary equipment of each of the eight schools, reveals considerable variation and apparent anomalies—for example, most of the schools have one class-room to 30 or 40 pupils, but one infant school seems to have only two class-rooms with 154 on the register. Dr. Goldie notes that none of the schools is provided with a drying room.

### *Taunton.*

Dr. J. Allen, who is also medical officer of health and in charge of the maternity and child welfare departments, gives a clear outline of the school duties which he has carried out unaided except for the part-time services of an ophthalmologist and of a dentist. Two nurses act as attendance officers in addition to their school work; a part-time dental nurse is also employed. During the year Dr. Allen has made a special inquiry into the number of feeble-minded, tuberculous, physically defective, and exceptional children in his area, and each child has been individually examined—no light task with the routine work as well to do. The proportions of blind and deaf children approximate closely to the figures estimated by the Board of Education, but he found 73 feeble-minded children against the Board's estimate of 24; 74 crippled children were noted compared to the Board's figure of 28; 90 delicate children were found where the estimated number would be 43, and 60 cases of active pulmonary or glandular tuberculosis as against 11. The disparity in the figures for mentally and physically defective children is not remarkable, as there is general agreement that the Board's estimates are on the low side, but the number of tuberculous children (confirmed by the tuberculosis officer) is disturbingly high. An orthopædic scheme is now in force jointly with the Somerset County Council, but the proposal for a new special school to be run on open-air lines has unfortunately been postponed.

## X RAY TREATMENT OF CANCER.

*To the Editor of* THE LANCET.

SIR,—The critical position of the X ray treatment of cancer at the present time is attributable to two main causes. First, the impossibility of arriving at accurate physical dosage, even with the newest and most complicated apparatus of the ionisation type, some of which, even in their commercial form, require the services of a whole-time physicist. The error of such measurements may reach 20 per cent., and the conception upon which current dosage tables are founded has been proved wrong by subsequent work. In particular Borrel, Altman, Glocker, Rothacker, and Schönleber have shown that these tables make too great an allowance for increase in depth dose by scattered radiation. Ionisation measurements have no advantage over the older pastille and photographic methods in the hands of an expert.

Secondly, the theories upon which X ray treatment has been based are now no longer tenable. The law of Arndt Schulz, which states that small doses excite, moderate doses inhibit, and large doses destroy, must be discarded in its entirety. It is this law which allowed the conception of an "irritation" dose to penetrate into Rontgen-therapy. Holzknecht has shown from clinical experience that the "irritation" dose does not exist independently, but is only an early stage of the destructive process which follows every Rontgen irradiation. When small doses are given the "irritation" stage can be observed for a longer time, when large doses are given the "irritation" phase is obscured by the destructive. Nather and Schinz, from large experimental material, have demonstrated the fallacy of the "irritation" dose.

The belief that every carcinoma can be destroyed by a dose of 90–110 per cent. of the skin dose (H.E.D) is no longer current. Failure was at first explained on the theory that some part of the growth must have received an "irritation" dose; then, when the refractory nature of certain tumours was obvious, the dose was considerably increased, with serious internal injuries as a sequel. We know now that the "irritation" dose does not exist. Further, instances of the successful cure of carcinomata by doses much in excess of the "carcinoma" dose prove that the specific "carcinoma" dose does not exist. Fischer says that carcinoma is a generic term for a class of tumours insufficiently classified, containing widely different types. These types differ in radio-sensitivity. Some will disappear after receiving 50–70 per cent. (H.E.D), others require 400–500 per cent. Martin, for epithelioma, gives 150–500 per cent., and Kummer gives 300–500 per cent. spread over ten days.

I have had the opportunity of observing the excellent results of treatment of epithelioma obtained by Rapp at the Samariterhaus, Heidelberg, using the "step-up" filter method. Introduced by Ghilarducci, the technique is essentially as follows:—

> The affected area is treated through a localiser, receiving on the first day 100 per cent. unfiltered, on the second day 100 per cent. filtered through 1 mm. aluminium, on the third day 100 per cent. through 2 mm. aluminium, on the fourth day 100 per cent. through 3 mm. aluminium, on the fifth day 100 per cent. through 0·5 mm. zinc. Allowing for modification to suit any given case the patient may receive a dose up to 500 per cent.

The results in epithelioma and lupus carcinoma are striking. Lupus carcinoma, incidentally, is common in Germany, a fact ascribed by Rapp to previous treatment of the lupus by X rays.

Granted then that the carcinoma dose does not exist and that different carcinomata possess a different degree of radio-sensitivity, the question now arises: Can the histological nature of a tumour serve as an index of its radio-sensitivity? Ulman thinks that squamous epitheliomata relapse after small or large doses of X rays, but that basal-cell carcinomata hardly ever relapse or give rise to metastases, however the dose may be varied. This view is opposed by S. and I. Forestier, who maintain that histological character does not influence radio-sensitivity to gamma radiation, basing their opinion on some cases of cancer of the cervix uteri.

*In former times the radio-sensitivity of cells* was believed to be a function of the degree of activity of cell metabolism and of the stage of differentiation—propositions inherent in the law of Bergonié and Tribandeau. We owe to Mohr, Holthusen, Lacassagne, Monod and Regaud the explanation that the effect of radiation upon a cell depends on a definite cytological stage; that in the testicle, for example, the vulnerability of the cell is at a maximum during cell division at the stage of equatorial arrangements of the chromatin meshes. This observation has been found to apply to normal cells and cancer cells alike, and Pordes has endeavoured to explain this upon *theoretical grounds*.

What practical inferences can we draw from these new points of view? First, that the law of Bergonié and Tribandeau is insolvent. Secondly, that the Wintz method is useless. This method, as is well known, consists in giving a total "carcinoma" dose during one séance, sometimes lasting 6–8 hours, with the idea of destroying all cancer cells at a stroke and giving them no chance of recovery. But fractional doses are now freely given without the least fear of provoking irritation, with the intention of influencing, at each irradiation, the cells which happen at that moment to be in the mitotic stage. Since the *exact time of this stage is unknown*, the irradiation times must be arbitrarily chosen. Forestier, in the hope of bringing some precision into this serious question, suggested his "index of karyokinetic activity," which represents the ratio of the number of cells in the division stage to those in the resting stage. The index so calculated determines the duration of application. Seth-Hirsch (New York) instead of using fractional doses keeps the tumour under continual weak action of X rays for eight days, calculating to reach the limit of tolerance only at the end of a week.

The old principles and views on which Rontgen-therapeutics *were formerly based are thus to be found* inadmissible and are being replaced by new theories, not yet assured of general acceptance, nor sufficiently well established for translation into terms of practice. The results of practice remain much the same; a complete cure cannot be promised, and radical surgical operation, whenever possible, remains the method of choice. To radiology there remains the field of prophylactic irradiation and of inoperable cases.

I have now outlined the causes which account for the deep pessimism which is general among Rontgen-therapists. Levy-Dorn jestingly states that radiotherapy can claim two successes—epilation and castration. Rapp thinks the method will probably be abandoned in favour of chemotherapeutics. What is the final destiny of radiotherapy it is impossible to foretell. The Russian poet, Poushkin, says: "A heavy hammer, breaking glass, forges a sword." Let us hope that the present period of transition will succeed in forging a sword which will deal the death-blow to one *of humanity's most cruel foes*—cancer.

I am, Sir, yours faithfully,

N. A. PODKAMINSKY, M.D.,

Administrator of the Rontgen Department of the All-Ukrainian Institute, Kharkow.

### *To the Editor of* THE LANCET.

SIR,—Duties in connexion with the national crisis prevented an earlier reply to the letter of Sir John Thomson-Walker in THE LANCET of May 1st. It is, of course, not to be expected that two parties looking at a problem from widely different angles should have similar views. Ever since I have been in a position to form any judgment it has been my view that in the treatment of any *disease* surgery must always be looked upon in the light of an expedient, pending the discovery of something better. It is not to the point that good results can be attained in certain cases of early malignant disease by operation. If the same result can be got by other means without removal of tissue, such means should be employed before any operation is attempted. The vast majority of patients dread operation, and if they can be cured without it *they will avoid a disturbance of physiological balance* which is an important factor in many cases. Radiology too is cheaper than surgery.

When Sir J. Thomson-Walker speaks of the hard rays in cancer having been for some time under careful trial in this country I should like to know where, when, and under what conditions the test was made. Whether surgery is at a "dead end," as I stated, is a matter of opinion, and I think I gave adequate reasons for mine. Regarding the "many serious risks" of hard rays to which he alludes, the fact is that his opinions are based on a different class of experience from my own. That there have been *disasters following on intensive X ray applications* I know probably as well as anyone—these are bound to happen while we are gaining experience in the use of any agent of equal power—and I have made it my business to investigate as far as possible every case that came to my notice. In some carelessness or incompetence or both were at work. Errors of judgment involving faulty technique, or the treatment of unsuitable cases, accounted for others, but I could find nothing reflecting on the system. If the technique is carefully carried out in early cases where the lesion is circumscribed and the general health not seriously impaired, then I am confident that radiology is without *the risks of operation and will achieve* as good or better results in a pleasanter way.

Sir J. Thomson-Walker takes exception to my having claimed "a high degree of success in the relatively few early cases of malignant disease that have been referred to me before there had been any surgical interference," and quotes the results in a few cases he was kind enough to send me. I was not thinking of these cases when I made that statement, and for the reason that I did not consider any one of them likely to be cured by any method at present known to us. If the prospect was so favourable why did not Sir J. Thomson-Walker deal with these cases himself? I can trace 15 *cases sent to me by him directly* or on his advice between August 14th, 1921, and Jan. 22nd, 1923. The ages vary from 55 to 81 with an average of over 62—a severe test for a method that depends for success on a reasonably normal vitality and recuperative power. Ten cases were malignant prostate, some with extensions to bladder, rectum, or glands. A few were complicated with an infection—a very fatal combination in my experience. It will be five years in August since the first, and three years last January since the last of these cases came into my hands. Does Sir J. Thomson-Walker wish to infer that a larger number of these cases would have been alive now if *(a)* they had been left alone, or *(b)* he had dealt with them himself by the usual surgical methods?

The fact is that the cases quoted differ in no degree from the usual type passed on to radiologists by surgeons with the further disadvantage of the age being unduly high. It would be difficult to find a more unsuitable series of cases on which to test the value of *any method of treatment, and it* is not open to anyone to say that the claims on behalf of the Erlangen system are extravagant until a proper test, under the conditions existing at its place of origin, has been made and found wanting. No such test has yet been made in this country.

I am, Sir, yours faithfully,

London, May 21st, 1926. REGINALD MORTON.

## EMETINE IN THE TREATMENT OF HEPATIC ABSCESS.

### *To the Editor of* THE LANCET.

SIR,—May I answer, very shortly, Colonel Thurston's letter in your issue of *April 10th, which I have*, unfortunately, only just seen. 1. My patient had declined operative interference. 2. He recovered. 3. Colonel Thurston relies on aspiration and emetine —in that order—but, in my opinion, he over-estimates the effect of aspiration and under-values that of emetine. I am, Sir, yours faithfully,

May 19th, 1926. V. S. HODSON.

## BACTERIAL INFECTION AND ACCIDENTAL HÆMORRHAGE.

*To the Editor of* THE LANCET.

SIR,—I wonder whether the "close relationship" found by Prof. F. J. Browne to exist between accidental hæmorrhage and toxic states[1] is really due to the "associated increased head of urea in the blood," or to the concomitant rise of general blood pressure. Accidental hæmorrhage, in its worst forms, seems to differ little from cerebral hæmorrhage in its worst form. On the post-mortem table the pregnant uterus, the seat of (concealed) accidental hæmorrhage, apparently differs but little from the brain in cases of extensive cerebral hæmorrhage (which is nearly always concealed). If a pregnant woman with slightly damaged kidneys eats unwisely at night, and in consequence twists and turns in bed, unable to sleep, the placental sinuses may give way, just as in the non-pregnant, with damaged cerebral arteries, a rupture under similar circumstances may occur. In the former case the placental sinuses give way unless they are sufficiently "supported"; their conservation depends on the intra-amniotic pressure. If this is maintained high, as in primigravidæ, accidental hæmorrhage is less likely; if it is on the average low, as in pregnant multiparæ, accidental hæmorrhage is more likely. 80 per cent. of the cases of eclampsia occur in primigravidæ; 80 per cent. of the cases of accidental hæmorrhage in pregnant multiparæ. It is a curious and interesting distribution.

Eclampsia and accidental hæmorrhage, it is stated, are both forms of the "toxæmia of pregnancy." THE LANCET, not so very long ago,[2] stated that in the former type there is no accumulation of nitrogenous waste products in the blood; to-day we read that in the latter type there is "an increased head of urea in the blood." But obstetric authorities (in the recent past) have suggested that the different forms of the various toxæmias of pregnancy depend in the presence or not, and in sufficient quantities, of respective antibodies. Eclampsia occurs because one type of antibody is not produced in sufficient quantity and accidental hæmorrhage because a different type of antibody is insufficient. These authorities must have missed the highly significant increase of the urea, &c., in the blood in the latter cases reported to-day in THE LANCET.

It is, however, curious that if a woman be the subject of chronic nephritis and become pregnant, that the pregnancy should advance near or quite to term; and that even the babe in some—indeed, in many—cases of accidental hæmorrhage, should be so well developed as appears. Prof. Whitridge Williams, in London, in April, 1925, reported a case of this type. From the photograph shown on the screen (of the uterus and babe in situ), the child appeared a normal full-time infant, well developed. The patient developed anuria from which she died. And in an annotation last week[3] you refer to the effect on the body (in the non-pregnant state) of diminishing the amount of kidney substance beyond a certain extent. If between 62 to 68 per cent. of the kidneys be removed, "the animal survives for a considerable time" . . . "the deciding factor between death and survival being whether the remaining portion of the kidney hypertrophies" or not. If the kidney is so essential to the individual, how in pregnancy can a well-developed babe be produced if the mother be the seat of chronic nephritis? How, then, can chronic nephritis be the cause of accidental hæmorrhage?

I submit we have got to look elsewhere. A "black" (pregnant) uterus may look like a "black" brain, but it also simulates a "black" eye, and may even have the same sort of pathology.

I am, Sir, yours faithfully,
R. H. PARAMORE, F.R.C.S. Eng.

Rugby, May 22nd, 1926.

## THE COUNCIL OF INDUSTRIAL MEDICINE.

*To the Editor of* THE LANCET.

SIR,—Of recent years there has been a steady increase in the number of large industrial concerns in this country employing medical men and women to advise their management regarding factory hygiene, the prevention of avoidable accidents, illness, and industrial diseases, and to assist in promoting the general well-being of the staff and workpeople. This increase, and the example set in America for some years past, led to the formation last year of "The Council of Industrial Medicine" as an association of British industrial physicians and surgeons. This Council already has over 40 members and meets regularly on the fourth Friday in each month at 12, Stratford-place, London, when discussions take place on the various problems confronting this comparatively new branch of preventive medicine. The Council is also the British section of the International Congress on Industrial Accidents and Diseases which held its fourth meeting in Amsterdam last autumn. It is hoped that the International Congress of Industrial Accidents and Diseases will at some future date hold a meeting in London. The actual date will be fixed by the International Committee.

The Council of Industrial Medicine is anxious to coöperate with all British medical practitioners (at home and abroad) who are specially engaged in industrial medicine. The executive are well aware that there are still a number of medical practitioners in Great Britain giving general or special medical services to industrial concerns with whom so far it has not succeeded in getting in touch, and will be grateful if any such will write to the Secretary, Council of Industrial Medicine, Federation of Medical and Allied Services, 12, Stratford-place, London, W. 1.

I am, Sir, yours faithfully,
D. A. COLES,
Chairman.

May 25th, 1926.

## IS LEUKÆMIA CANCEROUS?

*To the Editor of* THE LANCET.

SIR,—May I call your attention to certain facts which are a source of difficulty to humble followers of modern cancer research work. First, Ellerman and others have published many papers concerned with the transmission of leukæmia in the fowl. It can be transmitted by a cell-free filtrate. There seems to be no doubt now that it is typical leukæmia although it was formerly argued by some that it might be an obscure form of tuberculosis. Secondly, Rous, Gye and Barnard, and others have worked with another transmissible tumour which is a spindle-celled sarcoma and which has apparently no affinity with leukæmia. Thirdly, quite a number of others have worked with frankly non-transmissible tumours which everyone would admit to be cancerous.

In all three cases the work is sufficiently easy to follow because enough information is given about the original growth to permit of some idea of its nature. But there is another class of case in which doubts do arise. This class has long been known under a great variety of names—chloroma, lymphosarcoma, sarcomatosis, &c. Cases present apparent tumour formation in association with the generalised tissue and blood changes of leukæmia. I have not detailed references by me, but I have no doubt that many people would call such cases cancer and would base cancer statistics on them. Hastings Gilford seems to envisage the added tumour formation as being of the nature of a malignant change in the previously non-malignant leukæmia.

Now, although leukæmia may in one direction come very close to cancers, in the other it merges into a series of clinical pictures which seem to have little or nothing to do with cancer. And in all cases, including the lymphosarcoma or sarcomatosis type, it is sharply divided from cancer *by being at its inception a generalised disease.* Cancer is at its inception strictly localised. There is a further hint of some fundamental difference in nature in the fact that a sarcoma of bone, for instance, will expand and thin out the bone over it which a leukæmia marrow will never do, and in the fact that sarcoma impairs the function of an organ to the extent of its involvement of that organ, whereas a whole organ—e.g., a kidney—may be pervaded with leukæmic growth and yet suffer no perceptible impairment of function.

Other differences might be cited, and even if experts may not consider them conclusive there is no question but that they raise doubts which ought to be settled. If any part of modern cancer research is being based on what is in fact leukæmia, conclusions arrived at are ipso facto suspect until the above-mentioned disparities are explained and harmonised. No one seems to have thought it worth while to attempt such explanation and précis writers often fail to mention what sort of growth is being dealt with. It follows that readers are involved in difficulties and are inclined to doubt the propriety of endowing cancer research without any definite decision as to what constitutes cancer.

I am, Sir, yours faithfully,
GORDON WARD.
Sevenoaks, Kent, May 16th, 1926.

# Obituary.

## JOHN HEDLEY CROCKER, M.D., D.S.Sc.Vict.

ON May 17th Dr. J. H. Crocker died suddenly at Brighton, where he had been living for some years in retirement. He was 67 years of age. Born of a West Country family he was brought up in Tavistock and came to London to study medicine at Charing Cross Hospital, where he distinguished himself as a student and held house appointments. After voyages to China and Japan as ship's surgeon, he went to Eccles to take charge of a Friendly Societies' Medical Association, but soon afterwards took up private practice in the town and made a name for himself as a very able practitioner who took a great deal of trouble over his cases. Dr. Crocker had qualified as M.R.C.S. Eng. in 1884. In 1892 he graduated with first-class honours in the Victoria University and two years later, whilst in private practice, took the M.D. at Victoria University and also the diploma in Sanitary Science. This was followed by his appointment to the public health service. In general practice, his tact and charm of manner and his remarkable gift for winning the confidence of his patients had been immense assets, and also his aptitude for conveying to patients in non-technical language an accurate idea of their condition. These qualities of mind and character stood him in equally good stead when, partly for health reasons, he turned to administrative work. He became successively medical officer of health for Eccles, and for the new Manchester Port after the opening of the Ship Canal, and finally went to Richmond, Surrey, where, in spite of a serious operation and poor health, he carried on his work with keen interest. Even when he retired to Brighton he did not lose touch with everyday affairs, and he seemed to have several years of useful and well-earned retirement before him; as a member of the East Sussex County Council his advice and knowledge of public health were in constant demand. In each of the communities which he served during his life Dr. Crocker won a high reputation, and many colleagues will remember him as a good friend, always ready to do a good turn to others, and with a capacity for enlivening the occasion. He leaves a widow and one child.

## HENRY BROUGHAM GUPPY, M.B., C.M. EDIN., F.R.S.

THE death of Dr. H. B. Guppy at Martinique on April 23rd, at the age of 72, brings to an end a long career of scientific observation and investigation. The son of the late Dr. T. S. Guppy, of Falmouth, he was educated at King's School, Sherborne, and at Queen's College, Birmingham, proceeding to St. Bartholomew's Hospital, and the University of Edinburgh for his medical training. Graduating in 1876, he entered the Naval Medical Service, and was sent out to the Far East; it was as surgeon of a surveying schooner in the Western Pacific that he laid the foundations of his scientific work. Whilst engaged in oceanography he made use of his opportunities to study the formation of coral reefs in the Solomon Islands, and on leaving the Navy in 1885 devoted his attention to this branch of natural history. In 1887 he investigated coral reef formation in the Keeling Islands and Western Java, and his interest was attracted at this time towards the problems of plant dispersal, which mainly occupied his later years. On this and similar subjects he made many shrewd notes and deductions, and in recognition of his work on the geographical distribution of animals and plants, he received the gold medal of the Linnean Society in 1917 and was elected F.R.S. in the following year. Dr. Guppy was a man of an intensely inquiring turn of mind, and a good illustration of his ability to do valuable work wherever he happened to be is found in a contribution[1] to the *Proceedings* of the Royal Physical Society of Edinburgh, in which he describes a mass of observations on changes of temperature in the small and large rivers and ponds in the immediate neighbourhood of Kingston-on-Thames, and indicates their importance to the flowering and propagation of plants. As an author he will be chiefly remembered for three books: "Observations of a Naturalist in the Pacific" (1906), "Studies in Seeds and Fruits" (1912), and "Plants, Seeds, and Animals in the West Indies and Azores" (1917). Each of these contains a wealth of information invaluable to the student of plant geography, and it is in the last of them that Dr. Guppy develops his differentiation theory, according to which the restricted biologic groups represent derivatives of cosmopolitan types differentiated in correspondence with the integration of environment, and especially climatic environment. Several other books also reflect his wide interests and thoughtful mind.

Dr. Guppy was twice married, but leaves no children. He lived at Fowey in Cornwall.

## THE LATE MR. HUGH BRAUND KENT.

MR. H. B. Kent, who died at Tongshan on Nov. 24th last, was a man of considerable ability, and, although only 43 years of age, had distinguished himself in North China as a surgeon. We are indebted to Dr. John Fawcett for the following particulars of his career and work.

Hugh Braund Kent was the fourth son of Mr. Horace Kent, barrister-at-law, of Cholsey Mill, near Wallingford, Berkshire, and was educated at Oxford High School. Entering Guy's Hospital in 1904, he became popular amongst his contemporaries and proved his merit as a student. In 1908 he graduated in medicine in the University of London and was appointed clinical assistant at Guy's in the following year. Circumstances, however, compelled him to enter some kind of practice and to forego the house appointments which would have followed. In 1909 he left hospital and accepted a post in the Colonial Service in West Africa; in the following year he went to Tongshan as principal medical officer of the Kailan Mining Administration and the Chinese Peking-Mukden Railway.

When Kent took over this work in July, 1910, there was a hospital for foreign residents and for the

---

[1] Vol. xii., 1894.

Chinese at Tongshan, but it was by no means fully equipped for the practice of modern medicine and surgery. By the time of his death last year the hospital had undergone a great change; it had been greatly extended and thoroughly fitted out for work of almost every kind. To effect such an improvement the coöperation and support of his employers were, of course, essential, but it was Kent's initiative, perseverance, and recognised ability which ensured that they were freely given. In his relations with the Chinese he was remarkably successful, and he so won their confidence as even to overcome their prejudices against surgical operation. The money required for the hospital's X ray apparatus was subscribed mostly in small sums by the Chinese themselves.

Fifteen years is a short time in which to establish a reputation as a first-class surgeon, and yet Kent did it in spite of grave disability at times from ill-health. For the last 13 years of his life he suffered recurrences of illness bad enough to render many men permanent invalids; but his ill-health seemed only to brace him to renewed activity. In 1919 he obtained leave to come home and work for the degree of M.S. Lond. and again in 1923 for the diploma of F.R.C.S. Eng. In both of these examinations he was successful.

"The value of a man's life," writes Dr. Fawcett in an appreciative note, "is measured not in length of days, but in what he accomplishes in the short space allotted to him. and in that sense Kent kept the measure filled to the brim. Nevertheless, his friends here and in China cannot cease to deplore the fact that he died so young and withal so full of promise for the future; happily he ripened early and lived long enough to reap some of his sowing, although the full harvest was never garnered. . . . He had the true surgical instinct, the keen eye and sure hand, and the confidence based on knowledge; he possessed the mind and will to overcome difficulties, the inability to recognise defeat. In fact, he was the very type of Englishman eminently fitted for the pioneer work he undertook in a foreign country—work which redounded not only to his own credit, and incidentally to that of his parent medical school of which he was so fond, but at the same time was of incalculable benefit to his fellow creatures in that great and far continent of China to which he devoted the best years of his short life."

### JAMES MACDONALD, M.D. EDIN.

Dr. J. Macdonald, who died on May 10th at Carlisle in his 70th year, had a large practice in the city. He was born in Edinburgh and educated at the Edinburgh Royal High School and at the University, where he took his M.A. degree before he was 18 years of age. In 1881 he graduated in medicine and worked as assistant to doctors in Newcastle and Manchester before going to Carlisle in 1884. Some two years afterwards he entered practice on his own account, and his services were in such demand that his work soon became very heavy. In 1895, however, he found time to write a thesis on diphtheria which gained him the M.D. degree and was commended. For about 40 years, moreover, he was medical officer to the Carlisle Fever Hospital and he held a number of other public appointments in the neighbourhood, including that of medical officer to the Carlisle Rural District Council. Before the Insurance Acts came into force he also served the Sick Society carried on by the workers at Messrs. Carr's factory, and since 1917 he had been chairman of the Cumberland Panel Committee. He was also deeply interested in the work of the British Medical Association. Many kinds of sport found in him an active supporter, and one who had knowledge as well as enthusiasm; he played Rugby football for his school and university. Dr. Macdonald was twice married and leaves a widow and two sons, one of whom is likely to carry on his father's practice. Another son was killed during the war.

# The Services.

## ROYAL NAVAL MEDICAL SERVICE.

Surg. Capt. R. F. Clark is placed on the Retd. List with the rank of Surg. Rear Adml.

Surg. Lt.-Comdr. H. B. Padwick to be Surg. Comdr.

Surg. Comdr. A. R. Davidson is placed on Retd. List with rank of Surg. Capt.

J. M. Sloane to be Surg. Lt.

Lt. W. H. Mobley is placed on Retd. List.

### ROYAL NAVAL VOLUNTEER RESERVE.

Prob. Surg.-Lt. R. W. H. Tincker to be Surg. Lt.

## ROYAL ARMY MEDICAL CORPS.

Maj. J. W. C. Stubbs is restd. to the estabt.

Capts. R. A. Flood, C. C. Jones, J. Rowe, and H. C. D. Rankin to be Majs.

The undermentioned are restd. to the estabt.: Maj. R. G. Meredith, half-pay list, late R.A.M.C.; Capt. C. Armstrong, half-pay list, late R.A.M.C.

Temp. Lt. A. L. Moorby relinquishes his commn.

### ROYAL ARMY RESERVE OF OFFICERS.

Lt.-Col. R. A. Cunningham, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

### MILITIA.

Capts. H. C. G. Pedler, E. S. Rowbotham, and J. Melvin to be Majs.

### TERRITORIAL ARMY.

Capts. A. M. Johnson and C. A. Webster to be Majs.

Capt. H. L. Barker (I.M.S., retd.) to be Capt.

M. L. Sutcliffe to be Lt.

The King has conferred the Territorial Decoration upon the undermentioned officers: Lt.-Cols. A. W. Moore and P. H. Mitchiner; Majs. W. F. Denning, H. E. S. Richards, and A. L. S. Tuke; and Capts. (Maj. Prov.) H. Pinto-Leite and A. C. M. Savege.

## ROYAL AIR FORCE.

The undermentioned are granted short service commissions as Flying Officers for three years on the Active List: R. J. I. Bell, R. G. Freeman, and D. Oliver (who is seconded for employment at the Hull Royal Infirmary).

Flight Lt. M. Coghlan relinquishes his temporary commission on ceasing to be employed.

Flight Lt. D. McLaren is promoted to the rank of Squadron Leader.

## INDIAN MEDICAL SERVICE.

Majs. J. Taylor, A. D. Stewart, R. A. Chambers, R. H. Bott, J. Morison, S. G. S. Haughton, A. S. Leslie, J. F. James, A. P. G. Lorimer, H. B. Scott, G. McG. Millar, H. H. Thorburn, F. H. Salisbury, and C. R. O'Brien to be Lt.-Cols.

The King has approved the retention of the temp. rank of Capt., on perm. appt. to the I.M.S., as Lt. by E. T. N. Taylor.

The King has approved the retirement of Lt.-Col. G. E. Stewart.

Col. A. N. Fleming, A.D.M.S., Sind-Rajpatana District, has been appointed Honorary Surgeon to the King, in succession to Col. P. Dee, retd.

Maj. J. S. S. Martin, Indian Station Hospital, Multan, officiates as Deputy Assistant Director of Medical Services at Army Headquarters, vice Maj. G. R. Lynn, on leave. Maj. A. F. C. Martyn to be Specialist in Dermatology, Rawalpindi district, vice Maj. W. B. Rennie, vacated. Capt. C. G. G. Keane to be Specialist in Otology, Eastern Command, vice Capt. C. H. C. Byrne. Capt. G. A. Hildreth to be officer in charge, Brigade Laboratory, Bynnu, vice Lieut. K. M. Bharucha.

## DEATHS IN THE SERVICES.

Lieut.-Colonel Lewis Allen Irving, O.B.E., A.M.S., retd., who died on May 15th, aged 76, at 22, Westgate-terrace, S.W., was the youngest son of the late Major-General Alexander Irving, R.A. Educated at Dublin and in Germany he entered the Service as assistant surgeon in 1871, becoming lieut.-colonel after 20 years' service, and retiring in 1896. He saw service in South Africa and India, and was commandant of the Military Lunatic Hospital, Netley. Later he became a medical officer for recruiting in the London district, and on the outbreak of war was engaged in the relief of Belgian refugees. For his services he received the O.B.E. in 1918, and the Belgian Order of Leopold. After the war he interested himself in the Chelsea branch of the Incorporated Soldiers' and Sailors' Help Society and the Emergency Help Fund of the British Red Cross Society.

Ex-Service Men in Asylums.—The annual report of the British Legion for 1925 states that there are still more than 6200 ex-officers and men in mental institutions, and a further 390 in the Border-line Hospital at Ewell.

The late Dr. R. W. Wilson.—Dr. Reginald William Wilson, who died on May 6th, was for 37 years medical superintendent of the Croydon Union Infirmary. He received his medical education at St. Mary's Hospital, qualifying as M.R.C.S. Eng. in 1882 and L.R.C.P. Edin. in 1884. At 28 years of age he was appointed the first medical superintendent by the Croydon Guardians. He leaves a widow and two sons.

Rates on Hospitals.—The important Royal Infirmary at Cardiff and its branches have hitherto been assessed to local rates on a nominal basis. The assessment committee have just lowered the assessment still farther, the total of £434 being reduced to £170.

North-Western Tuberculosis Society.—Sir Robert Jones will read a paper at the Medical School, the University, Manchester, at 3 p.m. on Friday, June 4th, entitled Some Notes on the Treatment of Tubercular Joints. All medical practitioners who are interested are cordially invited.

Queen Charlotte's Maternity Hospital.—Arrangements have been made at Queen Charlotte's Hospital, Marylebone-road, London, for the accommodation of an increased number of medical students and practitioners, who can now be received at short notice for courses in practical midwifery.

The late Dr. W. Stamford.—Dr. William Stamford, who died on May 6th at the age of 84, was a Cambridgeshire man by birth. He studied at the Middlesex Hospital and qualified as M.R.C.S., L.R.C.P. in 1871. Nearly 60 years ago he settled in Tunbridge Wells and for 30 years was medical officer of health. In 1911 he resigned this post but continued in private practice, temporarily resuming his public work during the absence of his successor on military service in 1916. In 1912 he was elected to the town council which he served loyally until two years ago, when he had to give up the work owing to ill-health. For three years his health had been failing. Both in a public and private capacity he did good work for his town, and his interest in medical matters was shown by contributions to medical journals. He leaves a widow.

Salford Coroner Adopts New Procedure.—Mr. A. Howard Flint, the deputy Salford coroner, opened an inquest on May 14th on a woman who died on May 11th. A young woman in custody was charged on suspicion of having caused the death. Mr. Flint adjourned the case after taking evidence of identification and the doctor's statement. He said that this was an entirely new procedure in Salford, and explained that in a Bill before Parliament dealing with the holding of inquests there was a provision enabling coroners, where a person was in custody charged with murder, manslaughter, or infanticide, to postpone an inquest pending the result of criminal proceedings. Such a course, he said, obviated the duplication of evidence, and saved witnesses unnecessary inconvenience. It was also fair to an accused person, who would not be prejudiced by anything that occurred in a coroner's court. Although the measure had not yet become law, he proposed to take the responsibility of adjourning the case until after the hearing before the magistrates.

Sir William Osler Memorial Volume.—This memorial publication has just been issued under the auspices of the International Association of Medical Museums. It is an attractive volume containing 630 pages of memorial articles and bibliographic annotations with over 100 fine illustrations. Forewords have been written by Prof. William H. Welch and by the late Sir Clifford Allbutt, and the volume contains a large series of reminiscences and appreciations written by over 100 colleagues, friends, and pupils. Following this biographical and memorial section is a classified and annotated bibliography of Sir William Osler's publications, the work of several collaborators, which reveals Osler's many-sided activities and constitutes a source of reference alike to the research worker and medical historian. The book is completed by a full bibliography of writings about Osler. The volume has been privately published and is now available at the subscription price per copy of $10, or £2. Cheques should be made payable to the International Association of Medical Museums (Osler Memorial Number), and may be forwarded to Dr. Maude E. Abbott, Managing Editor, Osler Memorial Number, McGill University, Montreal, Canada, or to Sir Humphry Rolleston, Southfield, Trumpington-road, Cambridge.

Hull Royal Infirmary Extension.—Mr. Philip Reckitt has given the East Mount Estate of 50 acres as the site for the proposed annexe to this hospital.

The late Dr. W. Bryce.—On May 13th Dr. William Bryce, of Glasgow, died suddenly whilst walking in the street. He was 60 years old and had been in practice in the east end of Glasgow for nearly 30 years. In 1889 he graduated in medicine at the University of Glasgow and proceeded to the M.D. degree two years later. He was medical officer to the Glasgow Parish Council and had held a Territorial commission as lieut.-colonel in the R.A.M.C.

Lebanon Hospital for Mental Diseases.—The twenty-seventh annual meeting of the Lebanon Hospital, which is established at Asfuriyeh, Beyrout, Syria, will be held at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W., on Tuesday, June 1st, at 4.30 p.m. (Tea at 4 p.m.) Dr. E. W. G. Masterman will preside, and all who are interested will be welcome. Particulars of the work of the Lebanon Hospital may be had from the general secretary, Miss Hilda Fox, at 67, High-street, Marylebone, London, W. 1.

Royal Sussex County Hospital.—This hospital is now more than 100 years old, and at a meeting of the governors on May 18th it was decided to adopt a scheme for bringing it up to date, which will involve the expenditure of £25,000. The existing nurses' home is to be extended; new quarters are to be provided for the domestic staff, and the present operating theatres, which were put up 25 years ago, are to be enlarged. About 1500 major operations are now done during the year. Structural alterations are to be made which will increase the number of beds by 50 or 60. At present accommodation is altogether deficient; there is a waiting list of 130, and too few beds are available against emergency. A county meeting will probably be held and an appeal launched. At the governors' meeting the President, Lord Leconfield, paid a tribute to the work of volunteers who helped the hospital to carry on during the strike.

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS.

### *Whitsuntide Ajournment.*

The House of Commons adjourned for the Whitsuntide recess on Thursday, May 20th. They will reassemble on Tuesday, June 1st.

## HOUSE OF COMMONS.

### Tuesday, May 11th.

### *War Pensions Administration.*

The House went into Committee of Supply on the Civil Service Estimates, Mr. James Hope, chairman of committees, in the chair.

On a vote to complete the sum of £63,501,900 for salaries and expenses of the Ministry of Pensions for the current year 1926–27,

Major Tryon (Minister of Pensions) said that the vote before the Committee would bring the total expenditure on war pensions up to the end of the present financial year to £725,176,986. This was the largest expenditure on war pensions made by any of the countries engaged in the Great War. The cost of administration was £1,962,900, which showed a reduction of £404,700 on last year. Ninety-seven per cent. of the money voted was spent in direct benefit to the pensioners. The number of men medically examined had fallen off greatly. In the six months ended Dec. 31st, 1922, 279,701 men were examined by medical boards; in the same six months of 1925 the number had fallen to 63,000. The staff employed in the daily work of the Ministry had declined in numbers more rapidly than the total expenditure. In 1922 the Ministry were employing 92,000 persons; on March 31st of the present year the staff had fallen to 11,358, including 3000 staff employed in the hospitals of the Ministry. Of the total male staff 97 per cent. were ex-Service men, and nearly 60 per cent. were men who had been in some degree disabled by war service. Referring to the effects of the general strike, Major Tryon said that the facilities for reaching hospitals and clinics or attending for medical examination had, of course, been affected, but he had made arrangements for providing transport where it was essential, and he was glad to say that the food supplies to the Ministry hospitals had worked satisfactorily. Changes in local administration, which had been in process for two or three years, were now being brought to completion. These changes included the closing of the regional offices and the disappearance of the advisory councils associated with them. It was his intention to make the War Pensions Committees and the Central Advisory Committee at the headquarters of the Ministry as effective as possible in coöperation with the official administration.

He and Lieut.-Colonel Stanley, the Parliamentary Secretary to the Ministry, had visited the area offices in more than one-third of the country and had discussed with the chairman of the War Pensions Committee and the responsible medical officers and the chief area officers and their assistants the practical working of many branches of local administration. They found that generally everything was working smoothly and satisfactorily. Steps were being taken to meet practical difficulties where they occurred. The expenditure on medical services was estimated for the current year at £3,141,000, a decline of £317,000 on the previous year. The decline was due (1) to the fact that fewer men were asking for, or were being required to undergo, medical examination for pension purposes, and (2) to the medical and surgical treatment required by disabled officers and men steadily and quite naturally becoming less. The number of in-patients maintained on the charge of the Ministry was 15,000. During the past year 10 institutions belonging to the Ministry, or at their disposal, were closed, leaving 53 hospitals in working order at the present date The largest item in the Ministry's expenditure—the cost of pensions and cash benefits of all kinds—accounted for £58,772,900 for the current year. This was a decrease of £3,177,000 on the previous year. At present, out of the whole body of a million adult beneficiaries of the Ministry, there were 750,000 disabled officers and men, widows, and adult dependents who were in receipt of final awards or other forms of life pension, and for whom practical stability of tenure as pensioners had been secured. Less than 200,000 officers and men were in receipt of conditional pensions.

Progress was reported.

### THURSDAY, MAY 20TH.

### *Education of Semi-mentally Deficient Children.*

Colonel DAY asked the President of the Board of Education what arrangements now existed for the education of semi-mentally deficient children in England and Wales.—The DUCHESS OF ATHOLL replied: My right hon. friend assumes that the hon. Member is referring to the children who are educationally retarded but are not certifiable as mentally defective. Provision is made by an increasing number of local education authorities for the education of such dull and backward children in special classes on the general lines indicated in paragraph 14 of Circular 1341.

### *Sanitary Condition of Offices.*

Lord HENRY CAVENDISH-BENTINCK asked the Minister of Health whether the attention of local authorities had been directed by his department to the judgment in the case of Bennett v. Harding (1900), as to their power to inspect offices and insist on their sanitary condition; and, if not, whether he would consider the desirability of doing so—Mr NEVILLE CHAMBERLAIN replied: Yes, Sir, the attention of local authorities was drawn to this judgment in a Home Office memorandum of 1912. The judgment does not expressly refer to offices, and it may be well to have a test case to make the position clear

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 15TH, 1926

# Medical Diary.

## SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, May 31st.—5.30 P.M., ODONTOLOGY, Clinical Meeting, followed by the Annual General Meeting: Election of Officers and Council. At this meeting it is proposed to make a presentation to Sir Frank Colyer in recognition of his devoted services as Hon. Curator of the Museum for the past 25 years.

TUESDAY, June 1st.—5.30 P.M., MEDICINE. Annual General Meeting. Dr. P. J. Cammidge: Pituitary Glycosuria. Dr. O. Leyton: Hypoglycæmia.

WEDNESDAY.—5 30 P.M., GENERAL MEETING OF FELLOWS. Sir Jagadis Bose: The Action of Alkaloids and Cobra Venom on the Pulse of the Plant and Animal. 8.30 P.M., SURGERY. Dr. W. E. Gye. The Origin of Tumours. Mr. J. E. Barnard will give a demonstration on microscopical methods.

THURSDAY.—Summer Meeting. 3 P.M., LARYNGOLOGY. Sir William Willcox: Nasal Sinusitis as a Cause of Toxæmia. (Members are requested to send cases bearing on the paper not later than 2.30 P.M.) Dr. A. Logan Turner and Dr. F. E. Reynolds: A Fatal Case of Leptomeningitis following Operation on the Ethmoidal Air Cells: with Microscopical Demonstration of the Path of Infection. Epidiascopic Demonstration: Dr. W Jobson Horne: The Rôle of the Lymphatics in Laryngeal Disease, and the Rôle of the Larynx in Lymphatic Disease.

FRIDAY.—Ordinary Clinical Meeting at 10.30 A.M. (Cases at 9.30 A.M.), LARYNGOLOGY. Cases and Specimens will be shown by Mr. Lawson Whale, Dr. D. R. Paterson, Mr. Bell Tawse, Mr. Douglas Guthrie, and others. 3 P.M., OTOLOGY: Summer Meeting Prof. W. E. Dixon: The Permeability of the Choroid Plexus to Certain Constituents of the Cerebro-Spinal Fluid. Dr A. A. Gray: A Hitherto Undescribed Structure in the Bird's Labyrinth.

SATURDAY.—OTOLOGY: Summer Meeting (continued). 10 30 A.M. (Cases at 9.45 A.M.) Dr. W. H. Hartridge: The Fundamental Experiments on which the Resonance Theory is Based. Cases will be shown by Mr A. H. Cheatle, Mr. W. M. Mollison, Mr. Alex. Tweedie, Mr. M. Vlasto.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, May 31st, to SATURDAY, June 5th.—Special afternoon demonstration in clinical surgery on Monday, at the Royal Northern Hospital, by Mr. F. D. Saner at 2.30 P.M.—Special demonstration in clinical ophthalmology on Thursday, by Mr. Hepburn at the Royal London Ophthalmic Hospital at 12.45 P.M. These demonstrations are open to all members of the medical profession without fee.—CHILDREN'S CLINIC, [illegible] street, Marylebone road, N.W. Special course [illegible] diseases of children at various Hospitals and [illegible] consisting of demonstrations and lectures [illegible] and afternoon sessions as per programme.—[illegible] HOSPITAL, Denmark Hill, S.E. Further [illegible] from the Secretary of the Fellowship of [illegible]

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, May 31st.—10 A.M., Surgical [illegible] W. E. Tanner. 10 30 A.M., Gynæcological [illegible] Mr. A. E. Giles. Throat, Nose and Ear [illegible] Mr W. Ibbotson. 2 P.M., Medical, [illegible] and Gynæcological Clinics Operations [illegible] Demonstration of Cases in the [illegible] H. W. Carson. 6.30 P.M., [illegible]

TUESDAY, June 1st —2 P.M., Medical, [illegible] and Ear Clinics, Operations. [illegible] The Diagnosis and Treatment [illegible]

NATIONAL HOSPITAL, Queen-square, Bloomsbury, W.C.

TUESDAY, June 1st.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Mr. Armour: The Surgery of Compression Paraplegia.

THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Hinds Howell: Disseminated Sclerosis.

FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Dr. Collier: Aphasia.

MANCHESTER AND SALFORD HOSPITAL FOR SKIN DISEASES, Quay-street.

THURSDAY, June 3rd.—4.30 P.M., Dr. Marianne Peach: Lupus Erythematosus.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

FRIDAY, June 4th.—3.30 P.M. (at the Royal Hospital), Dr. G. Simpson: Treatment of Fractures.

## Appointments.

CADDY A., M.D. Lond., F.R.C.S. Eng., has been appointed Ophthalmic Surgeon to the Royal National Orthopædic Hospital, Great Portland-street.

Certifying Surgeons under the Factory and Workshop Acts: BUTTAR, F. L., M.B., Ch.B. Edin. (Salisbury); BAISS, L. A., M.R.C.S., L.R.C.P. Lond. (Swanage); MACKENZIE, J. M., M.B., Ch.M. Aberd. (Newport, E. Riding); KERR, A. E., M.B., Ch.B. Cantab. (Petworth).

## Vacancies.

*For further information refer to the advertisement columns.*

*Acton Hospital.*—Res. M.O. £150.

*Birkenhead Education Committee.*—Asst. M.O. £600.

*Bolton Union, Townleys Hospital.*—Med. Supt. £900. Second Asst. M.O. £225.

*Bournemouth Convalescent Home.*—Asst. Med. Supt. £200.

*Brighton, Royal Sussex County Hospital.*—H.P. £150.

*Bristol, Cossham Memorial Hospital, Kingswood.*—Res. M.O. £150.

*Bristol Eye Hospital.*—Hon. Consulting P.

*Bristol General Hospital.*—Hon. Clin. Assts.

*Cambridge, Addenbrooke's Hospital.*—H.S. and H.P. Each at rate of £130.

*Cambridge University, Pathological Laboratory.*—John Lucas Walker Studentship. £300.

*Cardiff Royal Infirmary.*—H.S. for Ear, Nose and Throat Dept. £50.

*Central London Throat, Nose and Ear Hospital, Gray's Inn-road, W.C.*—Res. H.S. £75

*Charing Cross Hospital.*—Asst. Phys. to Skin Dept.

*Chelsea Hospital for Women, Arthur-street, S.W.*—Jun. H.S. At rate of £100. Also Sen. H.S. At rate of £120.

*Cheshire, Joint Sanatorium, Market Drayton, Salop.*—H.P. £250.

*City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E.*—H.P. At rate of £100.

*Coventry and Warwickshire Hospital, Coventry.*—Fourth H.S. £125.

*Cumberland County Council.*—Asst. County M.O.H. £600.

*Derbyshire Education Committee.*—Two Asst. School M.O.'s. Each £600.

*Derbyshire Royal Infirmary, Derby.*—Venereal Dis. O. £750.

*Dreadnought Hospital, Greenwich.*—Phys.

*Durham County Council, Education Department.*—Asst. School M.O. £600.

*Elizabeth Garrett Anderson Hospital, 144, Euston-road, N.W.*—Asst. P.

*General Lying-in Hospital, York-road, Lambeth, S.E.*—Res. M.O. At rate of £100.

*Glasgow, Lightburn Joint Hospital, Shettleston.*—Res. M.O. £350.

*Great Yarmouth General Hospital.*—H.S. £150.

*Hampstead, General and North-West London Hospital, Haverstock-Hill, N.W.*—Pathologist. £600.

*Hospital for Sick Children, Great Ormond-street, W.C.*—H.P. and H.S. Each at rate of £50.

*Hull Tuberculosis Sanatorium, Cottingham, E. Yorks.*—Res. M.O. £504 13*s.* 10*d.*

*Huntingdon Administrative County.*—Asst. County M.O. and Asst. Sch. M.O. £600.

*Leicester Royal Infirmary.*—H.S. At rate of £125.

*London Hospital, E.*—Hon. Asst. Anæsthetist. Also Hon. Anæsthetist.

*London Temperance Hospital, Hampstead-road, N.W.*—Res. M.O. At rate of £175.

*Manchester, Hospital for Consumption, &c.*—Hon. Asst. P.

*Mauritius Government Mental Hospital, Beau Bassin.*—Asst. Med. Supt. 7500 rupees.

*Metropolitan Hospital, Kingsland-road, E.*—Hon. Anæst. Also Ophth. S.

*Miller General Hospital for South-East London, Greenwich-road, S.E.*—Res. Cas. O. £150. H.S. £125.

*Oxford, Radcliffe Infirmary and County Hospital.*—H.S., Obstetric H.P. Each at rate of £120.

*Queen Mary's Hospital for the East End, E.*—H.P., two H.S.'s, Obstet. H.S., and one H.P., and Cas. O.

*Queen's Hospital for Children, Hackney-road, Bethnal Green, E.*—Cas. O. At rate of £100.

*Royal Northern Hospital, Holloway, N.*—Ophth. S.

*St. John's Hospital, Lewisham.*—Asst. S. in Ear, Nose and Throat Dept.

*Sheffield Royal Hospital.*—Sen. Cas. O. £150.

*South London Hospital for Women, South Side, Clapham Common, S.W.*—Asst. P.

*Stoke-on-Trent City.*—Asst. M.O. £500.

*Sudan Medical Service.*—Four M.O.'s. £E.720.

*Swansea Hospital.*—H.S. for Ophth. and Aural Depts. £200.

*Victoria Hospital for Children, Tite-street, Chelsea, S.W.*—Sen. Res. M.O. £250.

*West London Hospital, Hammersmith, W.*—H.P., H.S., Aural H.S., and Res. Cas. O. Each at rate of £100.

*Westminster Hospital, Broad Sanctuary, S.W.*—Asst. H.P. &c. At rate of £52.

*Winchester, Royal Hampshire County Hospital.*—H.S. At rate of £150.

*Windsor, King Edward VII. Hospital.*—Res. M.O. and Jun. H.S. At rate of £200 and £100 respectively.

The Secretary of State for the Home Department announces a vacancy for a Medical Referee under the Workmen's Compensation Act, for the Districts of the Doncaster and East Retford County Courts (Circuit No. 18). Applications from Surgeons should reach the Private Secretary, Home Office, London, S.W., not later than June 14th.

## Births, Marriages, and Deaths.

### BIRTHS.

ANDERSON.—On May 15th, at Rosemount, Bearsted, Kent, the wife of J. C. Anderson, M.D., of a daughter.

BANKS.—On May 16th, at Ty-Mawr, Aberdare, the wife of Harry Banks, F.R.C.S., of a daughter.

BLACKLEY.—On May 12th, at Ashton-on-Ribble, Lancashire, the wife of F. J. Blackley, M.D., of a daughter.

CLAPHAM.—On May 21st, at Madeley House, Park-road, Peterborough, the wife of Harold Clapham, M.R.C.S., L.R.C.P., of a daughter.

HEPPLE.—On May 20th, at Chelsea, the wife of Captain R. A. Hepple, M.C., R.A.M.C., of a son (prematurely).

RAISON.—On May 13th, at Prior's Croft, Sir Harry's-road, Edgbaston, Birmingham, the wife of Cyril A. Raison, F.R.C.S., of a son.

SEVERN.—On April 20th, at Hong-Kong, the wife of Dr. A. G. Millott Severn, of a son.

SHAW.—On May 10th, at Christ Church-road, S.W., the wife of Dr. J. G. Shaw, of a son.

STEWART.—On May 10th, at Dial House, Bourton-on-the-Water, Glos., the wife of Dr. R. B. Stewart, of a daughter.

### DEATHS.

AMSDEN.—On May 24th, at Lancaster-gate, Walter Amsden, M.R.C.S., F.R.G.S., aged 60.

CROCKER.—On May 17th, very suddenly, John Hedley Crocker, M.D., B.Ch., D.P.H., of "Kingswood," Surrenden-road, Brighton, late Medical Officer of Health for Richmond, Surrey.

DUTCH.—On April 30th, 1926, after a long illness, Major Henry Dutch, M.D., T.D., aged 64 years, at his residence, 8, Berkeley-street, W. 1, beloved husband of Minna N. Dutch and deeply loved father of Councillor Miss Hilda Dutch.

FRASER.—At Woodlands, Elderslie (the residence of his son-in-law), on the 19th inst., in his 86th year, Donald Fraser, M.D., F.R.F.P.S., late of Paisley and latterly of Connel Ha' Cothal, Aberdeenshire.

HARVEY.—On May 4th, at Hamilton, Bermuda, Eldon Harvey, O.B.E., V.D., M.R.C.S. Eng., L.R.C.P. Edin., in his 74th year.

HOWARD.—On May 19th, at the Mowle, Ludham, Norfolk, Arthur Dashwood Howard, M.D.

KEMPSON.—On May 10th, suddenly, Frederick Claude Kempson, M.B. Cantab., Vicar of St. Newlyn East, Cornwall, aged 58 years.

KENYON.—On May 20th, at St. Margaret's-terrace, John Edward Kenyon, M.R.C.S., L.R.C.P., aged 79.

PACKARD.—On May 21st, at Kedleston, the Rev. Henry Charles Packard, M.D., Rector of Kedleston, Derby, in his 70th year.

SHAW.—On May 3rd, at "The Leazes," Goodmayes, John Custance Shaw, Medical Superintendent, West Ham Mental Hospital, aged 59.

THOMPSON.—On May 18th, at Beaumont-street, Oxford, after a few hours' illness, Harold Thompson, M.R.C.S., L.S.A., aged 73.

*N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

LEICESTER ROYAL INFIRMARY.—The annual report contains some interesting comments upon the influence of trade depression on workmen's contributions which, in this instance, show a slight falling off after years of consistent growth. Had it not been for the diversity of manufacturing interests in the city the financial uncertainty of the year would have been much greater. About 60 per cent. of the adult in-patients are members of approved societies which have granted support in relation to about 40 per cent. of their members treated in the hospital, and it is pointed out that if all approved societies with surpluses adopted hospital benefits the total contributions would yield some £7000 towards the £30,000 which the institution spends on the treatment of insured persons. A preponderating percentage of out-patients are members of approved societies which, however, make no return except by small annual contributions in a few instances.

# Notes, Comments, and Abstracts.

## THE DANGEROUS DRUGS ACTS.

### THEIR APPLICATION BY THE PHYSICIAN AND THE PHARMACIST.*

BY SIR WILLIAM WILLCOX, K.C.I.E., C.B., C.M.G., M.D., F.R.C.P. LOND.,

PHYSICIAN TO ST. MARY'S HOSPITAL, LONDON.

ADDICTION to the "dangerous drugs" to which the special Acts relate is rare in Great Britain. I made this statement in the Norman Kerr memorial lecture in 1923, and the same conclusion was reached by the Departmental Committee on Morphine and Heroin Addiction, which issued its report in January of this year.

It is often asked: Why should all these troublesome laws and regulations be made to deal with a condition which is uncommon in the country? The answer is that "the Dangerous Drugs Acts" are the outcome of a profound international public opinion which for many years has been steadily growing.

#### *Movement to Restrict the Use of Dangerous Drugs.*

As long ago as 1788 Warren Hastings declared opium to be "a pernicious article of luxury which ought not to be permitted but for the purpose of foreign commerce only." and in 1817 the directors of the East India Company wrote that "if it were possible to prevent the use of the drug altogether, except strictly for the purpose of medicine, we would gladly do it in compassion to mankind."

In 1871 the British Society for the Suppression of the Opium Trade was formed with Lord Shaftesbury as its first president, and in 1893 a Royal Commission was appointed to consider the opium problem in India. Although, however, the gravity of opium addiction was fully realised by this Commission no active measures of importance resulted from its work.

The United States became directly concerned in the Far Eastern opium problem when the Philippine Islands were ceded to them by Spain in 1898, and the International Opium Commission of Shanghai in 1909 was largely the result of President Roosevelt's initiative. This was the first great step in dealing with the problem from an international standpoint. An attempt to carry the work a step further was made at the International Opium Convention at The Hague in December, 1911, and January, 1912, and a general course of action was agreed upon, to which the 14 countries coöperating gave sanction. It was not, however, to become effective until the other countries not participating had agreed, and a satisfactory result was delayed by the outbreak of the war.

The peace treaty of Versailles contained clauses leading to the ratification of the Opium Convention. Under the terms of the Convention the consenting nations agreed to frame Acts dealing with dangerous drugs, and in this country the Dangerous Drugs Act was passed in September, 1920, by which (section 7) power was given to make regulations to control the manufacture, sale, possession, and distribution of the drugs in question. Minor regulations and amendments were made, and in May, 1923, the Dangerous Drugs and Poisons Amendment Act was passed. In March of the same year a memorandum on the duties of doctors and dentists under the Act of 1920 was issued by the Home Office.

In July, 1916, under the Defence of the Realm Act, orders were made dealing with the sale of opium and cocaine which were similar in character to those of the Dangerous Drugs regulations of 1921, and in May, 1916, an Army Council Order under the same Act prohibited the sale of certain narcotic drugs to any member of H.M. Forces except in the dispensing of medical, dental, or veterinary prescription. This schedule of narcotic drugs included barbitone, codeine, Indian hemp, benzamine (i.e., eucaine), chloral hydrate, sulphonal, and their preparations and derivatives.

These war emergency regulations dealing with dangerous drugs and narcotics worked smoothly and satisfactorily, and their success paved the way to the issuing of the dangerous drugs regulations of 1921.

#### *Recent Developments in Great Britain.*

It will be interesting to note the further developments in relation to the Dangerous Drugs Acts, though these have not yet resulted in actual statutory regulations.

In April, 1923, a Departmental Committee, with Dr. Smith Whitaker as chairman, was appointed by the Minister of Health to investigate the value for therapeutic purposes of possible substitutes for cocaine and the risk of such substitutes becoming drugs of addiction. This committee has not yet issued its report, but very valuable original work has been done at Cambridge, which has resulted in the discovery of the borocaines. These are valuable substitutes for cocaine; they are much less toxic and it is believed that they will not give rise to addiction.

In September, 1924, a Departmental Committee, with Sir Humphry Rolleston as chairman, was appointed by the Minister of Health to inquire into morphine and heroin addiction, and specially to consider the circumstances under which these drugs may be supplied to persons suffering from addiction and the precautions necessary to avoid abuse. This committee issued its report on Jan. 21st, 1926. Its work has been of great value, since it has enabled the views of specially experienced members of the medical and pharmaceutical professions to be heard in detail and impartially considered and reported upon.

Not the least valuable part of the report is the definition of addict as "A person who, not requiring the continued use of a drug for the relief of the symptoms of organic disease, has acquired as a result of repeated administration an overpowering desire for its continuance, and in whom withdrawal of the drug leads to definite symptoms of mental or physical distress or disorder."

The committee pointed out the types of cases of addiction in which administration of morphine or heroin may be regarded as legitimate medical treatment. This relieves the physician and pharmacist of any possible suggestion of lack of care. *Consultations in certain cases* were recommended, and it was suggested that infringement of the regulations by medical men should be dealt with by a specially constituted medical tribunal as an alternative to a conviction in the courts. It was also recommended that in suitable cases the Home Secretary should have power to withdraw a practitioner's authorisation to prescribe dangerous drugs as well as to possess and supply them, and it was recommended that doctors who do not dispense should be required to keep a simple record of their purchases of dangerous drugs. The system of notification of addicts which exists in certain countries was given full consideration, and it was not considered desirable to recommend such a system for this country.

On Feb. 11th, 1925, at the first Opium Conference of the League of Nations, special recommendations were made which made the importation, sale, and distribution of opium a monopoly of the Government. On the 19th, at the second Opium Conference of the League of Nations, special recommendations were made whereby *all* preparations containing heroin of whatever strength and galenical preparations (tincture and extract) of Indian hemp should come under the operation of the Dangerous Drugs Act and Regulations. *The above recommendations have not yet been legalised* in this country.

#### *What are the Dangerous Drugs?*

As at present scheduled they are morphine, cocaine, ecgonine, heroin, and medicinal opium with their salts or preparations. Additions to these have been suggested.

*Codeine.*—Is this a dangerous drug? or, in other words, is its use likely to lead to addiction? In my opinion codeine should not be regarded as a dangerous drug. It is a drug which is taken almost always by the mouth, and is not administered hypodermically. In the course of an extensive toxicological experience I have never yet met with a case of codeine addiction. I have, during the past 25 years, frequently prescribed codeine, usually in combination with other analgesic drugs such as aspirin, phenacetin, or pyramidon for the relief of pain, and have never observed any signs of the development of addiction. The addition of codeine to the list would greatly restrict the use of a valuable remedy and would cause needless inconvenience and hardship.

Suggestions as to certain further additions to the list of dangerous drugs have been received from other countries. The *veronal group* of drugs—i.e., diethyl barbituric acid and other alkyl, aryl, or metallic derivatives of barbituric acid such as veronal, medinal, dial, proponal, luminal, and their preparations or compounds—are, in my experience, drugs which commonly lead to the development of addiction. They are toxic drugs and produce cerebral symptoms and an abnormal mental condition. Death from poisoning from the barbituric acid group of drugs is relatively common. A common sequel of veronal addiction is suicide from an overdose. I have seen a number of such cases. I am strongly of opinion that this group of drugs should only be supplied on medical prescription, and that the prescription should be retained by the pharmacist as in the case of the "dangerous drugs." In other words, Sections 5 and 6 of the Dangerous Drugs Regulations, 1921, *should apply to these drugs.* addition of a drug to the "Dangerous Drugs Regulati involves many more conditions other than those of two sections, and it does not appear necessary th other conditions should apply to the veronal group It would appear desirable that such restrictions as the sale of these drugs should apply as was the case during the war, without their actual inclusion under the Dangerous Drugs Act and all that that involves. The situation might be met by the framing of special regulations by the Pharmaceutical Society under Section 1 of the 1868 Pharmacy Act.

---

* Abstract of an address to the conjoint meeting of the South-West London Medical Society and the South-West London Chemists' Association on May 5th, 1926.

*Heroin.*—It has been suggested that heroin should be abolished and its manufacture prohibited. Heroin has therapeutic effects which are not supplied by morphine or other drugs. Thus it is often more effectual in the relief of severe nerve pain. It does not cause constipation. In some cases where morphine is not tolerated, causing vomiting or excitement, heroin acts as a perfect hypnotic. For these reasons it is held that heroin should be retained as a therapeutic remedy. The dangers of addiction from its continual use must never be forgotten.

### *Illegal Trafficking in Dangerous Drugs.*

Illegal trafficking appears to be much less in this than in other countries. A certain amount of illegitimate sale of cocaine and heroin undoubtedly occurs, as is seen from newspaper reports. This mode of contravention of the law appears to be more common amongst the vicious group of addicts—i.e., those who take the drugs for the purpose of producing pleasurable sensations or vicious indulgence. This aspect of drug addiction comes under the notice of the police more often than under that of physician or pharmacist.

Mr. John Palmer Gavitt, in his recent book, states that the world production of opium is more than ten times the outside possible legitimate needs of the world. He stresses the importance of effective control of the production of raw opium so that there would not be available a large surplus for illegitimate uses. The same argument applies to coca leaves. The control of the production of the plants from which the dangerous drugs are derived is difficult since often questions of national revenue and finance are involved, and in countries such as China, where the Government is unsettled, effective control of production is impossible.

It has already been pointed out that the institution of the Dangerous Drugs Acts and their consequent Regulations arose from international action, and that the problem of drug addiction from the standpoint of this country alone was not of such grave and pressing importance as to call for the passing of special Acts for its control. We must, however, view the subject of drug addiction from an Imperial standpoint. The British Empire is world-wide in its extent and interests, and includes countries such as India where a large proportion of the plants are grown from which the dangerous drugs are derived. Great Britain, therefore, on account of its Imperial interests is vitally concerned in the problem of the control of the dangerous drugs.

Another aspect of the question must not be lost sight of. Drug addiction is a disease which is infectious, one person influencing another. Though addiction is not common in Great Britain it is prevalent in some other countries. For example, it was estimated by a special committee that in 1918 the number of drug addicts in the United States exceeded one million, and in New York City the health officer reported a prevalence of 1·8 per cent. of the population. It is thus clear that drug addiction is prevalent to a serious extent in the United States. There is a real danger of the spread of drug addiction to this country, and on this account as well as for Imperial reasons it is necessary that Great Britain should play an active part in the fight against this world menace.

### *The Regulations.*

The application of the Dangerous Drugs Acts to this country is evinced by the Regulations which have been drawn up. The Regulations of May, 1921, and the subsequent amendments were very carefully considered by the Home Office authorities, and the representations of the professions of medicine, dentistry, veterinary surgery, and pharmacy were given the fullest consideration. The Home Office authorities, amongst whom Sir Malcolm Delevigne should be specially mentioned for his devoted attention to this difficult subject, did their utmost to meet the wishes of those concerned, consistent with the effective drawing up of the regulations required by the terms of the Convention. It cannot be claimed that these Regulations are at present perfect, but they have been drawn up in a spirit of justice and fairness to all concerned. As regards avoidance of harshness of operation on the professions mentioned, and, what is of equal importance, on the addicts affected, the Regulations are a model to other countries. I know also that moderation and restraint have been shown, as far as possible, by the Home Office authorities and the Ministry of Health in carrying into effect the principles of the Regulations.

In the difficult position created by the Dangerous Drug Regulations it must be borne in mind that the object for which they were framed can only be satisfactorily attained by the loyal coöperation of the professions concerned with the State authorities. Drug addiction, to quote the words of the Departmental Committee on Morphine and Heroin, should with few exceptions be regarded as a manifestation of a morbid state, and not as a mere form of vicious indulgence. It is in this spirit that the Regulations in this country have been framed. They contrast favourably with the Regulations in America and some other countries where drug addicts are regarded as wilfully vicious persons, and are notified to the authorities before drugs can be supplied to them. Doctors even have to obtain a special licence to prescribe the dangerous drugs.

### *Application of the Acts to the Pharmacist.*

The pharmacist is much more closely affected by the Dangerous Drugs Acts than is the physician. For purposes of manufacture, import, and export, he is subjected to a very rigid control and needs a special licence. The Regulations made under Section 7 of the 1920 Act involve most careful registering of every prescription coming under their scope and of all sales and purchases. The onus of detecting forged prescriptions appears to rest with the pharmacist (Section 6 of the Principal Regulations and Section 3 of the Statutory Rules and Orders 1923, No. 312). It is stated that a prescription shall only be dispensed if the person dispensing the prescription is acquainted with the signature of the medical practitioner, registered dentist, or registered veterinary surgeon by whom the prescription purports to be given, and has no reason to suppose that the prescription is not genuine or if he has taken reasonably sufficient steps to satisfy himself that the prescription is genuine. When one considers the difficulty of deciphering the signatures attached to some prescriptions one can form some idea of the difficulty and responsibility devolving on the pharmacist.

It is a common occurrence for prescriptions coming under the purview of the Dangerous Drugs Acts to be written in such a manner that the Regulations are not fully complied with. When these are presented to the pharmacist he is put to not a little trouble and inconvenience before matters can be rectified, and the patient suffers by unnecessary delay. Sometimes questions arise which involve a very intimate knowledge of the Acts and Regulations. To quote one example: Pulv. ipecac. Co. B.P., or Dover's powder, is excluded from the scope of the Act, but a prescription of equal parts of Dover's powder and some harmless drug such as aceto-salicylic acid has been held to come within the scope of the Act—i.e., to be a "dangerous drug." Delivery to messengers of dispensed medicines adds further responsibilities to the pharmacist.

The Regulations applying to hospitals and public institutions have been framed so as to work efficiently and satisfactorily, but they nevertheless add a heavy load of responsibility and labour to the pharmacist. The pharmacist is liable to inspection of his records at any time by official inspectors, who may not have had a special training in pharmacy. In the case of medical men inspectional visits are usually carried out by medical officers of the Ministry of Health, and this considerably lessens the inconvenience caused by the inspection. It would add greatly to efficiency and also to the convenience of pharmacists if official inspections were conducted by officers who were qualified pharmacists.

Lastly, and most important to the pharmacist, is the financial sacrifice involved upon him by the Dangerous Drugs Acts. For many years he had been legally entitled to sell the dangerous drugs and their preparations under the conditions laid down in the Pharmacy Acts. In May, 1921, this right was withdrawn from him. All honour is due to the loyal coöperation of the pharmaceutical profession for their giving up without complaint a privilege and right to which they had been legally entitled.

### *Application of the Acts to the Physician.*

The physician who dispenses remedies coming under the scope of the Acts is required to keep a record of the medicines supplied by him. In the case of physicians who prescribe but do not dispense, special conditions are laid down as regards the writing of the prescription, and it must be signed with his usual signature and address. "Official forms" have not, up to the present, been ordained by the Secretary of State. A physician who prescribes dangerous drugs need not keep any record of his prescription. A physician may write a prescription for his own use (Reg. 1923, No. 577). The application of the Dangerous Drugs Acts and their regulations causes little or no inconvenience to the physician who prescribes only. All that is required of him is care in the details of the writing of his prescription. In the case of the physician who dispenses a certain amount of inconvenience is caused in the keeping of the records of those medicines which come under the scope of the Act, and these records are also liable to inspection.

In the case of the pharmacist the application of the Acts is vastly different. He is deprived of his long-standing and vested right to sell dangerous drugs and their preparations under the Pharmacy Acts. He is subjected to a number of carefully detailed regulations as regards the sale and supply of the drugs. He has to bear the onus of blame where fraudulent prescriptions are inadvertently dispensed. He is saddled with a great amount of very responsible clerical work in the keeping of records. He has to bear the trouble of rectifying matters when prescriptions are presented to him which do not comply in every detail with the Regulations. And lastly, should any infringement of the provisions of the Acts or their Regulations occur he is liable to enormous penalties.

A perusal of the penalties for offences against the Dangerous Drugs Acts (vide Dangerous Drugs and Poisons Amendment Act, 1923) is enough to cause alarm and astonishment. For conviction on indictment a fine not exceeding £1000 or penal servitude for 10 years, or both such fine and penal servitude. On summary conviction a fine not exceeding £250 or imprisonment with or without hard labour for a term not exceeding 12 months, or both such fine and imprisonment. The magnitude of these penalties is due to the recommendations of the International Convention. One cannot but feel that they are ridiculously excessive.

To sum up the application of the Dangerous Drugs Acts. To the physician they have caused some inconvenience if he dispenses his own medicine. To the pharmacist they have caused a greatly increased amount of responsible clerical work, a burden of heavy responsibility especially in the case of dispensing where fraud is attempted, and a definite financial sacrifice.

### *Conclusion*

In view of the great inequality of effect of the Acts on the medical and pharmaceutical professions it appears that it would be equitable that the dangerous drugs should only be supplied on medical prescription, and that they should not be dispensed by a medical practitioner except in cases of emergency or in rural districts where a pharmacist is not available. This procedure has been in operation in the case of insured patients since the adoption of the National Health Insurance Act and it has worked admirably. It would, I think, involve no financial sacrifice on the part of the medical practitioner and would relieve him of troublesome clerical work. The double check—viz., the writing of the prescription by the physician and the dispensing by the pharmacist—would be in the interests of the public for there would be a double safeguard against any possible error. It would be the first step towards that harmonious relationship and coöperation between the professions of medicine and pharmacy which should be arrived at in all their associations, viz.:—

The physician should prescribe and not dispense.
The pharmacist should dispense but not prescribe.

## MIND AND BODY

THE relationship between mind and body has attracted the speculations of the philosophers throughout the ages but it is only of comparatively recent times that any attempt has been made to approach the problem of the mind body relationship by submitting to laboratory examination any of the curiously complex processes involved. The asthmatic's artificial rose, hysterical contractures, and the psychic flow of gastric juice are well known instances of the influence of mind on body. Fear as an emotion can produce great bodily disturbance, and it is possible that the phrase "frightened to death" contains more than an element of truth. A better understanding on the part of the public of the underlying processes and principles governing the relationship of mind and body will help the practitioner to convince his patients and their friends of its importance. An excellent guide for the general reader will be found in a recent little book by Prof John Laird.[1] Starting from the common-sense attitude that our minds and bodies are entirely different, Prof Laird traces the evidence for the mind's influence upon the body and the more obscure general influence of bodily health upon mental function, both from the physiological and psychological points of view. Prof Laird criticises severely much of Freud's work on the unconscious, and goes on to deal with the psycho-biological theories of Rivers and other workers in the field of hysteria. Much recent physiological research has also been skilfully summarised in a few pages. The facts thus set out form the basis for various hypotheses concerning the connexion between the mind and the body, and the hypotheses considered appear to be of three essential types. "Either the mind depends on the body or the body depends on the mind or the two are independent although conjoint." The arguments for and against these various hypotheses are faithfully dealt with and the theory of parallelism between mental and neural processes which denies interaction receives much attention.

The general reader, for whom this book is primarily intended, will have difficulty in following some of the metaphysical theories considered by Prof. Laird, but those who are prepared to give patient study to this book will certainly widen their philosophical outlook.

## AMPUTATION: A LEGAL DECISION

THE *Matin* (May 11th) publishes the following report from its Brussels correspondent. A certain negro king was obliged to have a leg amputated on account of a serious accident. When the operation was over he asked for his leg back so that he might eat it. The doctor, who was a white man, refused his patient's request on the ground that cannibalism is not allowed in the Congo. The king, however, engaged a lawyer and brought the doctor and staff of the hospital before the court at Boma, insisting that they should return his property; and when the court had heard the plea it decided that the hospital must certainly restore the leg to its owner.

## THE PUBLIC SCHOOLS YEAR-BOOK, 1926

PARTICULARS of the public schools of the United Kingdom, arranged in alphabetical order, form the greater part of the contents of the Public Schools Year Book (1926, London: H. F. W. Deane. Pp. 927, 10s. 6d.). There follow entrance scholarship announcements for 1926, regulations for the entrance examinations to the universities, and brief notes on the individual universities and colleges of the United Kingdom. The rest of the book describes the various careers open to young men and the ways in which candidates for professions of all kinds can enter them. The 30 pages allotted to medicine include a comprehensive list of scholarships given in aid of medical study and will be found useful by parents with gifted sons.

## PNEUMONIC PLAGUE IN SIBERIA IN 1921.

Dr. H. M. von Jettmar, of the North Manchurian Plague Prevention Service at Harbin, has made some remarks on Pneumonic Plague in Siberia in 1921,[1] which are of interest. A Chinese coal miner of Dalai Nor, took pneumonic plague on Jan. 25th and infected a Cossack, B., who slept a night at his house. B. crossed the Argun river into Russian territory, where he fell ill on Jan. 30th and died on Feb. 2nd without medical aid. Throughout his illness he lay on his side coughing towards his room, which later was found widely fouled with sputum. All the ten soldiers who regularly slept in his hut of nights caught plague and died. B.'s sister turned up to see his corpse and was interned in the hut till all the deaths were over. She wore a mask and carried out the other protective regulations and was not attacked. B.'s sister-in-law came to see him, yet alive, on Feb. 1st, fell ill on the 4th and died on the 6th. In her smaller room there were four other persons, none of whom became infected, though her sputum was on the 6th an almost pure culture of plague bacilli. She lay on her bed behind a low partition with her face throughout to the wall, on which her sputum fell. This relation of position to infection has been noticed by Kitasato and others. At this time incubation was generally three days, but might extend to five, or even eight. Invasion was sudden. The sputum was not infectious at the very first, but soon became so, and ever more and more (more and more bacilli) as the case went on. Cases lasted two and a half to three days. Dr. von Jettmar did eight post-mortem examinations which were all much as usual though all showing a long bacillus, very numerous, in addition to the plague bacillus. It was most frequent in the subpleural connective tissue but never appeared in the sputum. Another autopsy had special interest. P. fell suddenly sick on the evening of Feb. 18th, and in the early morning went into an outhouse and hanged himself. The temperature was about −15° F., and his body was forthwith frozen stiff, thus giving special opportunity to study, six hours later, the appearances in an early case of pneumonic plague. So Dr. v. Jettmar is able to tell us that there was already advanced consolidation of the middle lobe of the right lung, and it was commencing in the upper lobe. He gives seven closely printed pages of his histological findings, but we have, we regret, only room to say that he finds no reason for supposing that pneumonic plague is primarily a septicæmia; on the contrary, he thinks it is at first localised in the air passages of the lungs. Even on the first day large areas of lung are hepatised. In the early stage there is much effusion into the alveoli of blood serum and cellular exudate, through this the bacilli are uniformly distributed, only later tending to gather on the alveolar walls. There are no bacilli in the blood vessels, but they are seen in the lymph spaces around vessels and bronchi. The long bacillus was not found in this case, only the plague bacillus; an unusual finding in this particular epidemic. In this very early stage the usual necrosis of tissue was conspicuously absent. There were no bacilli in the spleen.

## DIETETICS.

A LITTLE book [1] based upon the diagram of a "square meal," which was first published in a pamphlet for the People's League of Health, is concerned principally with the three vitamins and with protein, which form the four corners of the square in the diagram. After a short historical chapter, in which the sins of civilisation are emphasised, and a general chapter on the purpose and nature of food, Prof. and Mrs. Plimmer proceed to deal in some detail with the various deficiency diseases. Throughout they bring out their thesis that while absence of this or that factor produces a definite disease, relative absence may produce minor disturbances of health which may in turn culminate in more serious maladies such as diabetes or cancer. We would point out that eminent dietitians have protested against this view. The return to natural foodstuffs, so-called, by the population at large would probably not be an unmixed blessing despite the attractive arguments advanced in this book and elsewhere, but we may nevertheless admit that "civilisation has made it too easy to get wrong foods of all kinds." At any rate, the plea for a better balancing of the diet in the "square meal" is one which can be thoroughly endorsed, and this little book makes quite clear what this balance means.

## RECTAL FEEDING.

IT is not uncommon to consider that adequate nourishment, at any rate the best obtainable under the circumstances, is provided by an enema containing milk and egg. Mr. S. W. Cole points out, in the April number of the *Charing Cross Hospital Gazette*, that egg-white per rectum is entirely useless since the only proteolytic enzyme secreted by the large intestine is erepsin, which is normally utilised to split the peptones and polypeptides, formed by gastric and tryptic digestion, into free amino-acids, in which form they can be absorbed by the blood. The proteins of egg are therefore returned unchanged except for partial decomposition by the bacteria. The casein of milk is partly digested by its previous peptonisation to a mixture of amino-acids and caseoses, and these latter are susceptible to erepsin. Milk, therefore, probably yields an appreciable amount of assimilable protein before it is returned by the bowel. But the whole yield of protein from 6 oz. of diluted peptonised milk is not more than 1 g., and the milk cannot be used stronger because of the slow action of trypsin on undiluted milk. Now the recognised standard figure for adults is 100 g. per diem, and the administration of 1 g. of protein in a nutrient enema, even if four are given daily, is manifestly futile. Mr. Cole suggests the use of a broth which he has used in his Cambridge laboratory for many years. It is made by shaking 200 g. of commercial casein with 2 litres of water and adding caustic soda to dissolve the casein and bring the solution to $pH = 8{\cdot}1$, the optimum reaction for trypsin. It is then incubated with strong tryptic extract, and some antiseptic such as chloroform or toluol, for 8 to 14 days at 40° C. The resulting filtrate is stable and contains about 9·5 per cent. of digested protein, about 50 per cent. of which is in the form of free amino-acids. Thus, if four enemata of this solution were given daily, about 64 g. of protein would be absorbed. Mr. Cole urges the trial of this solution in surgical or obstetrical cases requiring rectal feeding, and also in some forms of anæmia where the failure of digestion or absorption gives the intestinal bacteria more than their normal chance of destroying the amino-acids or converting them into toxic compounds. The free amino-acids thus provided might be absorbed before the flora of the bowel had time to attack them.

## THE TRUTH ABOUT BORSTAL.

THERE is a point of view from which Borstal institutions are regarded as part of a degraded and brutal system; whilst from another they appear to be organisations managed by sentimentalists for the purpose of coddling young criminals who would be better dealt with in the way that all right-minded people would deal with all such scoundrels. Stimulated by these contrary views, Mr. Moseley [2] set out to find what the institutions really were and what they did. He familiarised himself with the procedures by which offenders were sent to them, he sought out those who had the management of the system, and he visited the different establishments to obtain first-hand information from their inmates. The result is a simple account of the development of the four institutions at Rochester, Feltham. Portland, and Aylesbury, with their achievements in the reclamation of social misfits before they became irreclaimable. He concludes that there has been a vast improvement in the Borstal system in recent years, that it is now sensible and humane, and that the difficult problem of the delinquent adolescent is being fairly well met though there remains room for further reforms, especially in selection and classification. The book is well illustrated and its balanced presentation of facts justifies its title.

## TROPICAL HYGIENE FOR SCHOOL CHILDREN.

"In the tropics," says Dr. Mary Blacklock, of the West African Medical Service, "we may still see a schoolboy, ignorant of the cause of malaria, clasping a book of Euclid close to his enlarged malarial spleen, and may still hear a learned B.A. discoursing eloquently on the philosophy of John Stuart Mill, the while mosquitoes breed in the roof gutters of his house and rats scamper over the refuse heap in his yard." In their attempts to promote the public health sanitarians are constantly thwarted by the ignorance of the people, and it is to meet the need for simple instruction that Dr. Blacklock has written "An Elementary Course in Tropical Hygiene," of which the first part has been published for the Tropical Diseases Bureau by John Bale, Sons and Danielsson, Great Titchfield-street, London, W., at 1s. (pp. 44). Dr. Andrew Balfour contributes a preface and we agree with him that this primer is well adapted to the needs of the child mind. It is in two divisions. The first is a series of lessons on the things which keep the body healthy and things which make it unhealthy. The second is in story form and is told in such a way as to interest any children who can understand simple English. Dr. Blacklock has added drawings of some of the principal enemies of man, and the handbook will certainly be useful in the hands of any reasonably intelligent teacher.

## ROYAL MEDICAL BENEVOLENT FUND.

AT the last meeting of the Committee 30 cases were considered and £188 voted to 28 applicants.

Daughter, aged 49, of M.D. Edin. who was a retired colonel in the A.M.S. and died in Devonshire in 1919. She has tried to maintain herself, but owing to ill-health and bad eyesight has had to give up work and is now living on her capital which only brings in £17 per annum at the present time. Friends gave £12 and she received £3 10*s*. as a lady help for two months. Voted £20 in four instalments.

Daughter, aged 70, of M.R.C.S. who practised in Norfolk and died in 1868. Applicant has worked as a children's nurse for 24 years; since as a housekeeper until recent illness. Now unable to do anything. Is applying for the Old Age Pension. Only income £2 17*s*. 6*d*. per annum. Lives with a friend who is unable to keep her. Voted £26 in 12 instalments.

Daughter, aged 62, of L.S.A. who practised in London and died in 1914. She has a small nursing home, but owing to the bad condition of the house is unable to get patients. Has borrowed money to meet rent of which £6 2*s*. is still outstanding. Received from patients £103. Rent £56, rates £20. Voted £10.

Widow, aged 55, of L.S.A. who practised in London and died in March. Applicant's late husband was over 80 years of age and needed constant attention, which precluded the applicant from earning. She is now looking out for a post and the Fund granted her £15 to meet outstanding rent and to carry her on whilst seeking work.

Widow, aged 40, of M.B. Glasg. who practised in Wales and died in 1924. Asks for help with her son, aged 15, who through the influence of friends is now apprenticed to a firm of engineers. This boy is now in charge of a guardian as the applicant is lying seriously ill in an infirmary. Guardian voted £26 in 12 instalments towards maintenance of the boy.

M.R.C.S. Eng., aged 56, who was in the A.M.S. and owing to mental breakdown will be unable to work again. Relations subscribe to the support of the applicant but one has recently retired from his profession and is unable to continue his contribution. Fund voted £30 in 12 monthly instalments in May, 1925, and the amount was renewed at this meeting of the Committee.

Daughter, aged 53, of M.R.C.S. Eng. who practised on the East Coast and died in 1908. Very delicate and unable to work. Lived with her mother (who was a pensioner of the Fund) until she died in 1922. The applicant has received £93 from the Fund since 1920 and her grant of £18 was renewed.

Daughter, aged 44, of M.R.C.S. Eng. who practised in Yorkshire and died in 1906. Has been an invalid since the death of her father and is looked after by a nurse who receives 15*s*. a week for her maintenance. A brother-in-law has helped to keep her at the home, but owing to his inability to find all the money the Fund was asked to help. £175 has been granted since 1919 and the grant of £26 in 12 instalments renewed.

Subscriptions may be sent to the Hon. Treasurer, Sir Charters Symonds, at 11, Chandos-street, Cavendish-square, W. 1.

# The Linacre Lecture

ON

# DISEASE IN THE LIGHT OF EVOLUTION.

*Delivered at Cambridge on May 6th, 1926,*

BY SIR F. W. ANDREWES, O.B.E.,
M.D. OXF., F.R.S.,
PROFESSOR OF PATHOLOGY IN THE UNIVERSITY OF LONDON.

THERE was published last year a book, written by many well-known authorities, entitled "Evolution in the Light of Modern Knowledge." It dealt with evolution as it relates to no less than 13 different subjects, covering most of the natural sciences, and ranging from the birth of the universe to psychology and religion. But it contained no chapter on evolution in relation to pathology, and when I received the great honour of an invitation to deliver the Linacre lecture this year it seemed that here was a subject ready to hand, and I resolved to do my best to supply the missing chapter.

If the shade of Linacre hovers over the lecture which he founded so long ago he may be puzzled to know what my title means. But he ought not to complain of my choice if he can be persuaded that a principle which has transformed and vivified every branch of natural knowledge can render the same service to the subject to which he himself dedicated so much of his life. A right understanding of the processes of disease lies at the very root of medicine, and it is the great merit of the doctrine of evolution that it stimulates us not only to ascertain the facts of Nature but to understand them better, by tracing, so far as we may, the manner in which they have come about.

There is no need, in Darwin's own university, to defend the doctrine of evolution, and I am content to accept his fundamental conception of natural selection as the chief agent in bringing about the upward progress of life. Most of us can agree that, in the struggle for existence, those individuals or races have had the best chances of survival which have become best adapted to their environment and have proved most capable of adaptation to changes in their environment.

### THE ADAPTATIONS TO ENVIRONMENT.

Now, if one were asked to define health, it would be difficult to do so except in terms of adaptation to environment. The healthy body is one which is not only perfectly adjusted to its surroundings, but is capable of adjusting itself, within reasonable limits, to the circumstances of a rapidly changing environment. Disease is a condition in which the body has fallen, in lesser or greater degree, out of harmony with its surroundings; we may feel only discomfort and inconvenience, but in its graver forms life itself is endangered.

Success or failure in adaptation to environment is thus a link which connects the struggle of the race for existence with health and disease in the individual. We may be prepared to find the relation a close one, and the more we study the matter the closer it seems. The relation is reciprocal; there can be no doubt that disease has profoundly influenced the march of evolution, and equally none that many of the processes of disease, as we see them to-day, have not only been improved and modified, but owe their very origin to the survival of successful modifications during the course of evolution in the past.

Disease constitutes no small item amongst the adverse circumstances against which the struggle for existence has been carried on. It may arise from within, in the form of unfavourable morphological, physiological, or chemical variations in the individual, which have tended to weed out their unfortunate subjects in competition with others. Much more often diseases arise from without. Adverse climatic conditions, inadequate nutrition, wounds and injuries, and, above all, invasion of the body by parasites of all kinds, especially by micro-organisms—these are some of the troubles against which the body has to contend, and in face of which the weaker goes to the wall. Of all the teeth in the terrible comb with which Nature sorts out the inefficient, disease is one of the most formidable. It may well be that, in the past, whole races of animals have been swept away by diseases against which they were unable to establish resistance. There is no actual proof of this, though we know from the scanty evidence of fossil bones that disease is of vast antiquity. Even in modern times we have witnessed the extermination of races of mankind by the infections which contact with civilisation has brought in its train.

Our ideas of disease are naturally based upon what we see of its processes in the more highly organised plants and animals, and especially in man. But if we take a wider outlook we shall realise that diseases must necessarily have become more numerous and varied in the course of evolution. The more complicated and elaborate the mechanisms by which highly specialised organisms secure their adaptation to environment, the more liable are they to get out of order. A chronometer can suffer from a greater variety of defects than an hour-glass. If we are to accept the idea of evolution in disease and its processes we must be prepared to start from a more primitive state of affairs than we see to-day. Search in the records of the past for evidence of the beginnings of disease is largely fruitless; fossil records are not only casual and imperfect, but practically limited to the hard parts which are affected only by few diseases. Much more promising is comparative pathology, for here we can directly study the processes of disease in lower animals and bring them under experimental control in the laboratory. It is in this manner that we may most surely hope to unravel the problems of the evolution of morbid processes, following the lines so brilliantly laid down by Metchnikoff in his studies of inflammation.

### THE EVOLUTION OF DEFENCE PROCESSES.

The subject to which I wish to direct attention in this lecture is the manner in which the animal body has learned to defend itself against injurious agencies, believing, as I do, that the processes of defence have been gradually developed and perfected in the course of evolution.

The primitive notion of disease was that of some personal devil entering into the body, to be expelled by charms and exorcisms. This is true of some diseases if we choose to regard an infective microbe as a personal devil, but even so it is not wholly true, for the devil may enter yet no disease result, as we see in many bacterial carriers. The phenomena of disease arise when the body takes steps to expel the intruder. Even up to recent times disease was held to be an abnormal state into which the body fell. But now that we have a clearer apprehension of the causes of disease and of the nature of its manifestations, we realise that the latter for the most part represent reactive processes by which the body is attempting to overcome the hurt that is being done. We recognise definite "disease processes," many of which are in the long run beneficial to the organism. It is an evil that a tissue should become inflamed and that the body temperature should rise in an acute infection, but it is a lesser evil than that the infecting agent should overrun the body unchecked by any antagonistic mechanism. The recognition of inflammation and fever as beneficent reactions means a change in the point of view from which we attempt treatment.

### *Inflammation.*

Of all the various processes of disease that of inflammation is the one which can best be followed in its evolution, chiefly owing to the patience and genius of Metchnikoff in following the response to from the most lowly forms of life to the

We cannot dissociate the reaction to injury which we call "inflammation" from the actual repair of injury to which it commonly leads up. It is true that acute inflammation and repair are not the same thing, for either can occur without the other; but acute inflammation shades gradually into chronic, and chronic inflammation is so closely associated with repair that we cannot consider them apart.

The epiblast and hypoblast are chiefly concerned in the formation of specialised tissues of epithelial nature, and this is also true of the mesothelial division of the mesoblast, which, besides giving rise to the voluntary muscles, forms the urinary and reproductive epithelium. The mesenchyme is that other division of the mesoblast which is responsible for all the connective tissue framework of the body and for the vascular and lymphatic endothelium. It is not to be denied that many tissues of epiblastic, hypoblastic, and mesothelial descent possess, even in adult life, considerable power of regeneration; they can undergo mitosis and multiplication to replace cells which have been lost. But they do this without the necessary intervention of anything that we can call inflammation, though we witness the process often enough in the closing stages of inflammatory repair, as when epithelium grows over a healing wound. But the point which I wish to emphasise is that inflammation, whether acute or chronic, is essentially a process carried out by tissues of mesenchymal descent.

We see this clearly brought out by the studies of Metchnikoff, and those who have not time to read these in the original will find them succinctly summarised by Adami in the chapter on inflammation in Allbutt and Rolleston's "System of Medicine." The mesoblast is seen in its most rudimentary form in the larval echinoderm at the gastrula stage; it consists here of a few stellate or wandering cells in the cavity between the epiblast and hypoblast. If a spicule of any sharp substance be introduced into this cavity, as might easily happen naturally, the wandering mesoblastic cells are seen to approach the foreign body, and, should it be too large to be enclosed by any one of them, several apply themselves to it and fuse into a syncytium, thus rendering it harmless to the more important cell layers.

By no stretch of the imagination can we call such a process inflammation; it is just a protective reaction on the part of the wandering mesoblast, definitely advantageous to the organism. Yet it would seem that from such a simple thing as this the elaborate reaction of inflammation in the higher vertebrates has step by step been evolved, and some of the steps can be followed.

The rudimentary mesoblast of the echinoderm becomes more complex as we pass up the animal scale. In worms and crustacea the wandering mesoblastic cells of the body cavity are now definitely of the nature of primitive leucocytes, eventually becoming differentiated into leucocytes of more than one kind. Metchnikoff showed that these early leucocytes already exhibit the capacity for engulfing and destroying intruding microbes—the beginnings of that defence which I shall have to speak of in more detail later in this lecture. In the earthworm the spores of parasitic gregarines may thus be destroyed, and in the small crustacean, *Daphnia*, a similar defence against a parasitic yeast is seen. Further, the repair of small injuries to the carapace of the crustacean is found to be associated with an accumulation of leucocytes beneath the seat of injury. But amongst invertebrates the reaction to injury or infection seems at the most to consist in a phagocytic activity on the part of the primitive leucocytes, combined with a capacity for the regeneration of lost parts, to which I shall refer a little later. It is noteworthy that the vascular system, which is developed in some invertebrates, takes no share in the process, and, indeed, it would seem difficult for it to do so, since it rarely forms a closed system. The concept of inflammation is so closely associated in our minds with active vascular changes that some pathologists have denied the right of the reactions I have so far mentioned to be regarded as in any sense inflammatory. All that I am concerned to insist on is that we have here the germs of a process which was capable of developing, with better facilities, into what later became inflammation.

### *The Rôle of the Vascular System in Defence.*

The great forward step which was destined to revolutionise the response to injury is to be found in the development of a closed vascular system under vasomotor control, already present in the lowest vertebrates. Consider for a moment how the vascular system can aid in defence. It can bring to an injured region an increased supply of blood, not only conveying extra nutriment but an added number of leucocytes. Moreover, it can do these things promptly; the leucocytes, instead of having to walk, can go by train. Compare, in man himself, the sluggish nature of the reaction to injury in a non-vascular tissue such as the cornea with the rapid reaction seen after similar injury to a vascular tissue; the first takes 24 hours for its development, while in the second the process may be well advanced in half an hour. Nor is this all, for a closed vascular system renders possible a new feature in defence—namely, the mobilisation of the body fluids. The outpouring of the fluid elements of the blood into a damaged area fulfils many purposes: bacteria and their products or other chemical irritants are flushed away, fibrin can be deposited to circumscribe the spread of mischief, while the antibodies carried by the plasma can antagonise bacterial poisons and destroy the microbes themselves. The surgeon knows well what a change takes place in a foul wound which has dried up when he can succeed in re-establishing a free flow of fluid from the vessels.

It is little matter for wonder that Nature has exploited the blood vascular system to the utmost in the improvement of the processes of defence and repair, and to such good effect that we see the vascular changes dominant in the process of acute inflammation in the higher vertebrates. Nevertheless, I think we should err if we defined inflammation in terms of the vascular changes, for the vessels, after all, are only a means to an end. The central features of the process, to which everything else is subservient, are the outpouring of the fluids of the blood and the emigration of the leucocytes into the damaged region. It is the wandering mesenchyme which does the chief work, as it did far away back amongst the invertebrates, though the mechanisms by which it is brought into action are improved out of all recognition. Surely it is not too much to say that we can here trace the evolution of one of the most important morbid processes from a simple beginning up to full development.

### *Potentialities of the Tissues.*

If it is true that acute inflammation is essentially a mesenchymal reaction, this is even more obvious in chronic inflammation and repair. In considering the repair of tissues it will be found that the march of evolution has pursued a somewhat different course from that seen in acute inflammation. The lower we go in the animal kingdom the more extensive and complete do we find the capacity for the regeneration not only of tissues but of whole portions of the body. The higher we go the more restricted does the capacity become. This is a consequence of the law which seems universal in nature, that specialisation of function entails loss of more primitive faculties. The highly specialised workman in an industrial community can do his own job supremely well, but if he loses his employment he cannot turn his hand to anything else; he is no longer a handy man able to earn his living at whatever task presents itself.

The fertilised ovum and the blastomeres resulting from its first few segmentations possess the power of giving rise to all the tissues of the body; they are what Barfurth called "totipotential." As the development of the embryo proceeds, and the germinal layers are formed, their cells lose something of this primal capacity; they become "pluripotential" and can give rise only to certain kinds of tissue. Finally, as the definitive tissue rudiments are laid down, the possibilities of each kind of cell become further sorted out, till it becomes "unipotential"—capable of giving rise only to one kind of tissue. Only the germinal epithelium retains the full heritage of the species.

If, now, we follow out this conception in the evolution of the animal kingdom, we find the totipotential character present to some extent even in the tissues of the adult amongst the lower invertebrates. If a hydra is cut into a number of pieces, each can regenerate a complete animal. A lobster can grow a new claw to replace one which has been lost, as good and complete as the original though for long smaller than its fellow. But the power of reproducing lost parts becomes reduced as we pass up the animal scale, and even in the lower vertebrates is very imperfect. A lizard can grow a new tail, but it is not a good tail in comparison with the one which has been lost. In mammals there is no such power. All that remains is a unipotential capacity for compensatory hypertrophy in virtue of which, when an organ is removed or seriously damaged, its fellow, or any portion of the organ which may have been left behind, undergoes an increase in size enabling the work of the lost tissue to be carried on. In the individual tissues of the higher mammals, the more specialised the cell the less, as a general rule, do we find its capacity for regeneration. The most highly specialised cells, such as the central neurons, never regenerate. Cardiac muscle, though it may undergo hypertrophy in response to physiological needs, is never replaced when lost, and ordinary voluntary muscle makes only the feeblest efforts at regeneration. *Almost the only instance of a specialised epithelium* with noteworthy powers of regeneration is that of the liver. On the other hand, the unspecialised epithelia of the body surfaces are regenerated with ease.

The higher animals, however, enjoy some compensation for this loss of universal regenerative power. As it recedes in the higher tissues it becomes exalted in the lower, and more or less concentrated in tissues of mesenchymal origin. Modern researches indicate that the mesenchyme, having in the course of fœtal development furnished all the supporting tissues of the body, persists also throughout life as a piece of permanent machinery for repair. Whereas acute inflammation is a response on the part of the more active and mobile of the mesenchymal elements, carried out mainly by the intermediation of the vascular system, chronic inflammation and repair are brought about by the slower activities of another set of cells of primitively similar origin.

The nature of the familiar small, round-celled infiltration in chronic inflammation has been elucidated in recent years by a number of workers, including Marchand, Maximow, and others. Although in certain details all are not in complete accord there is a general consensus of opinion to the following effect. When, in the course of embryonic development, the mesenchyme has given origin to fibrous tissue, bone, cartilage, and other supporting tissues, the cells thus specialised have fulfilled their normal destiny, and if they have occasion to multiply in later life they give rise only to other cells of like kind. But a large number of mesenchymal cells are not thus used up, remaining in their primitive embryonic condition throughout life, and retaining much of the pluripotential capacities of the original mesenchyme. These wandering or sessile mesenchymal cells are universally distributed throughout the tissues of the body and have been described under many names. The term now in common use for them is that of "histiocytes." They are recognisable by their marked capacity for vital staining and their function is that of a diffuse "organ," the retention by which of its embryonic potentialities enables it to undertake the work of repair when and where this is needed. The function is restricted to the provision of fresh supporting tissue; we never see new epithelium produced in this way. In practice we find that wounds of almost every tissue and organ heal by a process of chronic inflammation which results mainly in white fibrous tissue containing a few blood-vessels. An exception lies in the repair of bone which in all favourable cases is by a new formation of true bone. But the pluripotent nature of the histiocytes is sometimes manifested by the formation of true bone as the result of chronic inflammation in other situations. In old blind eyes a plate of bone sometimes forms at the back of the globe, and bone is not rarely to be found in arteries which are in a state of advanced degeneration. Myositis ossificans is a well-known example of bone formation in voluntary muscle and I have known plates of true bone to arise in the subcutaneous tissue.

Thus, in chronic inflammation and repair we see the inevitable loss of regenerative power which attends the evolution of highly specialised tissues well compensated by a highly developed power of repair on the part of the mesenchyme.

### FEVER IN THE LIGHT OF EVOLUTION.

Let me now turn to another pathological process—fever. Here, indeed, we can only infer the probability of an evolutionary development; we cannot follow it step by step, as we could in inflammation.

From a physiological point of view the development *of the power of so regulating the temperature of the* body as to render it independent of changes in the temperature of its surroundings was an immense step in advance. The faculty probably appeared in late secondary times when birds arose from reptilian stock, but we cannot imagine it as arising other than gradually. Even amongst "cold-blooded" animals instances are to be seen in which a temperature can be maintained some degrees above that of the environment. When once the regulating power was fully developed, each species of animal must have learned, by a process of natural selection, what bodily temperature best suited its size and general activities and have adopted this as its normal temperature. Man has a norma some degrees below that of many mammals, while the normal temperature of small birds is so high as to be incompatible with human life.

The maintenance of a constant temperature rests on a due balance between heat production and loss. The ultimate presiding mechanism of regulation is even to-day not located with certainty; there is supposed to be a chief thermotaxic centre in the central nervous system, governing certain lower centres. That there is an extra-cerebral hormonic influence on the part of the thyroid-adrenal apparatus seems also probable. The precise physiological mechanism of heat regulation does not concern me at the moment; I only want you to envisage the maintenance of a constant temperature as an incessant struggle between the body and its surroundings.

Although the body is habitually successful in this struggle, it is not so in all circumstances. Just as a man may be frozen to death from prolonged exposure to severe external cold, so his temperature may rise to a fatal height from exposure to great heat. There are extremes of external heat and cold which are too severe for the thermotaxic mechanisms to cope with, strive as they may. Again, these mechanisms may be put out of action by gross injury, as in cerebral hæmorrhage, or by some profound poisoning, as in the uncommon cases of hyperpyrexia which may occur in ordinary fevers. The reason why thermotaxic paralysis sends the temperature up and not down is that heat production in the body is always potentially in excess.

Convenient general terms for temperatures below and above those normal to the body are "hypothermia" and "hyperthermia." The instances of hyperthermia which I have just mentioned are cases in which the regulating mechanisms fail to act either because they are injured or have been set a task too great for their powers. They are cases of "simple" hyperthermia in which the body is still [illegible] keep the temperature down, as is [illegible] flushed skin, sweating, and prostratio

I have felt obliged to labour this point, because when we turn to true fever we find the *conditions very different. True fever stands apart, by* common consent, as a special form of hyperthermia, differing in important respects from the simple form. There is a difference in the cause; with trifling exceptions fever is always due to an infection of some sort. *There is a difference in the mechanism;* while the temperature is rising in true fever loss of heat is checked by vasoconstriction of the cutaneous vessels; the patient feels cold and thermogenesis is actually increased by involuntary muscular shivering. One cannot resist the impression that the body is raising its temperature on purpose. Further, the departure from a normal temperature is not indefinite; in heatstroke or hyperpyrexia the temperature, unless artificially controlled, goes on rising to a fatal height, *but in true fever it rises to a certain level and seems* then content. Regulation of temperature is not abolished but altered; there is a daily fluctuation, often a considerable one, but it is about a new and higher level. The body seems to resent any outside efforts to bring its temperature down; this can, indeed, be done with baths or antipyretic drugs, but the effect is temporary and the fever soon comes back to what it had been before. Only when the cause of the fever has ceased to operate, when the infection is overcome, does the temperature come down of its own accord.

How are we to interpret these curious facts? Some *have represented the condition as a mere weakening* of normal temperature regulation. It may be conceded that, in fever, regulation is more unstable than in health, but such an explanation does not enable us to understand the purposeful manner in which *the body sets about raising its temperature.* Most pathologists are now willing to admit that true fever, as distinguished from simple hyperthermia, is a deliberate reaction of the body, serving some useful end in cases of infection sufficient to counterbalance its evident evils.

To establish the hypothesis that fever is a beneficial reaction one must be in a position to indicate some prima facie evidence that benefit does, in fact, arise, and there is such evidence, both clinical and experimental. *It is a matter of clinical experience that,* given an infection of tolerable severity, those patients who exhibit marked fever do better than those who fail to do so. It seems actually better for a case of acute lobar pneumonia to have a temperature of *104° F. than one of 101° F.* Apart from the rare cases of hyperpyrexia in which temperature control is wholly lost and we are compelled to bring the temperature down to save the patient's life, the balance of clinical evidence shows that it is wisest *to leave the fever, as such, to run its natural course.* Anything that we can do to help the patient to overcome his infection is all to the good, but to attempt to lower the temperature by antipyretic drugs does not appear of much service.

As regards experimental evidence, it is known that artificial cooling renders warm-blooded animals more susceptible to infections with such bacteria as anthrax and streptococci; a chill is often the apparent cause of pneumonia in man. Conversely, artificial hyperthermia has been shown to exercise a favourable influence on the course of infection in animals. Walther was unable to produce a general infection with the pneumococcus in hyperthermic rabbits, though in the normal animal this readily occurs. Filehne found that in warmed rabbits streptococcal infection ran a more pronounced, rapid, and favourable course than in cooled animals. It is not, indeed, to be supposed that, even in high fever, *the temperature* approaches that fatal to the invading bacterium, but every microbe has an optimum temperature, above which its higher physiological activities become impaired. Fever may thus help, at least in a contributory manner, towards overcoming an infection.

If we accept such a view we are almost bound to believe that, like inflammation, fever has been developed and perfected in the course of evolution. It would seem to be a specialised modification of temperature regulation, arising in animals in which such regulation has already reached a high stage of development. We know nothing of a rise of temperature in cold-blooded animals in response to infection.

## THE EVOLUTION OF INFECTIVE DISEASE.

This brings me to what is, perhaps, the most interesting part of my subject—the evolution of infective disease. This condition is undoubtedly of immense antiquity; the scanty fossil records, summarised by Moodie in his little book on "The *Antiquity of Disease,*" indicate the existence of caries, necrosis, and suppuration in connexion with bone amongst the giant reptiles of mesozoic times and probably even earlier. The evolutionist who wishes to speculate on the origin of infection has, therefore, *plenty of time at his disposal.*

The subject divides itself naturally into two parts. We have to trace the origin of the parasitic mode of life and of the special attributes which it necessitates; on the other hand, we have to consider the development of the faculties by which the host endeavours to keep the parasite at bay. The parasite is the attacking party and it is logical to consider its evolution first, but the problems of attack and defence must from the beginning have gone hand in hand and been originally much simpler than they now are. It is reasonable to trace back the parasitic habit to commensalism or symbiosis, in which two creatures live harmlessly together, often to their mutual advantage. Parasitism begins when all the benefit of the arrangement goes to one of the parties, while the other is usually in some degree injured by it. We see in Nature every degree of parasitism from instances in which the habit is transitory and unessential up to those in which it is fixed and obligatory.

We do not find amongst parasitic microbes those degrees of morphological degradation which are the rule amongst the higher animal parasites; indeed, they differ very little in outward appearance from their non-parasitic allies. Lack of time forbids me to attempt any discussion of the evolution of the larger animal parasites, profoundly interesting though the subject is. I regret this the less because, however remarkable the life-histories of parasitic worms and insects may be, no corresponding interest attaches to the defence of the host, which in most cases seems passively to suffer the presence of the parasite without any noteworthy effort to get rid of it. It may be that this is because the troubles arising in the host from the larger parasites are mainly mechanical in their nature, rather than toxic. *Far otherwise is it with* microbic parasites, at whose invasion the body expresses its resentment in a variety of ways, familiar as the signs and symptoms of infective disease, as well as in the more cryptic methods revealed by *immunological study.*

### *The Parasitic Habit.*

I turn, therefore, to the evolution of the parasitic habit amongst micro-organisms. Twenty years ago, in the Horace Dobell lecture before the College of Physicians, I put forward the stages by which I believed this evolution to have taken place, and I *do not wish to recant anything that I then wrote.* There are three modes of life open to such organisms as bacteria. They may subsist in typical vegetable fashion on simple mineral foods; they may subsist, like most other fungi, on dead organic matter; they may attack the living animal or vegetable body and feed on the living tissues or fluids. Fischer coined the terms "prototrophic," "metatrophic," and "paratrophic" for these modes of subsistence; it is more usual to speak of the two last as "saprophytic" and "parasitic." Again, a bacterium may grow best, or even exclusively, at the ordinary temperature of air or water; or it may have its optimum temperature *at about that of a warm-blooded animal,* growing only feebly at air temperature; a few bacteria grow best at very high temperatures, fatal to most forms of life. Fischer has coined the convenient terms "psychrophil," "mesophil," and "thermophil" for such temperature requirements, and it is noteworthy that a given bacterium almost always falls clearly into one of the three groups, though there is some overlapping.

Bacteria are of extreme antiquity and have been recognised with considerable certainty in rocks of early palæozoic date. Primitive bacteria must have been prototrophic and psychrophil. How and when they, with other fungi, adapted themselves to a saprophytic mode of life we do not know, but it was very early for, even in palæozoic times, mould fungi and bacteria appear to have invaded dead bones where they have been fossilised.

The next step must have been association with the bodies of higher animals for the sake of the abundant nutriment there to be obtained, and this, too, must have been early and long before warm-blooded animals came into existence. The advantages to the microbe of this association or symbiosis, are obvious; the cutaneous and mucous surfaces of the host, and especially the contents of the alimentary canal, form an ideal habitat for saprophytic micro-organisms. So long as such association was with the body of cold-blooded hosts no fundamental modification was requisite in the life of the microbe, but when warm-blooded animals arose such symbiosis demanded one important change. The microbe was compelled to adapt itself to the temperature of its host, and thus we may conceive mesophil bacteria and animal parasites to have been derived from the primitive psychrophil forms. All those bacteria which we now find to grow best at body temperature may be assumed to be naturally saprophytic on birds or mammals. In the bacteriological examination of air or water, the only organisms to which we pay serious attention are the mesophils, which we regard as an index of pollution from animal sources.

One disadvantage of the mesophil habit is the precarious nature of transfer from one host to another, since these saprophytes are continuously being voided from the body. But the retention of some power of multiplying at air temperature and the faculty of resisting drying for a certain time enable a sufficient number to reach a new host so that the life of the species is not endangered. The endospores of many bacilli and the cysts of intestinal amœbæ greatly facilitate the process of transfer. It is only when we come to the more delicate of the strict parasites that transfer can only be accomplished by actual contact of the two hosts, as we imply by the term "contagious disease."

The final stage begins when such harmless saprophytic associates of the body are no longer content to inhabit its surfaces, but strive to enter the blood and tissues and maintain themselves there. I have already alluded to evidence that even this parasitic process is of great antiquity, preceding the evolution of warm-blooded animals, and we know that such parasitic invasion occurs to-day even in lowly invertebrates. The struggle for existence has always been so keen that every nook and cranny which could be made to support life was liable to be invaded. Given a horde of saprophytes infesting the surfaces of the body, it is evident that there are ample opportunities for deeper intrusion, whether through chance wounds, or by absorption from the intestine. The mesenteric glands are seldom sterile and there is experimental evidence of sparse infection of the liver by the portal blood-stream.

The host, which tolerated a harmless saprophytic association, was now bound to take cognisance of such unwelcome intruders. Before adequate means of defence had been evolved the invasion was presumably not hedged about by the difficulties which beset it to-day. But the host had to defend itself, and, as I hope to discuss in a little while, it has been in the long run successful in keeping most of the would-be invaders at bay. One has to speak, for the sake of brevity, as if the opposing parties were conscious agents, but you will understand me to mean only that natural selection favoured such chance variations as enabled the fittest to survive. When once the host had begun to defend itself, we must conceive of counter-moves on the part of the parasite, designed to break down the defence, and we must imagine a number of such devices, arising one after the other, as new defensive methods were evolved by the host. The production of substances poisonous to the cells of the host has been one such device; amongst the most successful parasitic microbes are those which form toxins inimical to the tissues of the body. There is no doubt that the thick capsules which some bacteria form when growing in the body represent a sort of protective shield for the parasite. Bacteria appear also to produce substances which poison the leucocytes sent to do battle with them. The "aggressins," described by Bail, are substances produced by bacteria in the body, not in themselves poisonous, but in some unknown way assisting the bacterial attack. All these properties of a successful invader are summed up in the convenient term "virulence." We have to envisage the struggle as one in which both parasite and host are each constantly endeavouring to immunise itself against the other, and the result is an unstable equilibrium in which a very little turns the scale.

It will, I think, be generally agreed that parasitic bacteria have been evolved from the regular saprophytes of the body, by chance variations which enabled them to take advantage of accidental introduction into the body proper and thus conquer a new field. This they have succeeded in doing by developing active means of aggression or passive shields of defence. In a few organisms the process has been so successful that they have permanently adopted the parasitic life and can no longer live in any other way. Others are facultative, not obligatory parasites; they habitually live on the surfaces of the body as saprophytes and only invade it in specially favourable circumstances.

### *Parasites and the Alternation of Hosts.*

There exist, however, certain diseases in which the evolution of the parasite cannot have followed the course I have just outlined, those, namely, in which the parasite undergoes an obligatory alternation of hosts and in which the warm-blooded animal is always infected by the bite of an insect. Such diseases are due either to protozoa or protista, never to bacteria. The sexual phase of the parasite is passed in the insect which must thus be the primary host. In the alimentary canal of insects there are found many protozoa or protista closely allied to the forms pathogenic for man. In some cases the association with the insect seems to be one of symbiosis, and the parent insect regularly hands on the symbiont to its offspring by systematic infection of the ovary; this remarkable phenomenon is seen in some of the instances in which there is a secondary life-cycle in the vertebrate, notably in the case of ticks.

In the human diseases here under discussion we must seek the evolution of the parasite not from the ranks of human saprophytes, but from the fauna which normally inhabits biting insects. Such microbes, at first accidentally transferred by the insect's bite or by the defæcation which commonly follows the meal of blood, must have explored the new possibilities lying before them in the same way as I have suggested in the case of the saprophytic bacteria. Doubtless there were many failures, but some succeeded in developing a secondary asexual life-cycle in the blood or tissues of the new vertebrate host. The precarious nature of transfer from the latter back to the insect is met, as often in such instances, by the copious asexual multiplication taking place in the vertebrate host. For the vertebrate cycle is only secondary; to secure the perpetuation of the race the parasite must pass back again to
insect for its sexual cycle. The alternation
insect and warm-blooded animal involves
adjustment of temperature requirements, and
be noted that the diseases in question are in

those of tropical climates where the difference in temperature between mammal and insect is relatively small. As a hypothesis, such a mode of origin of these human diseases is not to me incredible. The complex life-history of the malarial parasite is, it is true, not easy to explain in detail, yet, if we are to explain it at all, it must, I think, be on some such lines as I have ventured to suggest.

### DEFENCE AGAINST MICROBIC INVASION.

I must turn, lastly, to the evolution of the processes of defence against microbic invasion on the part of the host. So long as associated microbes were content to dwell on his surfaces and to subsist on his waste products, no defence was needed beyond a local tolerance of guests which did little harm. But when once they attempted true parasitism the question of defence became urgent, for the life of the host was at stake.

It is fairly certain that the primitive defence lay with the wandering mesoblast, and was phagocytic in nature, since this is already observed to be the case in lowly forms of metazoal life, and seems, indeed, the only mode of defence in invertebrata. Phagocytosis is the normal method of feeding in an amœbæ; free living amœbæ subsist largely on bacteria which, having been engulfed, are disposed of by intracellular digestion. The retention of a power of this kind by the undifferentiated mesoblast of the simpler metazoa offers a natural explanation of primitive phagocytic defence and may be held to be an illustration of the economy of Nature in adapting to a new use a function which originally served a more primitive purpose. There is very little difference between the engulfing and digestion of a bacterium by an amœba and by the polymorphonuclear leucocyte of man; only, in the latter case, the leucocyte is acting in the service of the whole body. There is, indeed, another difference, but it is probably a secondary one. Wright and Douglas showed that the phagocytosis of pathogenic bacteria demands a humoral as well as a cellular element; some property of the blood is called into play to act upon the bacterium before effective phagocytosis can occur—the " opsonic " phenomenon. It is possible that this action is required as a countermove to a defence against phagocytosis evolved by the microbe. There seems, in fact, to be an inverse ratio between the virulence of a bacterium and its susceptibility to phagocytosis.

But the matter is not as simple as this, for there are harmless psychrophil bacteria which demand the opsonic action of serum before they can be taken up by leucocytes, though in others this is not the case. Phagocytosis by leucocytes is not equally important in defence against all pathogenic bacteria, it is pre-eminent against the pyogenic cocci, but relatively subsidiary in the case of bacilli of the typhoid-colon group. It may be said that the degree of circulatory polynuclear leucocytosis seen in an infection is a rough index of the importance of this means of defence against the infecting agent, and I have already pointed out, in discussing inflammation, how great a value attaches to the vascular system as a means of concentrating the wandering mesoblast at the point of bacterial attack.

But we must not limit our view of phagocytosis to the behaviour of the leucocytes. Even in his earlier writings Metchnikoff distinguished between the "microphages," as he called the leucocytes, and the "macrophages"—larger cells wandering or sessile, which we now refer mainly to the histiocytes and reticulo-endothelial system, partly to the lymphatic and vascular endothelia. The phagocytic activity of the macrophages for long attracted less remark than that of the more easily observed microphages, but in recent years renewed attention has been paid to the tissue cells. The removal of bacteria circulating in the blood—for example, after an intravenous injection and presumably also in naturally occurring septicæmias—seems largely owing to phagocytosis by macrophages, especially on the part of the reticulo-endothelial system. Durham long ago showed that, when bacteria are introduced into the peritoneal cavity, the macrophages of that sac were at work before there had been time for the microphages to assemble, and that when the work of the latter had been accomplished the drama was closed by the swallowing up by the macrophages of the microphages themselves with their load of bacteria.

Hence, just as we found inflammation and repair mainly carried out by cells of mesenchymal descent, so too we find them largely instrumental in the defence against microbic invasion.

### HUMORAL DEFENCE.

But the higher animals have evolved other means of protecting themselves without the direct intervention of their cells. It has long been known that when an animal has suffered from a given infection, or when it has been immunised against the corresponding microbe, its serum is wont to exhibit certain new properties antagonistic to the microbe in question. These properties may be of more than one kind, and we are in the habit of personifying them as new substances present in the blood under the name of antibodies. Of these hypothetical antibodies—lysins, agglutinins, and so forth—we know almost nothing beyond their observed effects upon the microbe. We do not even know whether the effects in question are due to separate specific antibodies, or whether they are diverse effects of one single substance viewed from different angles. Until their true nature is revealed in the light of modern physical chemistry, and especially of colloidal chemistry, it is scarcely possible to speculate as to how these properties of the serum have arisen, though there is one tempting line of thought. Such antagonistic properties are seen in the blood not only against bacteria themselves, but against their soluble toxins, and against unformed proteins in general. An invading microbe is, indeed, a protein foreign to the body. Now we know that alien proteins are not tolerated by the body; when taken in as food, they are split up in the digestive tract, and, after absorption, built up again into the normal body proteins. If they are introduced artificially by any other route we know that they are soon got rid of, presumably by some process of parenteral digestion. Proteolytic ferments are of almost universal distribution in the body. When foreign proteins are repeatedly introduced the mechanism for antagonising them appears to be stimulated to increased activity.

It would seem possible that the specific antibodies which arise as the result of microbic infection are a specialised form of this more general property and have been evolved from it, but how we cannot well conjecture in the absence of exact knowledge of the nature of antibodies in general. It is, however, interesting to note that some antibodies at least are held by many to be a product of the reticulo-endothelial system, bringing us back to the mesenchyme as the organ of this form of bodily defence also.

Time fails me to speak any more of humoral defence, even if I had the knowledge to do so. I must be content to have put before you in this lecture many old facts in what I trust may have been to some of you a new light. The bewildering multiplicity of facts which confronts the student of pathology is more readily understood in the light of some general principle. It would be misleading to speak of the evolution of disease, which is a state of disharmony with environment, but if we view the signs and symptoms of disease as manifestations of the efforts of the body to bring itself back once more to perfect adaptation, we can very reasonably regard the varied processes called into play as having been evolved from simpler beginnings. Our admiration of the powers of Nature may well be increased by realising how deftly, in the face of new dangers, she has turned some of the primitive faculties of the cell into means of preserving the body intact.

The vocabulary of every language provides eloquent expression to the fundamental influence of vision in our intellectual life. Its symbolism is predominantly visual—insight, foresight, and the rest. In man's ancestors the increasing reliance upon visual guidance by mammals with plastic undifferentiated—i.e., adaptable hands, made possible the emergence of those progressively expanding powers of discrimination that eventually led to the emergence of the distinctive powers of intelligence. The eyes guided the hands to learn an increasing number of acts of skill. This incidentally cultivated the power of tactile discrimination and correlation between touch and vision. The increasing powers of regulating complex movements eventually conferred upon the cerebral cortex the ability to extend the range and precision of the conjugate movements of the eyes. This created the conditions that are essential before a true macula lutea can develop in a mammalian eye. In addition, it made possible the attainment of stereoscopic powers. I need not repeat that argument again, but I refer to it to call attention to newly realised factors that play a part in the process.

### ITS PART IN POSTURE AND BEHAVIOUR.

The researches of Sir Charles Sherrington and his collaborators, especially Prof. Magnus, of Utrecht, have been responsible for calling attention to other ways in which the eyes come to play a part in the control of posture and behaviour. With the increasing reliance of vision the eyes acquire an influence in the regulation of posture (and the automatically-controlled muscular tone that is an essential part of the maintenance of posture) that is lacking in other mammals. The other posture-regulating mechanisms —labyrinthine, cervical, and cutaneous—are controlled by the brain-stem. The ocular regulation of posture, though automatic, involves the cerebral cortex. It thus becomes more intimately associated with the function of acquiring muscular skill. The eventual attainment of the erect attitude by man is one of the expressions of this enhancement of the influence of vision and the increased part it plays in the regulation of posture and muscular activity in general.

---

# SOME REMARKS ON OSTEOMALACIA,

## WITH SPECIAL REFERENCE TO A RECENT CASE.

BY F. S. FOWWEATHER, M.D. LIVERP., M.Sc., F.I.C., D.P.H.,

LECTURER IN CHEMICAL PATHOLOGY UNIVERSITY OF LEEDS; CHEMICAL PATHOLOGIST, LEEDS GENERAL INFIRMARY.

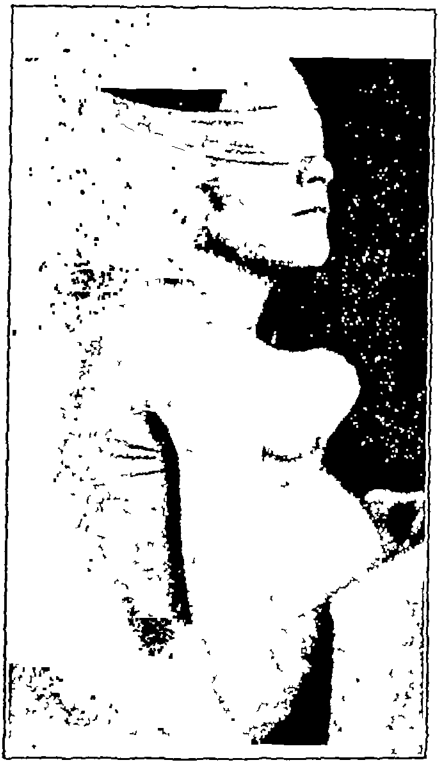
THE case about to be described was admitted to the Leeds General Infirmary in September, 1925. A somewhat full chemical investigation was made and the results obtained appear to be of sufficient interest and importance to be worthy of record.

The patient was a tailoress aged 27. On admission the limbs were thin and wasted, the abdomen very protuberant, and there was marked scoliosis. The most remarkable feature, however, was the extreme distortion of the sternum, which projected forward at an acute angle. These features are illustrated in the accompanying photograph. In addition the terminal phalanx of the right thumb was bent backwards.

She was quite well until 1919, when she complained of backache and some difficulty in walking. She was advised to rest in bed for three months, and at the end of this period she found that she was shorter in height and had lost weight. Difficulty in walking persisted for 12 months. A holiday of two months' duration was followed by considerable improvement, and she resumed work for nine months, but had to discontinue owing to "rheumatism." This occurred in winter, and she has been unable to work in winter ever since. During the past year she has had two attacks of bronchitis, each of about three weeks' duration. For some time before admission she had had attacks of fainting with marked dyspnœa. These attacks came on at irregular intervals and, in view of the subsequent findings, were probably manifestations of acidosis. There was no association of pregnancy with the condition, the patient being unmarried and a virgin.

The X ray report by Mr. H. B. Scargill was as follows:—

"The pelvis shows marked flattening and rarefaction of bone; the neck of each femur has lost its angle (now almost a right angle). Terminal phalanx of right thumb shows deformity. Chest: Nothing reliable can be made out. I do not think there is any doubt about the diagnosis of osteomalacia."



The chemical findings in this case are of considerable interest. They are as follows:—

*Blood.*

| | |
|---|---|
| Sodium .. .. .. .. | 298 mg. per 100 c.cm. serum. |
| Potassium .. .. .. .. | 26·5 „ „ „ |
| Calcium .. .. .. .. | 9·8 „ „ plasma. |
| Magnesium .. .. .. .. | 2·27 „ „ „ |
| Chlorides (as NaCl) .. .. | 556·0 „ „ „ |
| Inorganic phosphorus .. | 3·2 „ „ „ |
| *Non-protein nitrogen* .. | *39·2 „ „ whole blood.* |
| Sugar .. .. .. .. .. | 0·05 per cent. of whole blood. |
| $CO_2$—combining power .. | 42·0 c.cm. $CO_2$ bound as bicarbonate by 100 c.cm. plasma. |

*Urine.*

| | |
|---|---|
| Volume of 24 hours output | 1250 c.cm. |
| Specific gravity .. .. .. | 1012 |
| Titration acidity.. .. .. | 10·92 c.cm. N/10 NaOH per 100 c.cm. |
| Ammonia-nitrogen .. .. | 64·7 mg. per 100 c.cm. |
| Total nitrogen .. .. .. | 670·0 „ „ |
| Ammonia coefficient .. .. | 9·7 per cent. |
| Chlorides (as NaCl) . .. | 5·0 g. per day. |
| Inorganic phosphorus (as $P_2O_5$) .. .. .. .. | 0·86 „ |
| Sodium (as $Na_2O$) .. .. | 2·91 „ |
| Calcium (as CaO) .. .. | 0·29 „ |

*Acetone was present, but was not estimated.*

### *Starvation Acidosis.*

The outstanding features of these results are the low $CO_2$-combining power of the blood together with a lowered sodium and chloride value, with an increased ammonia coefficient and acetone in the urine. There is, therefore, a moderate degree of acidosis. Other interesting features are:—

1. The blood calcium is normal, while the urine calcium approaches the upper limit of normal calcium urinary excretion. Balance experiments by Freund and Lockwood[1] have shown that a definite loss of calcium from the body

*occurs in osteomalacia. A similar loss has been shown to occur in rickets.*

2. The inorganic phosphorus of the blood also lies within normal limits. There is thus no phosphate retention. The excretion of phosphorus in the urine is much below the average.

3. Excretion of many products—e.g., phosphorus, chloride, and nitrogen—is below the average, while the blood concentration of the same substances is normal or reduced. Since the amount of these substances excreted is mainly dependent on the amount absorbed the figures suggest that absorption is not taking place to a normal extent.

4. *The blood-sugar is at an unusually low level.*

The acidosis cannot be due to failure to excrete carbonic acid, though the shape of the patient's chest might suggest inefficient action of the lungs from mechanical causes, for in such cases a marked diminution of the plasma bicarbonate would not be found. Nor is it due to retention of phosphoric acid. It must clearly be due to a ketosis, which, however, is not diabetic in origin. It very closely resembles the ketosis which results from starvation, due to the low level of carbohydrate metabolism which occurs in this condition. The figures quoted may be compared with those obtained by Gamble, Ross, and Tisdall[2] in their study of the metabolism of fixed base during *fasting. For example, on the sixth day of* fasting they obtained the following figures:—

| | |
|---|---|
| Sodium .. .. .. .. | 303 mg. per 100 c.cm. |
| $CO_2$-combining power .. | 45·7 c.cm. per 100 c.cm. plasma |
| Chlorides .. .. .. | 562 mg. per 100 c.cm. |

which are almost identical with those obtained in the present case, or in general terms, there were slight changes in plasma bases with definite depletion of the plasma bicarbonate, the latter being compensated to a slight extent by a diminution of chloride content resulting from a shift of chloride from plasma to corpuscles. They found a considerable excretion of bases in the urine apparently derived from the wasting tissues, except in the case of calcium. In the case of this element the amount excreted during fasting was enormously more than could possibly be derived from destroyed protoplasm, and it must be concluded therefore that calcium was being withdrawn from the bones of the body. Goto[3] has also shown that loss of calcium carbonate from the bones occurs in the experimental acidosis induced by *administration of* mineral acids.

The occurrence of a starvation acidosis such as appears to be present in our case might therefore, if of more than relatively short duration, account for the *osteoporosis, which is the chief clinical feature of* osteomalacia. That osteoporosis occurs to a greater extent in osteomalacia than in other types of ketosis may possibly be associated with the degree of chronicity which *obtains in these cases.*

### *Similarities between Osteomalacia and Rickets.*

Both Sauer[4] and Alwens[5] have put forward the view that chronic under-nutrition is the primary cause of osteomalacia. Pritchard,[6] in a paper dealing with rickets, while noting that acidosis is the essential cause of the bone changes in this disease, put *forward* the belief that all chronic conditions of malnutrition of whatever kind finally terminate in an acidosis, and that all claims on alkaline bases arising in connexion with the neutralisation of this acidosis must be satisfied before those of developing bone are *attended* to.

There is thus a common cause of rickets and osteomalacia—namely, an acidosis resulting from chronic malnutrition—and the differences between the bony changes in the two diseases are due to the fact that in rickets the acidosis is present during the period of bone formation, while in osteomalacia it operates after bone formation is completed.

V. G. and R. H. A. *Plimmer*[7] have shown that an increase in osteomalacia (which they term "hunger osteomalacia") occurred in Austria and Germany towards the end of 1918, under the same conditions that produced *an increase in rickets in children.* They state that no clear connexion had been traced between the osteomalacia of pregnancy and hunger osteomalacia. This connexion has been supplied by Losee and Van Slyke,[8] who have shown that during normal pregnancy a decrease in the alkali reserve of the blood occurs. It is easy to imagine how, in a woman whose nutrition in the absence of pregnancy is at a level bordering upon the *minimum necessary to prevent* acidosis, the further tendency to acidosis which is part of the pregnant condition is a potent factor in determining the onset of osteomalacia. In other words, pregnancy is a potent *factor* in *determining* the onset of osteomalacia in the under-nourished.

Plimmer and Plimmer add another point of similarity between rickets and osteomalacia—namely, that in the 1918 *cases of osteomalacia in adults* the symptoms were at their worst in winter and spring and less severe in summer. This seasonal variation in symptoms is seen in the present case.

### *Chronic Under-nutrition and Acidosis.*

There remains the question as to how a starvation acidosis results from chronic under-nutrition. This may occur either: (1) directly, the diet being of itself insufficient to maintain carbohydrate metabolism at a sufficiently high level; or (2) indirectly, the chronic *under-nutrition* resulting from a qualitative rather than a quantitative diet defect which in its turn causes failure on the part of the organism to absorb and utilise the carbohydrate supplied in sufficient degree for its requirements.

*The second of these appears to be the more probable,* for diets found to give rise to malnutrition are rarely deficient in carbohydrate. The diets involved in the war-time cases of osteomalacia referred to were poor in fat, meat, and fresh vegetables. Unbalanced and deficient diets, aided perhaps by *other unhygienic* conditions, undoubtedly lead to lowered vitality and (possibly by inducing intestinal catarrh, intestinal toxæmia, &c.) to defective absorptive powers. Such defect in absorption is clearly shown by the figures quoted in the present case, and is the immediate cause of the starvation acidosis.

Plimmer and Plimmer believed *the essential cause* of hunger osteomalacia to be a diet deficient in A-vitamin. I consider the cause of osteomalacia, whether of the "hunger" or "pregnancy" type, to be the same as that of rickets, though *I do not* propose to enter the controversy as to how far the latter disease is purely an avitaminosis. In this connexion the work of Cramer[9] is of considerable importance. He holds that the action of vitamins is essentially on the digestive tract, the effect of lack of A-vitamin leading to atrophy of the intestinal mucosa and reduction in blood platelets, while lack of B causes atrophy of the lymphoid elements. Hence all the effects of vitamin deficiency are explainable on the basis of a secondary *deficiency* in absorption (which has been shown to occur in the present case) or to increased local vulnerability to bacterial infection.

It follows that the treatment of osteomalacia must be the same as that of rickets. The healing of bone lesions in adults is *more difficult than* in children, but it is claimed that correction of dietetic and hygienic deficiencies cured the European war-time cases of osteomalacia.

My warmest thanks are offered to Dr. T. Wardrop *Griffith, who was in charge of the* case described, for permission to make this investigation, and for access to the notes.

# TUBERCULOSIS OF THE LARYNX:

## TREATMENT WITH THE GALVANO-CAUTERY: INDICATIONS; RESULTS; TECHNIQUE.*

By Sir StCLAIR THOMSON, M.D. Lond.,
PRESIDENT OF THE ROYAL SOCIETY OF MEDICINE; EMERITUS PROFESSOR OF LARYNGOLOGY IN KING'S COLLEGE HOSPITAL; LARYNGOLOGIST TO KING EDWARD VII. SANATORIUM, MIDHURST.

Perhaps the following contribution can be better followed if I at once state the three chief conclusions I have arrived at. They are as follows: (1) as a local help the galvano-cautery is the most valuable remedy we possess at present; (2) the cases in which it is suitable are relatively few; (3) but these cases, well selected, yield a cure in a large proportion of cases.

*Selection.*—No case is ever submitted to the galvano-cautery treatment until sufficient time has elapsed to note the improvement which occurs in nearly every instance from sanatorium treatment alone. A strict silence treatment has also preceded it in all cases where the tubercle is deposited around the margin of the glottis—i.e., the vocal cords, interarytenoid and arytenoid regions (intrinsic type). If situated elsewhere in the larynx—epiglottis, ventricular bands, aryepiglottic folds (extrinsic type)—a preceding period on whispers may be sufficient.

*Preceded by Voice Rest.*—The cautery treatment is employed when the spontaneous healing in the larynx (under silence or whispers), after having made some progress, appears to be stationary or only improving slowly. It is also used in promising cases where the patient is anxious to resume full voice use, so as to gain his livelihood or return to social life, as quickly as possible.

### *Indications and Contra-indications.*

*Local Indications.*—As regards local distribution and type, the case is more promising when the disease is situated on the vocal cords, the vocal processes and the interarytenoid region (the most common sites), and is in a quiescent and not advancing condition. (Figs. 3 to 7.) It is also indicated when the tuberculous deposit is limited to a ventricular band, or aryepiglottic fold (not common areas for solitary lesions), and is of an indolent type. It may be employed when the epiglottis is invaded, provided it be of the chronic or lupoid form. (Figs. 1 and 2.)

*Local Contra-indications.*—It is contra-indicated in the acute, turban-shaped epiglottis, particularly during the evolutionary period, when the surface is intact and the whole cartilage is tense, rigid, distended, purplish-red, and causing acute pain. If this breaks down and subsides into the lupoid, and generally painless type, the cautery may then be called for.

It is dangerous to employ it if the arytenoids are acutely invaded, with massive deposit, or showing pseudo-œdema; or if there is impaired mobility of the cord or pain, as this indicates perichondritis or even trouble going more deeply to the crico-arytenoid joint. I think such cases are only aggravated by the cautery. Pain and dysphagia are generally contra-indications. Although galvano-puncture of the acute epiglottis or arytenoid is sometimes employed, and successfully, to assuage the pain of dysphagia, I have had little experience of it with this object. Such cases do not often come my way.

*General Indications.*—But, alongside of a study of the local conditions, it is always necessary and equally important to consider the patient's whole case as regards lung condition, tubercle bacilli, temperature, resistance, type of disease, and mentality. This, of course, is best done in a well-ordered sanatorium. I have never initiated the cautery treatment until a patient has been at least three months under observation. The method need not be considered if there is unstable temperature, quick pulse, failing weight, or feeble resistance.

It is useless to submit a patient to the strain of this treatment if, in spite of sanatorium care, he is steadily going down-hill. If he has only a year or two to live it is not kind to martyrise him with silence, cocaine, and a certain amount of strain, when his last days might be made more happy by allowing him to go on using his hoarse voice freely.

### *Parallelism of Pulmonary and Laryngeal Disease.*

It is well to remember that laryngeal and pulmonary progress do not always proceed along parallel lines, although they generally do. Disease in the chest may be stationary or advancing while the larynx is improving; or may be improving or arrested while the larynx shows no tendency to heal. On the other hand, the contrary never occurs—i.e., if the disease is unhealed in the larynx the tubercle in the lungs is likely to recur or extend; if it is spreading in the larynx then it will become active in the lungs. A patient with arrested disease in the lungs cannot safely return to daily life if he still has a laryngeal lesion. If his laryngeal tuberculosis is healed he may carry on for many years with tubercle bacilli in his sputum or chronic lung trouble, or his chest may get well.

### *Incidence of Laryngeal Disease.*

The clinical material at my disposal is well displayed in Table I.

Table I.—*Incidence of Laryngeal Disease in Pulmonary Tuberculosis in a Sanatorium.*

| Period. | Total cases. | With laryngeal disease. |
|---|---|---|
| 10 years (1911–21) | 2541 | 477 (18·77 %) |
| 4 years (1921–25) | 1001 | 143 (14·29 %) |
| Total 14 years (1911–25) | 3542 | 620 (17·50 %) |

It will be seen that in the type of case we get in a sanatorium such as Midhurst—i.e., relatively early cases—the larynx is diseased in about 17·50 per cent. of all cases. This and the two following tables are interesting—first, because two periods have been compiled from case-cards by two independent observers; and, second, because, while showing a certain similarity in the two groups—of a former ten-years and a later four-years period—yet they suggest a diminishing frequency of laryngeal disease. This may be because we are now getting the cases earlier in a sanatorium, or because, as I have conjectured in a previous research, laryngeal tuberculosis is diminishing in frequency, both actually and relatively.[1]

Table II.—*Laryngeal Tuberculosis: Proportion of Cases Selected as Suitable for Cautery Treatment.*

| Period. | Cases with laryngeal disease. | Cases cauterised. |
|---|---|---|
| 10 years (1911–21) | 477 | 74 (15·5 %) |
| 4 years (1921–25) | 143 | 29 (20·28 %) |
| Total 14 years (1911–25) | 620 | 103 (16·61 %) |

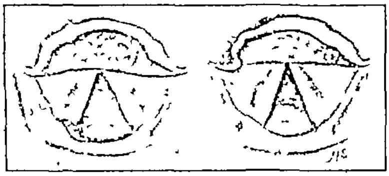
During 14 years I saw 620 cases of laryngeal disease. Of these cases there were 103 I considered suitable for cautery treatment, a proportion of 16·61 per cent. of all cases. (Let me recall that, as many cases are cured simply by silence or whisper, the number available in which the galvano-cautery treatment need be considered is proportionately restricted.) Table II. shows that in the first ten years nearly 15 per cent. were submitted to the cautery, whereas *in the last four years this proportion has* risen to 20 per cent. This again may suggest that we are getting earlier cases, or more suitable cases, or that increased knowledge has encouraged us to employ the treatment more frequently.

---

* Read before the Tuberculosis Society at Cambridge on March 26th, 1926.

[1] StClair Thomson: Tuberculosis of the Larynx, Medical Research Council, H.M. Stationery Office, 1924.

FIG. 1. FIG. 2.



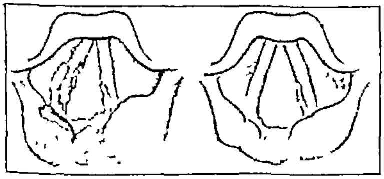
No voice change Indolent type. Cured by whispers and cautery.

FIG. 1.—Male, aged 26. T.B.+. Group 3 Right lung, two apices; left lung, one apex. Deposit above right vocal process; deposit in right aryepiglottic fold, with two superficial ulcers. Ulcerating deposit on petiolus of epiglottis, deposit in right half of epiglottis.

FIG 2—Same case as Fig. 1 after whispers and three cautery treatments. Inspected nine years afterwards, larynx remains *healed, as in this picture, which shows stellate scar on petiolus* and a scarred and shrunken right half of epiglottis.

*Number and Frequency of Treatments.*—In the patients of the first decade, with 46 cured cases, there were *ten who only required one treatment*, nine who required two, and 11 who required three. The remainder required four, five, six, and seven treatments. The cases averaged 3·2 applications. Careful records have been kept which enable me to say that a case may require anything from one to six treatments, and that a month is the average suitable interval between *each application. There was only one case*, out of 46, which required more than seven treatments.

FIG. 3. FIG. 4.



Extensive disease. *Fair general condition.* Cure under silence, whispers, and (to expedite healing) two cautery treatments.

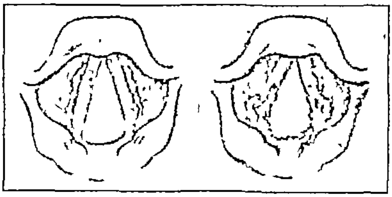
FIG 3.—Male, aged 31. T.B.+. Group 2. Right lung, two apices; left lung, one apex. Right arytenoid is infiltrated and left shows pseudo-œdema, but neither is breaking down. Infiltration and ulceration of all right cord, edge of right ventricular band, interarytenoid region and posterior half of left cord. Admitted June, 1913. Afebrile except for two weeks. On discharge in August, 1914, there were no T.B., the disease in the lungs was arrested and the larynx had slowly but steadily improved.

FIG. 4—Same case as Fig. 3 one and a half years later—i.e., in December, 1914 The right arytenoid, the interarytenoid regions, and the right cord are now healed. There is some thickening of the left arytenoid and aryepiglottic fold, but no ulceration. The left cord is healed except for a boat-shaped ulcer over the vocal process. It was only to expedite the healing of the little disease remaining that two cautery treatments were given in November and December, 1914. In March, 1915, the larynx was quite healed. It remained so when inspected in February, 1923, ten years after entering Midhurst, and eight years after the last galvano-cautery treatment.

### *Results.*

The experience of the first ten years showed a cure in 62 per cent. of cases. (Table III.) In the last four years this has risen to nearly 60 per cent., either because the cases are better selected, or are of an earlier and more favourable type. In my first ten years of sanatorium work we secured by silence, whispers, or the galvano-cautery a lasting cure of 119 out of 477 cases of laryngeal tuberculosis, or 25 per cent.

FIG. 5. FIG. 6.



Cured with silence and cautery (three treatments).

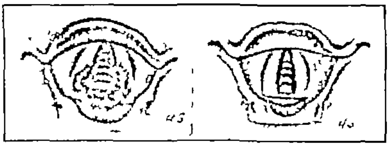
FIG. 5—Male, aged 31. T.B.+. Group 2. Right lung, one apex. Febrile for first 16 weeks. Admitted February, 1915, and discharged September, 1915. This drawing was made in June, 1915, and shows catarrhal and abraded cords, with deposit in both ventricular bands and ulceration along their margins. Silence not carried out as strictly as required. No progress as regards lung or general condition.

FIG 6—Same case as Fig. 5, but five months later—Dec. 2nd, 1915. Readmitted with the same lesion in right lung, and now with two apices in left Disease in larynx increased, the posterior half of both cords being deeply ulcerated. Treated with strict silence and the galvano-cautery (three applications), left sanatorium cured on June 13th, 1916, with T.B.—. Afterwards served with army in France and remains well seven and a half years afterwards.

### *Technique.*

The treatment is carried out by the indirect method of laryngoscopy. It is a great pity that the younger laryngologists of to-day neglect to train themselves in this procedure, as they are in such haste to carry *out any intralaryngeal surgery by the* easier, quicker, but much more painful performance of the direct or Killian method. The latter is not *only unnecessary*, but quite unsuitable for a tuberculous patient.

FIG. 7. FIG. 8.



Stenosis after much galvano-cautery treatment requiring tracheotomy.

FIG. 7.—Female. T.B.+. Group 3. Picture in 1911. *Ulcerating* deposit of interarytenoid region and posterior half of both cords Had 14 treatments with the galvano-cautery. See description of case.

FIG. 8.—The same case as in Fig. 7. Picture in 1923. Larynx quite healed, but with scarring in the interarytenoid region and the posterior commissure. This requires the wearing of a tracheotomy tube, but does not prevent her from managing a post office. No T.B. Lungs quite healed.

*Anæsthesia.*—Complete local anæsthesia of the larynx and good control of the laryngeal reflexes are necessary. The pharynx is first well sprayed with a 2½ per cent. solution of cocaine. A few minutes are allowed for this to act, and then a 10 per cent. solution (to which a few drops of adrenalin have been added) is dropped from a laryngeal syringe along the margins of the epiglottis and on to each arytenoid eminence (Fig. 9). After a lapse of three or four minutes ten drops of the same solution are trickled down over each ventricular band, and this is followed by squirting 10 to 20 drops into the larynx, at the moment that the patient utters a prolonged "E." (Of course, this is all done under the control of the laryngeal mirror, the patient holding his own tongue so as to leave the laryngologist with his two hands free.)

TABLE III.—*Laryngeal Tuberculosis treated with Cautery: Proportion of Cases Cured.*

| Period. | Larynx cauterised. | Larynx cured. |
|---|---|---|
| 10 years (1911–21) | 74 | 46 (62·1 %) |
| 4 years (1921–25) | 29 | 20 (68·97 %) |
| Total 14 years (1911–25) | 103 | 66 (64·08 %) |

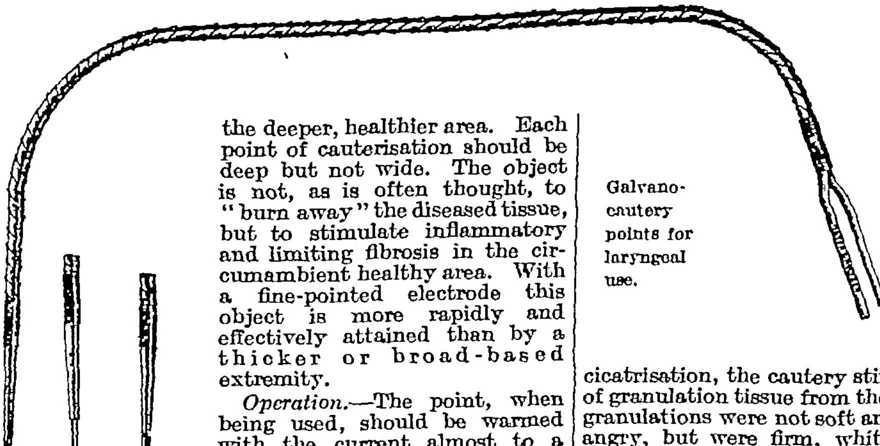
In this way the margins and cavity of the larynx are rendered so insensitive that after another four or five minutes it is possible to introduce a laryngeal cotton-carrier into the larynx and quietly apply a 10 per cent. solution (or, if need be, a 20 per cent. solution) to the exact spots to be cauterised.

This method of securing complete anæsthesia generally requires, from start to finish, about 15 to 20 minutes. Attempts to shorten the induction of anæsthesia are apt to spoil the whole proceeding. If the application is started before the larynx is well prepared, the sitting may prove a fiasco. Still, some patients will continue to make gagging efforts until told authoritatively that insensitiveness is now complete and that they will feel nothing. Confidence and suggestion help in the result.

In nervous and apprehensive patients a dose of 20 gr. of bromide may be given an hour beforehand, but a hypodermic of morphia (gr. ¼) and atropine (gr. 1/200) is more effective. As a rule, neither of these sedatives is required at Midhurst.

*Cautery Instrumentation.*—The cautery extremity is always of the one type, a fairly sharp-pointed platinum. (Fig. 10.) The object is to penetrate swiftly through the margin of the diseased area so as speedily to reach the deeper, healthier area. Each point of cauterisation should be deep but not wide. The object is not, as is often thought, to "burn away" the diseased tissue, but to stimulate inflammatory and limiting fibrosis in the circumambient healthy area. With a fine-pointed electrode this object is more rapidly and effectively attained than by a thicker or broad-based extremity.

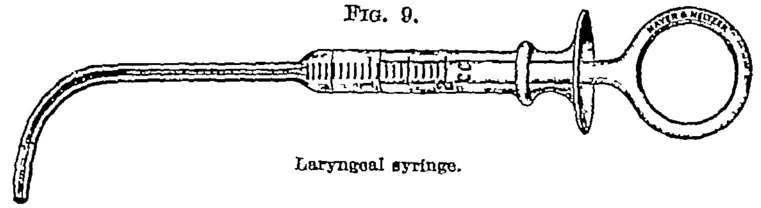
FIG. 10.



Galvano-cautery points for laryngeal use.

*Operation.*—The point, when being used, should be warmed with the current almost to a white heat. It is not sufficient to have it at the "cherry red" degree of heat we are accustomed to employ when making the more superficial cauterisation in the nose and pharynx. For the deep galvano-caustic puncture required in laryngeal tuberculosis, the platinum point at an almost white heat will penetrate more quickly and effectively, and can be as rapidly withdrawn, without fear of its adhering to the tissues. At a red heat the penetration is slower and more *painful*; more diffuse heating and consequent reaction is produced and, on starting to withdraw a point *at red heat, it* is often found to be adherent to the charred tissues, so that, in detaching it, part of the eschar comes away and bleeding may be caused. The current is not switched on until the point is just touching the spot to be heated. Then contact is made and the point is firmly pressed through the margin of an ulcer or deposit until it is felt that its deeper progress is being arrested—as occurs when healthy tissue is reached. Here it is held for a few seconds (five to ten) until it is seen or felt that a free, deep, black shaft has been burned. The electrode is then withdrawn from the tissues into the lumen of the larynx, before the electric current is switched off by releasing the contact on the cautery handle. Two to six such punctures are made at one sitting. In the case of one vocal cord, for instance, three such deep applications may be required, one towards each end and one through the centre. It is better to make one or two punctures at the right points and thoroughly, than three or four incomplete or partially successful applications. The number at each sitting must be determined by the operator's skill and the patient's reaction.

FIG. 9.



Laryngeal syringe.

*Immediate Result.*—There should be no marked ill-effects from this treatment. A short rest, and a cup of coffee or tea, to counteract any depression from the cocaine, is all that should be necessary. A dose of bromide or aspirin might be required to calm agitation, or a hypodermic of morphia.

Silence should be enforced for three to five days and then whispers until the next sitting or until the eschar falls and the burn heals. No topical measures do anything but irritate a larynx requiring rest. In the majority of cases there were no ill-effects. When I make these applications in private practice the patient is able to come up to London and return to the country in the same day.

A general anæsthetic is, of course, quite uncalled for in this treatment.

### *Occasional Sequelæ of Galvano-cautery Treatment.*

(*a*) *Redundant Granulations.*—In a few cases, including some which ended in satisfactory cicatrisation, the cautery stimulated a free outgrowth of granulation tissue from the diseased surface. These granulations were not soft and gelatinous, nor red and angry, but were firm, white, and rather avascular, looking somewhat like warts as seen on the skin. They were chiefly in my earlier cases, and were, I think, caused by inserting the cautery point in the centre of the ulcer instead of along the margin. In the diseased area the cautery throws up these granulations; along the border line it only stimulates fibrosis. The production of these indolent and firm granulomata had no bad effect further than retarding the progress of the case. Some time, even months, had to elapse before they subsided.

(*b*) *Stenosis.*—In only two cases could troublesome stenosis be attributed to the use of the galvanocautery. The first was a long and inveterate case in a young woman of 29, who was admitted in 1911 with tubercle bacilli in sputum, symptoms in two lobes of the right lung, and ulcerating deposits in the interarytenoid region and the posterior thirds of both vocal cords. (Fig 7.) She had a long course of tuberculin without benefit. In 1912 the galvanocautery was started, but as the circumstances did not permit of continued treatment the applications were spread over six years, during which time she had 14 sittings The last was in 1917 when the lung was well fibrosed, bacilli had disappeared from her sputum, the voice was satisfactory, and the larynx well cicatrised. She had a good glottic airway and returned to her occupation in the post office; three years later the patient was shown before the Royal Society of Medicine [1] But towards the end of 1921 she began to complain of dyspnœa, and it was seen that this was due to contraction of the scar-tissue in the interarytenoid region (Fig. 8.) She declined a tracheotomy until Oct. 12th, 1922, by which time she could hardly walk a mile, dare not climb the stairs of an omnibus, and had commencing stridor. A low tracheotomy was carried out under local anæsthesia. She has since gained 7 lb. in weight, can now walk five or six miles, talks easily with a speaking-valve in her cannula, and manages a country post office Her lung trouble remains quite arrested. She is now aged 44; it is 13½ years since her last sojourn at Midhurst. This laryngeal stenosis only set in four years after the last application of the galvanocautery. The patient, wearing her tracheotomy tube, was again shown before the Section of Laryngology, Royal Society of Medicine, on May 4th, 1923—seven months after the performance of the tracheotomy.[2] She remains well and active, three years and a half after the introduction of her tracheotomy tube.

In the second case the patient had had tubercle bacilli in the sputum for two years The right side of the larynx was immobile from infiltration of ventricular band and arytenoid, with ulceration of all right cord and posterior half of left Cautery treatment was started in August, 1923 She had in all six applications, the last being in June, 1924. Stenosis required a tracheotomy in October, 1924 She still wears the tube, the larynx is quite healed, there is no sputum, the lungs are arrested, and she is able to carry out her household duties.

SUPERVISION AND COMPENSATION OF SMALL-POX CONTACTS.—On March 10th questions were asked in the House of Commons about the refusal of the Ministry of Health to sanction the payment by a local authority of compensation to certain miners who, owing to the danger of infection from small pox, were restrained by a medical officer of health from following their employment (THE LANCET, March 20th, p. 633). The Assistant Secretary to the Ministry has now sent to sanitary authorities a circular which draws their attention to Circular 350 of Nov 6th, 1922, and Memorandum 71a/Med., and continues as follows: "The Minister finds that in certain cases local authorities, in dealing with outbreaks of small pox, still think it necessary to quarantine in their homes the inmates of dwellings invaded by the disease or to direct such inmates to refrain temporarily from continuing their ordinary employment, with the result that the local authorities are faced with claims for compensation for loss of wages by the persons so dealt with. I am again to draw the attention of the authority to Section 7 of Memorandum 71a/Med., and to state that the Minister is advised that, save in the exceptional cases noted in paragraph (3) of that section, it is not necessary for persons who have been in contact with a case of small pox to abstain from following their usual occupations. I am also to remind the authority that there is no legal authority for the payment of compensation in these circumstances, and it must not be expected that the Minister would be willing to sanction any such payment under the Local Authorities (Expenses) Act, 1887, in a case in which he was advised that the steps taken by the authority were not necessary for the protection of the public health."

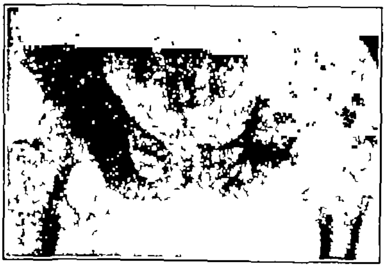
# THE LATE RESULTS OF OPERATION FOR CHRONIC PAINFUL HIP.*

BY C. MAX PAGE, D.S.O., M.S. LOND., F.R.C.S. ENG.,
SENIOR SURGEON TO OUT PATIENTS, ST. THOMAS'S HOSPITAL.

AT first sight the title of this paper may appear somewhat latitudinarian and unscientific. When, however, one considers the limitations and vagueness of our knowledge of the several pathological changes which may cause chronic pain in the hip-joint, one must allow that an indefinite title is in some measure justifiable.

I do not propose, however, to include any consideration of tuberculous infection of the joint, although cases of this nature would come under the category of chronic painful hip. The omission of these conditions is desirable, I think, as the infective factor in them assumes an importance in relation to operation and its results which is not present in other forms of chronic arthritis. For similar reasons and on account of its rarity I shall not discuss syphilitic arthritis.

FIG. 1.



Bony ankylosis of left hip in slightly adducted position, following operation for hypertrophic osteo-arthritis.

For practical purposes this leaves for consideration the late results of cases of chronic arthritis of the hip-joint of a kind which will fall under one of the three following headings—viz.: (1) Primary monarticular osteo-arthritis (hypertrophic and atrophic forms). (2) Chronic arthritis secondary to fracture of the neck of the femur or of the acetabulum. (3) Polyarticular arthritis involving the hip (including rheumatoid arthritis and borderline cases).

Any discussion as to the class of case suited to operation does not come under consideration, and I will therefore proceed to classify the operative procedures which may be employed in these cases and indicate the results which have been recorded in relation to them. I will conclude by giving my own personal experience in a limited group.

Four operative procedures are sufficiently well recognised to merit consideration—viz.: (1) arthrodesis of the hip-joint; (2) excision of the head of the femur; (3) cheilotomy; (4) arthroplasty.

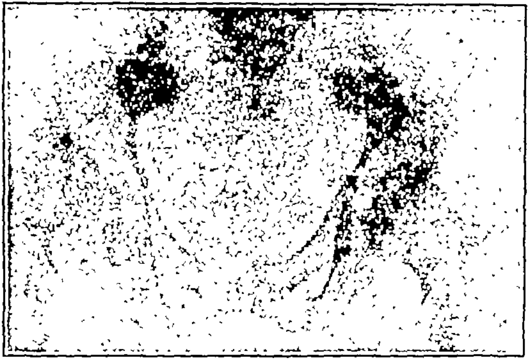
### *The Choice of Operation.*

The choice of operation in this joint is less dependent on the anatomical condition of the joint or ætiology than on the age and general condition of the patient. In the young and middle aged the aim should be not only to remove pain, but to provide a stable joint. This can be most effectually done by producing bony ankylosis at the joint line An *arthrodesis* is most certainly produced by a complete erasion of the joint, followed by fixation in plaster-of-Paris in the position of election for a sufficient time to allow bony union to occur. This procedure was first advocated by *Albee*[1] in 1908. In his early series he merely rawed the upper surface of the femur and corresponding aspect of the acetabulum. Latterly he has adopted a more thorough exposure of the joint, and further ensures bony ankylosis by the insertion of an autogenous bone graft. In the series of cases, the results of which I report later, I have usually dislocated the head of the femur and carried out an erasion of the joint.

---

* Read before the Orthopædic Section of the Royal Society of Medicine on March 2nd, 1926.

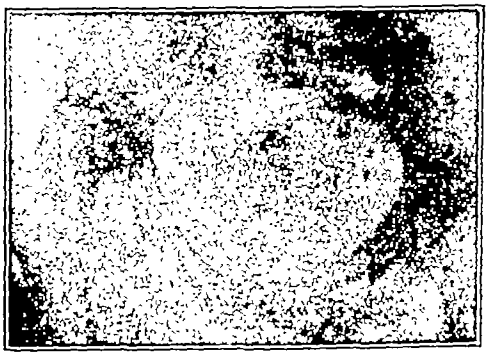
FIG. 2.



Fibrous joint. Right hip following operation for hypertrophic osteo-arthritis.

This operation must be regarded as a severe one, though in my experience it is not associated with much shock. It is the prolonged after-fixation in plaster-of-Paris in the recumbent position which is found most trying by the patient. The functional results of a fixed hip in a satisfactory position are remarkably good in the younger subjects. The most serious disability noticed by the patient is, as a rule, the difficulty he experiences in doing up his boot on the side affected.

FIG. 3.



Fibrous joint. Right hip after operation for partially dislocated head of femur following chronic arthritis.

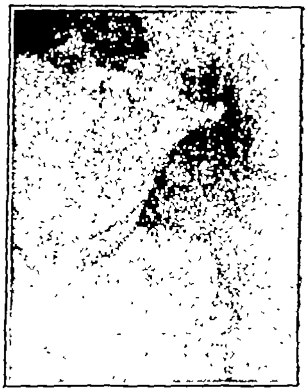
In reviewing the later results, it is noticeable that elderly subjects sometimes develop pain in the lumbar spine and sacro-iliac joints after an arthrodesis of the hip. The fixation of the hip undoubtedly imposes a serious strain on these joints. I have noticed that pain of this character is most prominent in the first year or two after operation and generally diminishes rather than increases later.

In elderly feeble patients an arthrodesis is not usually attempted. A simple *excision of the head of the femur* has been most often favoured. Sir Robert Jones[2] advises the production of a pseudo-arthrosis at the base of the neck of the femur without touching the diseased joint. Both these latter operations relieve pain, but leave a joint of poor stability, and mean that the patient is left dependent on the use of crutches or a walking caliper.

The more conservative procedure of *cheilotomy* (Sampson Handley) is suited to but few cases, and it cannot be expected to give a lasting cure. Platt advocates a partial excision of the head of the femur, leaving sufficient bone to engage the upper rim of the acetabulum. This leaves, in favourable cases, a stable joint with fair mobility.

In my own experience the operation of erasion of the joint has been well tolerated by old patients, and I have merely varied the after-treatment in their cases by making no attempt at rigid fixation in plaster-of-Paris. A painless fibrous ankylosis or pseudo-arthrosis is in this way obtained in a relatively short time; the hip is stable, but there is a tendency to the development of an adduction deformity.

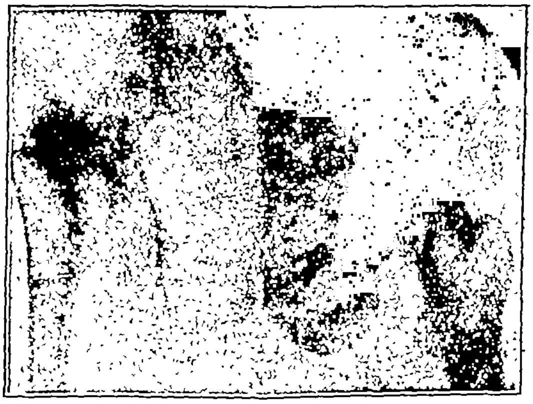
FIG. 4.



Ankylosis of left hip after operation for traumatic arthritis following a fracture of the acetabulum and ilium.

The performance of a formal *arthroplasty* in the case of the hip-joint is a doubtful policy, and is hardly necessary in cases of osteo-arthritis. As stated above, a useful range of movement at the hip is obtained by an erasion or partial excision of the joint followed by suitable after-treatment. Indeed, it is not easy to secure a sound bony ankylosis at the hip-joint, as is made clear by the results seen in Table 1. This experience falls in line with the frequency with which a pseudo-arthrosis is formed after an unimpacted intracapsular fracture of the neck of the femur. This suppression of new bone formation within the joint may be attributed to the exposure of the broken surfaces to the influence of synovial fluid; the same condition prevails after an erasion or excision of the hip for a non-inflammatory condition.

FIG. 5.



Fixation of femur in good working position after operation of excision of the head for a painful ununited fracture of the neck.

### *Factors in the Production of Adduction Deformity.*

In examining the later results (Table 1) of cases of operation on the hip-joint, the tendency to the development of an adduction deformity is striking. This deformity results in serious functional shortening of the limb, from tilting of the pelvis when the erect attitude is assumed. As it is manifestly a complication to be avoided it is worth while to examine the factors which are responsible for its production.

Adduction deformity is a notable feature in any case of destructive disease of the hip-joint. It appears to be due to at least two causes: (1) The proportionately excessive wasting of the gluteal muscles, which lie in intimate relation to the joint; the adductors, which are normally the master group, are at a greater distance from the articulation and do not suffer so severely. (2) The abducting power of the gluteal and tensor fasciæ femoris is reduced by the shortening of the lever (the neck of the femur) through which they act. Both these factors are operative in some degree after the operation under consideration. First, the muscles may be mechanically damaged or the nerve-supply interfered with if the incision is not carefully planned; secondly, any considerable removal of bone from the head of the femur, or unusual deepening of the acetabulum, will shorten the lever through which the muscles act.

The problem of avoiding the secondary development of adduction after operation only arises when a fibrous joint is the result. If firm bony ankylosis is obtained in a good position by means of proper fixation the difficulty does not arise; but it should be remembered that sound bony union is not always obtained, however carefully the operation may be carried out, and that union, apparently firm, if due to fibrous tissue is liable to gradual stretching.

In all cases, therefore, of operations of this nature the two simple mechanical factors above enunciated should receive attention—viz.: (1) preservation of the full function of the gluteus medius and minimus and tensor fasciæ femoris, and (2) the preservation of the neck of the femur at as full length as possible. In practice the adductors may be weakened by section of their tendons, followed by forced abduction of the thigh. To correct the result of shortening of the neck of the femur, Whitman[3] advocates the reimplantation of the bony insertion of the gluteus medius and minimus into the shaft of the femur a couple of inches below the normal position of the great trochanter. I have no experience of this procedure, but it seems to be based on sound lines.

### *Late Results of Operation.*

When one comes to estimate the value of late results of these various operations the view of the patient and that of the surgeon differ somewhat. The former is well satisfied if he loses his pain and is left with a limb whose functional value is not worse than before operation. The surgeon, on the other hand, recognises that the removal of the pain is readily effected and looks rather for an improvement in the functional value of the limb. In either case the true merit of the procedure can only be fairly assessed by a study of the results some years after operation. This particularly applies if operation is undertaken during the active period of the patient's life, when the resulting function of the limb is almost as important as the relief of pain.

The evidence in the literature on the subject is somewhat meagre, only a few authors having published the details of the late results of any considerable number of cases. The outcome of operations aiming at arthrodesis has received the most attention.

Ozarki[4] in 1917 records the results of the arthrodesing operation of the hip in 10 cases of polyarticular arthritis and 16 of the monarticular variety. The same cases were reported on a few years later. In 1920 Spiers,[5] in a careful survey of the late results of all the cases operated on between 1908 and 1920 at Brackett's clinic, sets them out in tabular form as follows:—

| | | | |
|---|---|---|---|
| Operated on .. .. | 34 cases | Youngest .. .. | 22 years. |
| Examined later and reported .. .. | 25 ,, | Oldest .. .. | 61 ,, |
| Average age .. .. | 46 years. | Mortality .. .. | 2 cases. |
| | | Average interval since operation .. | 4½ years. |

*Results of Examination.*

| Union. | Cases. | Position. | Cases. |
|---|---|---|---|
| Union firm .. .. .. | 17 | Adduction present in .. | 18 |
| ,, doubtful .. .. | 3 | Normal .. .. .. | 4 |
| Non-union .. .. .. | 5 | Abduction present in .. | 3 |

He found that in the cases unrelieved by operation arthrodesis had not been secured. Albee,[1] in 1921, reported that he had operated on 128 cases with satisfactory results. Details of these cases in regard to the technique of operation and the late results are not published.

The results of the operation of excision of the head of the femur for this condition have not been reported in any large series. Individual experience appears to vary. Pain is relieved in all cases, but the functional value of the joint is reported on as a whole unfavourably, considerable shortening being the rule and stability uncertain (Fock, Zezas, Müller, and Hoffa).[6,7,8,9] Platt has reported to me that he has carried out a modified excision in some 20 cases. He considers that though pain is thereby relieved surely the average function given by this operation is disappointing.

Turning now to my personal experience, I have operated on 57 cases of chronic arthritis of the hip from 1919 to date. The first of these cases formed the basis of a detailed report which I put forward in a Hunterian lecture read in 1924[10]; the following results are an amplification of those published on that occasion.

The series is made up of the following types: monarticular osteo-arthritis, 48; polyarticular osteo-arthritis, 2; traumatic osteo-arthritis, 7. In the 48 cases operated on for chronic arthritis an erasion of the joint was effected by one of the methods previously described in 47. After-treatment was carried out with a view to obtaining bony ankylosis in 38 cases, and a fibrous joint in 10. Eleven of these cases were operated on in 1925, and therefore are of no value in assessing the late results.

TABLE 1.—Total cases to January, 1926, 57. 46 cases operated on at least a year ago.

| Condition of joint. | Position. | Pain in hip. | Funct. Short. | Funct. Value. |
|---|---|---|---|---|
| Bony ankyl., 26<br>? ankyl., 7<br>Fib. joint, 13 | Normal, 8<br>Adduct., 35<br>Abduct., 3 | Absent, 38<br>Slight, 8 | Aver.<br>1 3 | Good, 28<br>Fair, 13<br>Poor, 5 |

Ankyl. = ankylosis. Fib. = fibrosis.

TABLE 2.—Functional results in regard to age (46 cases).

| Age 20–49. | | | | Age 50–75. | | | |
|---|---|---|---|---|---|---|---|
| Cases. | Good. | Fair. | Poor. | Cases. | Good. | Fair. | Poor. |
| 22 | 18 | 4 | nil. | 24 | 13 | 7 | 4 |

As might be expected the functional results are more often satisfactory in the younger patients.

TABLE 3.—Relation of Fixation to Function (46 cases).

| Condition of joint. | Cases. | Good. | Fair. | Poor. |
|---|---|---|---|---|
| Ankylosis .. .. | 26 | 24 | 2 | — |
| ? ankylosis .. .. | 7 | 4 | 3 | — |
| Fibrous joint .. .. | 13 | 3 | 6 | 4 |

Table 1 gives in outline the late reports of the 46 cases in which operation was carried out between January, 1919, and January, 1925. The average age of these cases was 47·5, the oldest was 73 and the youngest 24. The results tabulated were obtained by clinical and X ray examination made at least a year after operation. The reports on six of these cases are not recent as I have lost touch with the patients. Two cases have died a year or more after operation. The statements in regard to the absence of pain are

+ – Weakly positive.

had so much improved that he was discharged on trial, and continues to do well at his ordinary work.

From the two cases quoted it will be seen that the actual conversion of the colloidal gold reading cannot be said to have a real bearing upon the mental condition. Possibly, however, on the physical side one is more able to give a general opinion that with the disappearance of globulin, the reduction in the number of cells, and the reduction of the "reducing power" of the fluid, one may expect some improvement in health. In support of this, perhaps two cases may be instanced.

CASE 5, admitted in extremely poor health and with faulty habits, showed positive globulin, increased cells, and a reading of 5555555432. Now, 24 months after the termination of malaria, he is in good health, working in the wards and grounds, and is scrupulously tidy and clean in person. His cerebro-spinal fluid shows a negative globulin reaction, marked reduction in cell count, and a reading of 0032110000.

In contrast, Case 27, admitted in somewhat similar condition with readings 5555554300, markedly positive globulin and increased cells, shows a very marked deterioration in his physical state with readings 5555555552, and a positive globulin and larger number of cells.

It is true the latter case has only been treated within the last ten months, but his condition will not respond to any attempted treatment.

In the alteration in readings it has been repeatedly noticed that the change commences at the paretic end of the curve, and this is the more worthy of note, as so frequently the reduction of the first or first and second tubes is held up by the presence of sero-albumin, whilst when a change is found in the reading it is frequently coincident with the disappearance of demonstrable globulin. Apparently, therefore, when the reading is so little altered in the Lange's gold sol, in spite of a negative globulin reaction, the balance between the precipitating action of the globulin and the protective action of the albumin on the gold solution has been disturbed.

We have not found that the induction of a second series of malarial pyrexia has any marked quickening effect on the alterations taking place in the fluid, and are inclined to consider that where a change is evidenced in a reading taken after such a second attack, it is due to the interval which has elapsed since the first malaria; in other words, that the effect on the fluid of the first malaria is still going on. We have administered arsenic in various forms on the conclusion of the pyrexia, mainly in the form of "914," but cannot find any evidence of the "clearing" of the cerebro-spinal fluid thereby. Case 33 has received in all 5 g. intravenously, and he shows as yet no appreciable alteration in the fluid. The number of rigors sustained does not seem to have any effect upon the cerebro-spinal fluid, because Cases 15 and 23 had respectively 10 and 2.

It has been of interest to us to compare the results obtained by the globulin and Lange's tests with those shown by the acetic-anhydride method. At present we are endeavouring to combine the three in reading results, but frequently find that a known general paralytic shows anything but a true paretic curve, negative globulin, diminution in the cell count, and yet gives a positive reaction to the acetic-anhydride test after malarial therapy. Whether this would indicate the presence of a neuro-syphilis we are not in a position to say, as the chemistry of the test seems to be quite unknown. The fact, however, remains that if the case from which the reading was obtained was unknown, the diagnosis from the Lange's test would in all probability be that of neuro-syphilis.

We are again indebted to the medical superintendent for his kind permission to quote hospital material.

# Medical Societies.

## ROYAL SOCIETY OF MEDICINE.

### SECTION OF SURGERY.

A MEETING of this Section was held on Wednesday, June 2nd, Sir LENTHAL CHEATLE, the President, occupying the chair.

Dr. W. E. GYE gave a communication on the

### ORIGIN OF TUMOURS.

He said that the subject belonged to that group in regard to which there were almost as many opinions as there were medical men. To put forward an entirely new view required some courage. But when he first submitted to the profession the ideas which he held at the present time, it was not so much a matter of courage as of bland ignorance of the tenacity with which current views were held by most people, and particularly by pathologists. What could be regarded as the orthodox view of the origin of cancer was what was known as the cellular hypothesis. Candidly, he did not know what that meant, though he had tried to ascertain what it was held to mean by personal inquiry and by reading. Still, it was easy to understand why the so-called cellular hypothesis was held so firmly—even dogmatically—by pathological anatomists all over the world. Apparently, the general meaning of that hypothesis was that the ultimate explanation of the essential features of tumours would be found in some change in the internal growth mechanism of the cell. It was held that this change might be induced by many kinds of things, such as by the action of tar and other chemicals, or by the action of worms, or by an invisible virus in the case of certain fowl sarcomata. Underlying the dogmatism with which such views had been expounded was a radical misuse of the word "cause." Pathological anatomists employed that word in a sense other than that in which it was used in ordinary medicine—i.e., the bacillus of Koch as the cause of tuberculosis. In medical speech one meant by the word "cause" factors invariably present in the disease. Contributory factors were present in all diseases. The problem at the present time was to connect ætiologically a tumour of one species with a tumour of another species. Tumours, though exhibiting microscopical and biological unity, were nevertheless found, when examined by experimental means, to be apparently individual and separate. It was towards a solution of this mystery that he had been bending his energies during the last few years. A strong belief in the cellular hypothesis involved an almost fervent animosity towards the parasitic hypothesis. The evidence which had been served out against the latter was negative evidence, and dogmatic conclusions could not be drawn from negative evidence. With few exceptions, tumours could be propagated only by means of living cells. When the cells were killed, by heat or by mechanical disintegration, by freezing or by thawing, the dead product was no longer effective. Infection of the host cells did not usually occur, but an exception to that rule was found in the case of mouse tumours, in which the connective tissue stroma became involved.

Two points stood out clearly: (1) If the cause of cancer be found, it must fit firmly into existing established knowledge. (2) If the cause be a living thing, the infective process is something different from what we are already acquainted with. If the cause were a microbe it was not unreasonable to expect, by simple inoculation of a pure culture of the microbe, to cause a reproduction of the tumour in another species of animal. Tuberculous tissues taken from man, or dog or monkey, would, when inoculated into a guinea-pig, cause tuberculosis, and in that case isolation of an organism established the organism as the cause of the disease. In the case of cancer, however, the first part of the process—the inoculation of morbid material—was always attended by failure when another species of animal was used, and indeed in the same species when the cells were killed. Therefore, if there was an organism of cancer, it did not act in the simple way that the organism of tuberculosis did. The failure to find any evidence upon which a rational ætiological theory might be built had led, on the one hand, to the wildest speculations, particularly among those who had not acquainted themselves with the large amount of exact knowledge which experimentation had yielded. Among morbid anatomists there was a pessimistic scepticism which was not far removed from obscurantism.

### *The Rous Tumour.*

For three years he had been giving very considerable study to sarcoma of the fowl, which was first described by Peyton Rous, of the Rockefeller Institute. Rous described three tumours of which the one still surviving was a spindle-celled sarcoma, which could be transmitted by filtrates through fairly fine candles, or by dry material, or by cultures made by dropping a fragment of tumour into a medium and then incubating it for seven days, after which the fluid was infective. This tumour deserved very close study, and Dr. Gye proceeded to demonstrate, by means of the epidiascope, some of the important aspects of the work which he and his colleagues had been doing. The tumour was not always filterable; its filterability certainly was not constant. When working at this subject over a long period it was observed from time to time that filtrates prepared, apparently, in exactly the same way were, in one case, excessively infective, while at other times they were barely infective at all. Last summer a tumour with which he had worked for more than two years suddenly lost its filterability.[1] This variation in filterability seemed to dispose of the argument which had been advanced by pathologists all over the world—namely, that this tumour of the fowl was not a true tumour, because it was transmissible by filtrates. Again, if one took filtrates of the tumour, one observed another interesting fact—that the tumour produced by filtrates was proportional to the size of the inoculum. It was only fair to inject the same amount of fluid on each side so as to expose an equal number of cells in both breasts to an equal chance of infection. Therefore 1 c.cm. of the filtrate was inoculated into the right breast, and a mixture consisting of 0·5 c.cm. of the filtrate and 0·5 c.cm. of saline was inoculated into the left. In the left breast the resultant tumour was as 1 to 2 of that in the right breast, as measured by the rule. One could not weigh these tumours because of the invasion of muscle and other tissue, but the fact that the same proportions held in a large series of experiments was most significant. Most of the birds thus treated died before the twenty-eighth day.

In another series of birds filtrates from the tumours were treated with a small quantity of chloroform for two hours and then inoculated in a dose of 1 c.cm. in one breast, 0·5 c.cm. (with 0·5 c.cm. of non-active material) in the other. In a chart shown typical of this series the bird died only on the thirty-fourth day, and the tumours were of slower growth, but the same proportion between the two breasts held good. In another series a large quantity of chloroform was added, reducing the infectivity of the filtrate to nil. Chicken embryo was added, but that did not restore the potency of the inoculum. Murphy, in America, had recently reported that he had been able to restore the infectivity of the Rous filtrates which had been destroyed by chloroform, by the addition of chicken embryo, and by cultures of mouse placenta. Dr. Gye had tested chick embryos more than 150 times without being able to restore lost infectivity by this means.

---

[1] See THE LANCET, May 22nd, 1926, p. 990.

With a severe chloroforming the infectivity was so far reduced that the tumour was formed only very slowly, the bird not dying until the fifty-second day, and with a tumour in only one breast, 0·5 c.cm. not having been infective at all. He had never believed that chloroform killed the *whole* of what he regarded as the virus in a filtrate, but this was really beside the point. The really important thing was that one could restore the infectivity which had been destroyed by the addition of chloroform by adding a culture from another tumour, though this did not apply to all tumours. Another important point was that one could reverse what was a regular rule—the proportion between tumour and dose—by adding a culture from another tumour to the inoculum of chloroformed material into one breast. It seemed quite clear that in the rat sarcoma was something which was common to it and to the Rous sarcoma, and that that which was common to both could be taken from tube to tube.

In conclusion, Dr. Gye said that when he published the preliminary notice of his work last July he naturally felt certain of his facts—otherwise he would not have published them—and he felt fairly confident that the interpretation he placed upon what he found would prove to be correct. Now, after still further work, and an investigation by other means, he felt still more confident.

### *Discussion.*

The President, in the name of the Section, thanked Dr. Gye for his masterly and logical résumé of his work. He referred to the possible connexion between his own researches when cutting whole sections of breasts and Dr. Gye's experimental work. The subject of Paget's disease was very instructive in this connexion. In some cases Paget's disease of the nipple was the only disease discoverable in the breast. He trusted that in the discussion the consideration of benign tumours would not be excluded. For instance, in fibro-adenomata of the breast there were different forms of growth, and they varied in kind because they affected different tissues. It seemed no argument against a process being infective because one form of irritation might affect different tissues in a different manner.

Mr. J. Jackson Clarke showed on the screen drawings of microscopical bodies found by him in various tumours which, he claimed, resembled those demonstrated by Dr. Gye and Mr. Barnard. He believed them to be of parasitic origin. He then showed drawings indicating the budding process in molluscum contagiosum.

Sir Almroth Wright, answering the President's invitation to speak, said he did not think anyone was in a position to make a contribution on the subject unless he had been himself doing work on the same lines. When speaking of a cause in medicine, it should always be remembered that many factors contributed to the result. No doubt Dr. Gye had found some of the factors in cancer, but not all of them yet. Bacon used to make a distinction between experiments of light and experiments of fruit. Dr. Gye had not yet made experiments of fruit—i.e., in the way of being useful. Experiments of light were now going forward in regard to cancer, and some of them might at present bring darkness. The suggestion that by injecting a filtrate into connective tissue a tumour of complex structure could be produced was strange to him. At present he could only wonder at the extraordinary skill of these experiments, which enabled one to go away and feel that much had been done which would throw light on the subject of cancer.

Sir Charles Ballance said that for many years he was associated with the late Prof. Shattock in a study of the intimate pathology of cancer, but all their results were negative. As many of the speaker's family had died from malignant disease, he determined, as a student, to study the intimate pathology of that disease, and his work in that way enabled him to appreciate highly Dr. Gye's work. It seemed likely that it was upon this work that all progress in knowledge on the nature of cancer would in future rest.

Dr. Wm. Cramer, speaking as one who had been engaged in the experimental study of cancer, said his feeling on learning of Dr. Gye's results was one of relief from a number of difficulties which had seemed to be insoluble, particularly those which were associated with sarcoma in the fowl. Some got over that difficulty by declaring this was not a malignant new growth because it could be propagated without the transplantation of living cells. The chief point about the fowl tumour was that it was more malignant than was the ordinary animal tumour. And Dr. Gye had convincingly demonstrated that two factors were concerned, not one, and one of the two factors could be substituted from other tumours. There had been much discussion as to whether the cause of cancer was a living virus, or whether it was a chemical substance, but that was of secondary importance in comparison with other aspects of Dr. Gye's work. When one was dealing with a practically invisible virus it was easy to say it might just as well be a chemical substance, but it was for those who held that view to explain how the virus was able to multiply itself in a test-tube. It was not easy to reject a view which one had held during the best part of one's life, and he had found it difficult to do so in the case of cancer, but careful pondering on the matter had made him a convinced follower of Dr. Gye.

Mr. Zachary Cope asked whether Dr. Gye had studied to any extent the relationship of benign to malignant tumours. Often it was difficult to know whether a tumour was benign or malignant unless a very careful microscopical section was taken, and he wondered whether Dr. Gye had had the opportunity of seeing if either of the factors concerned was ever present in such tumours as fibromyoma of the uterus or a large chondroma of the femur. Either of those tumours might grow rapidly and present characters which were not malignant, but which showed that there was a rapidly acting factor at work in the organism.

Dr. H. J. B. Fry said he had done one experiment recently which was of interest in the present connexion. Into the left breast of a fowl was injected 0·5 c.cm. of a subculture virus with 0·5 c.cm. of chloroformed extract, and into the right breast 1 c.cm. of chloroformed extract, high up, and into its lower half 1 c.cm. of virus. Curiously, in the left breast no tumour developed, while in the right breast no tumour formed at the site of either inoculation, but midway between them a typical localised growth appeared, and there was extensive metastasis in the lungs. He presumed there must have been material spreading from both foci, which intermingled and formed a tumour. The growth took two months to kill the fowl.

Dr. Helen Chambers asked whether Dr. Gye kept his original cultures still growing. She had herself been working with a Jensen sarcoma for 17 years, and it could still be propagated. In those 17 years only one case of spontaneous cancer in the rat had occurred, though the animals lived in close quarters, rendering communication of the disease readily possible.

Dr. Gye, in reply, said the direction of inquiry suggested by Mr. Cope was now being followed. There was no sharp line of demarcation between benign and malignant tumours. Most of the tumours of the lower animals were relatively benign, and only rarely did they form metastases. The only really malignant one was that described by Peyton Rous. In reply to Dr. Chambers he had not thought it necessary to keep the original cultures going; it was very difficult to keep them long free from contamination, and when they became contaminated their value disappeared.

# MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

A MEETING of this Society was held on May 28th, Colonel L. W. HARRISON occupying the chair.

Mr. JOHNSTON ABRAHAM opened a discussion on

### *Marriage and Gonorrhœa.*

He began by reviewing the ideas about gonorrhœa entertained during the last 300 years. Many of these views, he said, had fallen into the limbo of forgotten things, but some of them were still held by laymen, and it was both instructive and humiliating to realise what conceptions were current even as late as the 'eighties. Leviticus XV. gave the views of Moses, the greatest medical officer of health of his time. Galen believed that the discharge in the male was caused by a flow of diseased semen from the vesicles and prostate, and did not seem to have recognised that the disease affected women at all. Galen's idea was firmly held in this country until the reign of George I. The first person to dispute it was a London surgeon, William Cockburn, who believed that the discharge was due to an ulcer inside the urethra, a view which prevailed until the time of John Hunter. Until that time it was considered that pus could not arise anywhere in the body unless there was an abscess or ulcer; this John Hunter disproved. In 1753 eight men were executed, two of whom were known to have gonorrhœa in severe form. The bodies of these two were procured, and a very careful examination of them failed to disclose any ulcer; the urethra merely appeared a little bluish, especially near the glans.

The heresy that syphilis and gonorrhœa were the same disease persisted for a long time. When the great epidemic of syphilis occurred at the end of the fifteenth century, the New Disease, syphilis, so overshadowed gonorrhœa that what was known about the latter was almost forgotten. Syphilis broke out at the Siege of Naples in 1494, and by the year 1500 it had reached Stockholm Paracelsus, in 1530, said that gonorrhœa was simply a preliminary symptom of syphilis, and in that, unfortunately, Ambroise Paré supported him, and even Sydenham accepted the statement as a proved fact. When it was found that many cases of gonorrhœa got well under local treatment without showing general symptoms, a compromise was suggested in the theory that there were two types of venereal disease, simple and malignant gonorrhœa. The view held when John Hunter came on the scene was that if the discharge were cured too quickly by the use of astringents, the purulent matter from the internal ulcer was driven inwards, and caused a constitutional taint. From 1767 to 1800 practically every case of gonorrhœa was treated with mercury, the patient being inoculated with mercury until he salivated; he was not regarded as being sufficiently under the influence of the drug until he was spitting three pints a day. If the surgeon on his morning visit found less than that, he gave orders that the mercury be pushed further, and it was a common practice for patients to add water to make up the quantity. This treatment persisted well into the nineteenth century. In 1878 James Lane, in his Harveian Lectures, said that though gonorrhœa was generally caused in the male by contagion from the female, yet it often developed when no disease could be discovered in the female partner, and he agreed with the view that it could occur merely from sexual imprudence and excess and from alcoholic indulgence. Even four years after the discovery of the gonococcus the disease was said to arise in the male from intercourse with women who had not got it themselves. There was a very great increase in gonorrhœa from 1850 to 1880. In those days endocervicitis was regarded as mere cervical catarrh. Even now that fallacies about the disease had been exploded, some old-fashioned practitioners still believed in the alum douche for women suffering from gonorrhœa.

Mr. Abraham then turned to the question, When could a person be considered so free from the disease that it was safe to enter into conjugal relations? *In the male, the morning urine when centrifuged* should be free of pus cells and organisms—he preferred to say organisms, rather than gonococci, as the presence of other organisms was sometimes as dangerous to the patient as that of gonococci. Some of these organisms, he believed, were now more pathogenic than formerly, perhaps because there was a lessened body resistance to them. He was not so keen on the importance of urethral shreds in the specimen. Mucorrhœa might be present, but this slowly declined as the infectivity passed away, and he believed that many patients were treated too long, merely because mucorrhœa persisted. Over-treatment and over-instrumentation sometimes damaged the urethra permanently. Another very useful test of cure was exercise. When the urethra had been clear for a fortnight the patient was allowed to take exercise. During the war it was found that mounted soldiers could not be cured of gonorrhœa while they continued to ride, and during treatment exercise must be reduced to the minimum. If after exercise the patient was still clear, he, the speaker, massaged the urethra on a straight sound and the posterior urethra on a flexible bougie, afterwards examining the secretion by smear and culture. If a man passed those tests he had a provocative vaccine given him. This was repeated in three months. He did not examine a patient with the urethroscope until he had remained clear for three months, as it was easy to abrade the mucous membrane. He definitely objected to injecting silver nitrate, and to give a man beer to see if it made him worse was only putting him back unnecessarily.

In the female a decision was more difficult; it was very hard to say when a woman was cured of gonorrhœa. Moreover, there was always the possibility of pregnancy occurring. At one time he used to think that a clear cervical secretion meant safety, but he did not think so now. There were only two infallible indications of a woman having gonorrhœa—namely, gonococcal inflammation of the male urethra or of a child's *conjunctiva. To be sure of a cure, all clinical* signs of the disease must have disappeared; there must be no induration of Bartholin's glands, and the urethra must be normal on inspection and palpation at vaginal and urethroscopic examination. Skene's ducts should show no sign of inflammation, nor should vagina and cervix. It was impossible to know clinically whether a woman was cured of the disease or not; bacteriological tests must be relied on and smears must be taken from every likely site. Both before and after injection of a provocative vaccine these smears should be negative. In the female the reaction from the provocative injection was not so severe as in the male. He had always found smears more reliable than cultures, though he knew it was otherwise with some workers. It was very difficult anyhow to find the gonococcus, and, therefore, every likely means should be employed.

Mr. Abraham discussed the complement-fixation test in some detail. He regarded it as a very valuable test. A persistently positive complement-fixation test indicated that the patient had a focus, probably quiescent. He quoted the case of an old gentleman who had gonorrhœa 15 years previously, was now suffering from gonorrhœal iritis, and gave a positive test. The focus might be in a joint, in the vesicle, in a closed tube, or in the epididymis. A positive complement-fixation test *did not justify forbidding* the patient to marry. A widow with tubes closed by gonorrhœa did not infect her husband when she married again, and every case must be judged on its merits. To be on the safe side, a negative complement-fixation test should be accompanied by absence of physical signs before permission to marry was given.

### *Discussion.*

Dr. O. F. PEDROSO (Brazil) said that gonorrhœa had been studied too much, perhaps, from the local point of view. There was a lowered resistance in these patients to urethritis, due to chemical attenuation of fluids of the body. In cases in which it was impossible to remove the discharge he had always noted a defect in the respiration. For its continued existence the *gonococcus required a certain pressure of carbon* dioxide, and it might well be that increased virulence of that microbe was due to increased pressure of $CO_2$ in the patient's blood. Probably exercise and the consumption of alcohol made patients worse because they produced an excess of carbon dioxide in the blood, giving in that way a better medium for the growth of the organism.

Dr. J. E Sharp said he could produce a brisk local reaction in patients by using almost any vaccine. He did not consider the presence in the discharge of organisms other than the gonococcus of so much importance as did Mr. Abraham; he had allowed such people to marry when gonococci were no longer present, and in the course of years there had not been any infection.

Dr. H. M. Hanschell said that he used to think that people who had a non-specific urethritis were safe, but latterly he had known of cases in which men had developed non-gonococcal urethritis from sexual union in the ordinary way. Such cases were very difficult to cure, especially when there was a slight discharge of pus cells and the urethroscope revealed a polypoid condition in the distal part of the urethra. He had tried various treatments, such as autogenous vaccines, touching up the excrescences with silver nitrate, and with the electric cautery, but without benefit. Ionising the urethra with zinc sulphate was the only means which brought even partial success.

Dr. W. J. Fenton agreed as to the great difficulty of curing secondary infections of the urethra, especially those due to streptococci.

Squadron Leader T. C. Morton asked if it was the experience of members that non-specific urethritis ever led to epididymitis. He had seen one case of *B. coli* urethritis. He refrained from treating it with alkalis, the condition spread to the kidney, and the man was acutely ill for a time.

Colonel E. G. Ffrench said that it was well known that a man could be more easily cured of gonorrhœa than could a woman. Sometimes when coitus was resumed the wife reinfected the man with the disease. The use of condoms for a long period was resented by most partners. A medico-legal point of some importance arose when a surgeon gave permission for a man to marry and then the latter infected his wife, for the question of divorce proceedings might arise.

Major E. C. Lambkin said that the gonococcus was the cause of much damage to other tissues. Many mild cases were left with a gleet, and in most cases the gonococcus was found eventually, as also in chronic cases of epididymitis and prostatitis. He did not like the injection into the urethra of such irritants as silver nitrate. At Woolwich for some time now a gonococcal endotoxin had been used. 960 gr. of sodium bicarbonate per diem had been of great help in clearing acute cases, but stimulation by giving $CO_2$ had been stopped as it facilitated the growth of the gonococcus.

The Chairman said that infection by *B. coli* depended largely on whether or not there was any breach of surface of the mucous membrane, also on whether the membrane had previously been attacked by the gonococcus. The latter contingency allowed the organisms to get a deep foothold. He agreed as to the difficulty of curing the so-called sago-body condition of the anterior urethra, and shared the dislike of other speakers of the use of silver nitrate on the urethra. Sometimes the only indication of gonococcal infection was a positive complement-fixation test.

Mr. Abraham replied.

---

Royal West Sussex Hospital.—The annual report says that some of the wards will have to be closed unless there is a substantial increase in regular income. The Board is considering a scheme of weekly contributions. There has been a remarkable increase in the work of the hospital, although the population remains nearly constant. The year's deficit was £2758 and investments are to be sold to liquidate the amount. There are 100 beds.

# Reports and Analytical Records.

## (1) EXTRACT OF COD-LIVER OIL; (2) PHOSPHO-LECITHIN.

(Henry K. Wampole and Co., Perth, Ontario, Canada; Agents: Francis Newbery and Sons, Ltd., 31–33, Banner-street, London, E.C. 1.)

The first of these products is an extract of fresh cod livers, the oily and fatty portions being eliminated. This is combined with fluid extract of wild cherry bark and compound syrup of hypophosphites. The combination is a nutritive tonic and stimulant which has been in use for over 40 years. The preparation is put up in 6-oz. and 15-oz. bottles, the dose for adults being one tablespoonful, for children from 5 to 12 years one teaspoonful, and from 1 to 5 years one-half teaspoonful, mixed in all cases with plenty of water. The preparation contains strychnine in the proportion of 1/80 gr. to each tablespoonful.

Phospho-lecithin (Wampole), which is recommended in depressed conditions of the nervous system, is stated by the manufacturers to contain in each fluid ounce sodium glycerophosphate 8 gr., calcium glycerophosphate 4 gr., potassium glycerophosphate 4 gr., strychnine glycerophosphate 1/60 gr., lecithin 1/16 gr., avenin 1/30 gr., and alcohol 14 per cent. It has also been before the medical profession for many years. As a restorative after injury or disease and during convalescence it should prove a valuable adjuvant to treatment. It is put up in 8-oz. and 16-oz. bottles. The dose for adults is a dessertspoonful four times a day, preferably before each meal and before retiring, and for children from one-half to one teaspoonful according to age. It will be noted that there is 1/240 gr. of strychnine in each dessertspoonful of the mixture.

## THYROXIN TABLETS.

(British Drug Houses, Ltd., 16–30, Graham-street, City-road, London, N. 1.)

Thyroxin is an iodine derivative of tryptophane, containing about 65 per cent. of iodine, and is regarded as the active principle of the thyroid. Only a very small proportion of thyroxin is contained in the glandular substance—it has been stated that 4 cwt. of the substance is required to produce 1 g. of thyroxin —and the process of extraction is complicated. Hence pure thyroxin has only been available at very high prices. The British Drug Houses, Ltd., are now offering the sodium salt of pure thyroxin, in the form of tablets, at a price which they believe will place the product within the reach of the medical practitioner who prefers to use a thyroid preparation susceptible of exact standardisation. B.D.H. thyroxin tablets are put up in bottles of 100, each containing 0·2, 0·8, or 2·0 mg. of the pure salt.

## ENERGEN CASEIN BREAD.

(Therapeutic Foods Co., Energen Works, Willesden, N.W.)

The box examined contained 12 rolls each weighing 1·14 oz. On analysis the following results were obtained:—

| | | |
|---|---|---|
| Altered starch (carbohydrate) | 41·29 | per cent. |
| Proteins | 43·75 | ,, |
| Moisture | 8·41 | ,, |
| Ash | 0·04 | ,, |
| Fat | 2·48 | ,, |
| Crude fibre | 0·10 | ,, |

"Energen" does not claim to be starch-free, but it is much lower in carbohydrates and proportionately higher in proteins than ordinary bread. We examined "Energen" two years ago, and, whilst the carbohydrates are now a little lower, the protein is 7¼ per cent. higher. The composition of this bread will be appreciated by physicians who are concerned with devising suitable dietaries for diabetic patients.

# Reviews and Notices of Books.

### THE NEMATODE PARASITES OF VERTEBRATES.

By WARRINGTON YORKE, M.D., and P. A. MAPLESTONE, M.D. London: J. and A. Churchill. 1926. With 307 illustrations. Pp. 536. 36*s*.

TO-DAY the science of helminthology has a recognised place among the ancillary sciences of medicine. Many important diseases of man, particularly those of tropical countries, are due to worm parasites, and the medical officer is expected to have as clear a knowledge of their mode of spread and prevention as of their treatment. The parasites of man do not, however, form a concise group, but are members of genera which are found represented often by numerous species in other animals; in some cases the forms which parasitise man are normally found infesting one or other of the domesticated animals. A knowledge of the helminth parasites of vertebrates in general must, therefore, be of value in advancing that of the particular forms which occur in man.

The volume compiled by Prof. Yorke and Dr. Maplestone sets out in a clear, succinct, and well-illustrated manner present-day conceptions of the classification of nematodes. It also provides for those who are acquainted with the terminology of nematode morphology and the structures which these terms signify, and care to rely upon the somewhat treacherous method of keys, a rapid means of placing many of the forms found parasitic in the vertebrates in their proper genera. The novice will probably find the volume beyond his capacity, especially if he is out of reach of supervision and of libraries where he can consult the literature. To the medical man interested more especially in the life-history and geographical distribution of nematodes the work will prove disappointing, for neither of these subjects is dealt with. He will be puzzled, and it is salutary that this is so, to find the insignificant place taken by the forms found in man. He will probably conclude that, after all, he is more likely to succeed in arriving at a diagnosis through the somewhat empirical method of the host list than by attempting to sort out his material with the aid of a formal classification such as that followed in this volume, which ignores knowledge of the host, yet occasionally has to fall back on a knowledge of the particular organ in which the parasite lived. However this may be, the work will be examined with interest by many workers in preventive medicine as well as by a large circle of professional zoologists. To the experts among the latter the book will doubtless prove an invaluable work of reference.

A suggestive foreword is written by Prof C. W. Stiles, of the United States Public Health Service, to whose Index Catalogue of Nematodes the authors pay special tribute as a volume without which, they admit, their own work would have been an impossible undertaking.

---

### COMMON SENSE AND ITS CULTIVATION.

By Dr. HANBURY HANKIN, M.A., late Fellow of St. John's College, Cambridge. With a Foreword by Dr. C. S. MYERS, F.R.S., Director of the National Institute of Industrial Psychology London: Kegan Paul. 1926. Pp. 289. 7*s*. 6*d*.

THIS book is a defence of intuition, an intuition based upon data which have been acquired and forgotten and are yet available to the mind without being recalled to consciousness. This intuition is often hampered by the trammels of reason, and even to seek for those reasons may be unwise. The author cites examples of such unwisdom, but provides the best example himself when he proposes on page 8 to consider a large number of proofs of the existence of subconscious data. Writings on the theory of the unconscious—with which he has at some time been familiar, as shown on page 3—provide evidence of forgotten material by describing how it has been brought into consciousness, but such *proofs* are *not* offered here; instances are given instead which might sometimes be explained by the hypothesis of subconscious knowledge, but in some of which the existence of this knowledge is specifically denied, as in the case of the successful man who "was always ready to turn to a thing about which he knew practically nothing provided his business instinct told him there was a chance of coining money." If the curious reader asked for a definition of business "instinct" the author might, quite consistently, reply that both the definition and the instinct are matters of common sense.

The author's main thesis is that the educational development of interest and conscious reasoning is destructive to the formation of intuitive judgment. A great part of the argument is derived from the success of business men without this training; the trained expert does the drudgery whilst the intuitional business man makes the money. A classical education has the advantage that, being trivial and uninteresting—this is the author's estimate of it apparently—it provides practice in forgetting, and scientific training is to be condemned since it involves constant reasoning and is often highly interesting. A notable suggestion is that the worldly success of Quakers is not due to their industry or honesty but arises from the incompatibility of their tenets with profane reason; this, being to them a matter of daily experience, led them to follow intuition in business as well as in the religious life.

The author's views, often appearing paradoxical, concern mental processes which academic psychologists have explored from another side. Psychology is accused of dethroning reason, and now Dr. Hankin takes a hand in the overthrow. The late Prof. Varendonck studied his own unconscious processes, and Dr. Hankin makes points of contact with him, and many sound critics agree with the thesis that we destroy some natural abilities by our educational methods. But the mental drive to effort in certain directions is not recognised here; Jung's work on temperamental types, which includes a study of the successful business man and the humble expert, suggests that something other than education decides the choice of aims and methods. Provocative and open to much criticism, the book is to be recommended to the deriders and worshippers of common sense as well as to those who study it.

---

### DISEASES AND HYGIENE OF WARM CLIMATES.

*Krankheiten und Hygiene der warmen Länder.* By Profs. Dr. REINHOLD RUGE, Dr. PETER MÜHLENS, and Dr. MAX ZUR VERTH. Leipzig: Dr. Werner Klinkhardt. 1925. *Pp.* 401. *M.*30.

THE revised second edition of this text-book forms a useful contribution to the literature on tropical diseases. The authors have attained their object, which was to compile a handbook which will be useful to practitioners in the tropics; It will also be a valuable addition to the library of the student. In fact, the volume supplies readers with a lucid, compact, and comprehensive description of diseases, their methods of transmission, and treatment. In order not to overburden the text, a generous use of illustrations has been employed with great advantage. The figures, photographs, and plates are, in most instances, well chosen and beautifully reproduced on good paper. The charts of Prof. Fulleborn, illustrating the various life-histories, are welcome because they present to students of parasitology and hygiene a graphic picture of the transmission of the more important and common diseases of man in the tropics.

In the opening section on hygiene the subject most adequately dealt with is housing, and this is followed by a short, clear, and well-illustrated account of the study of blood. Malaria naturally receives a detailed description. The parasites, the insect vectors, and the clinical aspects are fully figured with the aid of maps, charts, drawings, and photographs. In this section, which on the whole is very well done, we would point out a mistake which ought to have been corrected. The parasite of subtertian malaria is here named *Plasmodium immaculatum*, whereas *Plasmodium falciparum* is its correct name; moreover, it would be well to give a complete list of synonyms when discussing the *Plasmodia*, otherwise students are apt to become confused. Sleeping sickness, oriental sore, and kala-azar are described, and a good account of dysentery follows. The chief flagellates and ciliates of the human intestine are shortly dealt with. It seems an oversight not to illustrate *Isospora belli* (syn. *Isospora hominis*), which is certainly the commonest coccidian parasite of man and possibly the only one of pathogenic importance. The chapters on spirochætal diseases—namely, yaws, noma, acute infective jaundice, and yellow fever—are carefully presented, and the beautiful selection of photographs depicting the clinical features of yaws deserves special praise.

Of helminthic infections the authors have considered those which, in certain areas, are widely spread, and thus of great importance in the public health of communities in hot countries—e.g., ankylostomiasis, bilharziasis, and filariasis. Fig. 321 on page 326 is misleading in that three shells, a knowledge of which is important in the investigation of bilharziasis, are not drawn to scale, and their relative sizes are incorrect. This is an important matter in their identification. Sprue, beri-beri, and pellagra receive attention, and Malta fever, plague, and leprosy are carefully described; a short account of the various vegetable and animal poisons concludes the volume.

While more detailed attention might have been given to some of the subjects dealt with, on the whole the authors have shown judgment in emphasising those diseases which are of most importance in the tropics from the public health point of view. The work is likely to be of great value to the student of tropical diseases.

---

## SURGERY.

*Die Chirurgie.* A Comprehensive Presentation of General and Special Surgery. Vol. I., Section VII. Editors: Prof. KONIGSBERG and Prof. NORDMANN. Berlin and Vienna: Urban and Schwarzenberg. 1926. Pp. 936. M.17.

THIS book forms a small section of the first volume of a new systematic surgery, of which only a few numbers have so far appeared. It is characterised by the extraordinary thoroughness and elaboration of detail which is distinctive of the German mind. But though it would be a laborious book to read, this very elaboration makes it exceedingly convenient as a work of reference. The first 140 pages are devoted entirely to the subject of sutures and methods of stitching. Exact details are given for the preparation of various sutures, and especially those of catgut and of silk. For the former the iodine method is most favoured, and many of the details given will be found of great practical value. Various methods of tying knots are described in great elaboration with very neat thumb-nail illustrations which should appeal to the surgeon with a flair for technique. The remainder of the article describes in detail every possible method of suturing every known kind of tissue, even bones and blood-vessels, and one or two exceedingly neat devices are illustrated.

The second half of the book deals with the general pathology of septic and special infections. The various paths of infection and the reactions of the body, both local and general, are described, and the latest views on immunity, prophylaxis, and sero-therapy discussed. Bacteriology is considered from a surgical standpoint, those points being stressed which are of practical importance, whilst the simpler laboratory methods are clearly described. Much attention is paid to infective gangrene, and there are several good coloured illustrations of gas gangrene. In the special section, tetanus, diphtheria, anthrax, and other special infections are described, and the article concludes with an account of the pathology of tubercle and syphilis. The author has condensed into a short space a large amount of information, but the arrangement is so well ordered and the descriptions so clear that reference is easy, and the reader can rapidly obtain such precise information in advanced pathology as is not available in ordinary surgical works. The illustrations are excellent throughout.

---

*Manual of Surgery.* By the late ALEXIS THOMSON, M.D., F.R.C.S., and ALEXANDER MILES, M.D., LL.D., F.R.C.S. Vol. I. Seventh edition. London: Humphrey Milford, Oxford University Press. 1926. Pp. 565.

THIS volume is the first of two forming the seventh edition of this well-known text-book. The great success with which the book has met is sufficient guarantee of its value, but we cannot refrain from congratulating Mr. Miles on the results of the last revision. Whilst retaining all its old familiar characteristics, the book has been brought well up to date, and a surgeon must be hard to please who would ask that more information should be condensed into its 550 pages. The articles present clearly all the elementary facts of the conditions with which they deal, while the advanced student preparing for the higher examinations might well use this volume as the foundation of his studies. Indeed, if he has mastered all that it contains he need fear no examination or examiner. The articles on infective processes and on bones are especially good and will be read with pleasure and with profit by many an experienced surgeon.

---

*Thérapeutique Chirurgicale.* By P. LECÈNE, Professor in the Faculty of Medicine, Paris, and R. LERICHE, Professor in the Faculty of Medicine, Strasbourg. Vol. III. Paris: Masson et Cie. 1926. Pp. 645. Fr.60.

THIS three-volume text-book of surgical therapeutics has some unusual features. For instance, the details of operations are not described, since the authors believe that this should be the function of text-books of operative surgery. Assuming a knowledge of pathology, symptomatology, and diagnosis, they deal with therapeutic principles, and having formulated these principles, they give the indications for surgery. They describe how the indications can be met by operative means and finally give results of such procedures. The third volume deals with the abdomen and genito-urinary tract, male and female. There are no pictures. The authors regard a therapeutic decision as an intellectual act and disapprove of such short cuts as are suggested to the mind of the reader by illustrations. The recommendations offered in the text seem to be based upon experience and often include a personal touch. The book as a whole is attractive, easy, and interesting to read, and is a good guide to modern surgical therapeutics.

---

## X RAYS AND RADIUM.

*An Introduction to the Study of X Rays and Radium.* By HECTOR A. COLWELL and CECIL P. G. WAKELEY. London: Oxford Medical Publications. 1926. Pp. 220. 10*s.* 6*d.*

THIS book purports to give a lucid account of the basic physical principles of radio-diagnosis and radiotherapy and succeeds well in this aim. The ever-widening circles of our knowledge of radiology and physics have overlapped, and it is to this area of overlap that the authors have confined themselves without trespassing into the realm of either pure physics or pure radiology. The subject-matter has been carefully arranged and the explanations of the various physical phenomena and theories are clear and easy to follow.

The first part of the book deals chiefly with X rays and the second part with radium. An account of the broad principles of radio-technique is given, and the physical reasons for the procedures are explained. A useful and interesting chapter is included on the atomic theory; it gives a clear and simple account of the present state of our knowledge and is not too technical. References to suitable literature are given throughout the book for those readers who wish to pursue the subject more deeply than it has been the purpose of the authors to go. The volume concludes with a copy of the Protection Committee's report and several useful appendices. It should prove of considerable value to students taking their radiological diploma and to others who wish to gain a knowledge of the general principles of X ray and radium work, and will prove invaluable to general practitioners and others who require a solid grounding in radiological principles and who have not the time to extract their knowledge from the standard text-books.

The book is well published and can be thoroughly recommended.

### Testicular Grafts.

*Étude sur la Vieillesse et le Rajeunissement par la Greffe.* By Dr. Serge Voronoff. Paris: Gaston Doin. 1926. Pp. 213. Fr.15.

Dr. Serge Voronoff is a prolific writer on the subject of testicular grafts. This book contains much that has been previously published in his other works on the subject, but he has here confined his attention to the action of grafts in old age. The preliminary chapters deal with the pathology of senescence and with the question as to whether it is possible by any process to lengthen the span of life of the tissue cells of the body. He then attacks the relationship between the testicles and old age, and summarises the results of various forms of grafting. The book concludes with a description of the author's own results, both in animals and in human beings. Dr. Voronoff's works have been reviewed more than once in this journal, and it is perhaps unnecessary to restate the criticisms and the comments that have been noted in previous reviews. The subject is one of universal interest, whether or not the reader is convinced by Dr. Voronoff's enthusiasm. The work is well supplied with plates showing the results of grafts on various old animals and old men.

### Plague Pamphlets of Thomas Dekker.

Edited by F. P. Wilson. Oxford: The Clarendon Press. 1925. Pp. 268. *9s.*

Thomas Dekker, besides being an admirable dramatist, was also what would now be called an enterprising journalist. National disasters such as an epidemic of plague have always been sources of good "copy," and Dekker's Plague Pamphlets are notable examples of this source of literature. They give a lively picture of social life during the seventeenth century; they afford opportunities of lauding the monarchy even when it is represented by two such very different monarchs as the great Queen Elizabeth and her more questionable successor; they are full of grim tales of tragedies and comedies of a macabre flavour, and occasionally they rise to heights of almost Biblical fervour in their exhortations to repentance and to a cleanly life, and in rhapsodies upon the gains by death in leaving the miseries of this present world and upon the joys of Heaven. Mr. Wilson's notes are models of what notes should be, and will be found most helpful, for Dekker is an author whose writings are difficult for modern readers. Six plague pamphlets are given—namely, The Wonderful Yeare; Newes from Graves-end; The Meeting of Gallants; A Rod for Run-awayes; London Looke Backe; The Blacke Rod and the White Rod. The Wonderful Yeare was the year 1602–3. It must be remembered that the historical year began on Jan. 1st, but the civil and legal year on March 25th, so that Queen Elizabeth, who died on March 24th, died, according to civil and legal reckoning, in 1602, but according to historical reckoning in 1603. The Wonderful Yeare was written, as is shown by internal evidence, when the plague was declining—i.e., in the late autumn of 1603. It would be interesting to know how many people read these pamphlets, for some of them at any rate, notably a Rod for Run-awayes, are anything but conducive to that peace of mind which is always to be sought for in epidemics. But the exhortations to those who would fly, not to do so, are admirable. In London, Looke Backe (p. 188) is some excellent advice on the duty of consulting a physician and not a quack, and the peroration of The Blacke Rod and the White Rod is a magnificent bit of English worthy to rank with *Manchester al Mondo* or the well-known meditation upon death in Chapter LXI. of "Vanity Fair."

---

## JOURNALS.

Quarterly Journal of Medicine.—The April number contains the following articles: Pathological Variations in the Serum Calcium, by G. H. Percival and C. P. Stewart. The blood-serum calcium was estimated both in normal individuals and in those suffering from various complaints such as rheumatoid arthritis, diabetes mellitus, nephritis, epilepsy, tetania parathyreopriva, and various skin lesions. The effect of administering parathyroid extract and calcium salts on the serum-calcium content was also determined, and the results obtained are given.—The Purgative Action of Magnesium Salts, by Henry Cohen. Using an accurate method for the estimation of magnesium in small quantities of serum, the author shows that the purgative action of magnesium salts is exerted independently of the absorption of magnesium into the blood.—On the Hydrogen-ion Concentration and Some Other Properties of the Blood from Two Cases of Auto-toxic Enterogenous Cyanosis, by J. Barcroft, H. Dryerre, J. C. Meakins, T. R. Parsons, and W. Parsons. Observations on the blood in cases of auto-toxic enterogenous cyanosis have been previously chiefly concerned with the detection of abnormal varieties of hæmoglobin or the presence of micro-organisms. In this paper an account is given of two cases of the disease and of the investigations carried out on the blood in respect to its oxygen saturation, oxyhæmoglobin curve, carbon dioxide combining power and hydrogen-ion concentration. The oxygen saturation was found to be below normal in both cases.—The Functional Pathology of Nephritis, by E. B. Mayrs. The recent work on the physiology of the kidney and the pathology of the two main types of nephritis is discussed. In hydræmic nephritis loss of protein probably occurs through damaged glomeruli, and the tubule cells, although slightly impaired, give a normal response to the urea-excretion test for renal function. In azotæmic nephritis many of the glomeruli retain their permeability, whereas the tubular concentration function is considerably modified. Experimental evidence supporting these views is given in the article.—The Inheritance of Epilepsy, by W. Russell Brain. The opinions held from time to time as to the inheritance of epilepsy are reviewed, and fresh observations are added, based on an investigation of a series of over 200 epileptics. A family history of epilepsy was found in 28 per cent., as compared with about 10 per cent. in a control series. It was further noted that epilepsy begins more frequently in the first decade of life in those cases in which there is a family history of the disease. Early convulsions are also more likely to occur in epileptics and are more common in those who also have a family history of epilepsy. It is concluded that a predisposition is an ætiological factor in the disease.—The Spasm of Tetany Considered as a Disturbance of the Physiology of Muscle, by J. P. Martin. In accordance with recent work on the physiology of muscular contraction the author proceeds to an exposition of his thesis that the spasm of tetany is intrinsically myogenic in origin. Alkalosis, a lowering of the blood calcium or a deficiency of glycogen are factors which lead to an increase in the breakdown of lactacidogen, the precursor in the muscles of lactic and phosphoric acids, which are believed to cause muscular contraction. In tetany deficiency of calcium or a lowering of the hydrogen-ion concentration is usually present. The actual distribution of the spasm may depend upon differences in the properties of the muscles themselves and of their circulation and temperature.—Early Accounts of Acholuric Jaundice and the Subsequent History of Wilson's Patients, by J. M. H. Campbell. Claude Wilson, in 1890, described acholuric jaundice occurring in six members of a family; one of these survives, a grandson of the original patient, and has been examined by the author of this paper. He was found to exhibit the classical signs of the disease. An account is also given of some of the other early examples of the acquired and familial types of acholuric jaundice, and of the original work whereby the increased fragility of the red cells was demonstrated, and the beneficial effects of splenectomy.—Heredity in Acholuric Jaundice, by J. M. H. Campbell and E. C. Warner. Acholuric jaundice is transmitted as a dominant Mendelian character, and abnormal fragility of red cells may occur in a member of an affected family without other signs or symptoms of the disease.—A Further Contribution to the Study of Congenital Porphyrinuria (Hæmatoporphyria Congenita), by Leonard Mackey and Archibald E. Garrod. The authors described a case of this nature a few years ago in this journal.[1] The boy is now 9½ years old and some further developments have occurred. He is still prone to develop hydroa vacciniforme on exposed areas of the skin, and the spleen and liver are considerably enlarged. Examination of the urine and fæces showed the presence of uroporphyrin and coproporphyrin. There was also increased activity of the bone-marrow, as judged by blood examinations. The transilluminated appearances of the fingers are shown on a coloured plate, the bones being darker than normal. The methods of detecting pigmentation of the teeth, and its causation in certain cases, is also discussed, and the article concludes with some suggestions as to treatment.—Hæmatoporphyria Congenita (Congenital Porphyrinuria): Its Association with Hydroa Vacciniforme and Pigmentation of the Teeth, by Hugh T. Ashby. The patient, who is now nearly 4 years old, was first seen at the age of 12 months. The urine has been port-wine coloured from birth, the teeth are pink, the bones of the fingers show increased coloration by transillumination, and there are some immature red cells in the blood. The liver and spleen are not enlarged, the fundi are normal, and there is no pigmentation of the eyes. On exposure to the sun hydroa vacciniforme develops; this was first noticed at the age of 4 months. A vanishing quinine cream has been used to protect the skin from ultra-violet rays, which proved helpful last summer.—Hæmatoporphyria Congenita with Hydroa Vacciniforme and Hirsuties, by A. M. H. Gray. The subject of this paper is now aged 18, but her urine was not noticed to be red until the age of 5 years, when blisters appeared on the face and hands in the summer and have recurred annually. There is a growth of long downy hair on the forehead, cheeks, upper lip, chin, sides of neck, and chest. The teeth are of a deep yellowish-brown tint, but there is no trace of pink in them on fluorescing. The liver and spleen are not enlarged, but the finger bones are dark on trans-illumination. Porphyrin is present in the blood and fæces, and blood counts, while showing no anæmia, indicate that there is marked activity of the bone-marrow. The article is illustrated by a plate showing the appearance of the patient, and a discussion is included of the causation of the hydroa and of the relation of hirsuties to the disease.—The Dextrose Tolerance Curve in Health, by R. Hale-White and W. W. Payne. Capillary blood was used in this series of observations on sugar tolerance in healthy males of varying ages. It was found that in young adults the blood-sugar after taking 50 g. of glucose by the mouth may rise to 0·2 per cent., and with advancing years this figure may reach 0·24 per cent. In youth the blood-sugar returns to normal in two hours, but after the age of 60 three hours may elapse before the normal level is resumed. A delay in stomach emptying was found to impede considerably the rate of return of the blood-sugar to normal.—The journal concludes with an account of the meeting of the *Association of Physicians of Great Britain and Ireland* held in London in May, 1925.

# The Services.

## ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. C. H. Dawe to the *Victory*, for R.N. Barracks, Portsmouth, and for duty with Surg. Rear-Admiral, R.N. Hospl., Haslar, as Naval Health Officer; Surg. Comdr. W. C. Carson to the *Valiant;* Surg. Comdr. H. R. H. Denny to the *Thunderer;* Surg. Comdr. F. Cock to the *Sandhurst;* Surg. Comdr. W. L. Hawkins to the *Douglas*, to be accommodated in R.N. Barracks, Devonport; and Surg. Comdr. M. W. Haydon to the *Tiger.* Surg. Lt.-Comdr. A. C. V. Green to the *Danae.*

### ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. F. L. Cassidi to be Surg. Lt.-Comdr.

## ROYAL ARMY MEDICAL CORPS.

Lt.-Col. C. W. Holden retires on retd. pay, and is granted the rank of Col.

Maj. and Bt. Lt.-Col. C. G. Browne retires on retd. pay and is granted the rank of Lt.-Col.

Temp. Capt. S. Pinion relinquishes his commn. and retains the rank of Capt.

### SUPPLEMENTARY RESERVE OF OFFICERS.

Lt. W. G. Burns to be Capt.

### MILITIA.

Capts. D. M. Marr, F. H. B. Norrie, and P. Walsh to be Majs.

### TERRITORIAL ARMY.

Maj. H. Henry, having attained the age limit, is retired *and retains his rank with permission to wear the prescribed uniform.*

Maj. (Prov.) H. Pinto-Leite is confirmed in his rank.

Capt. B. C. O. Sheridan to be Divisional Adjutant, 42nd (East Lancs.) Div. T.A.

G. Williams to be Lt.

Sanitary Companies: Capt. J. A. Bingham to command the 5th (Scottish) Sanitary Company.

### TERRITORIAL ARMY RESERVE OF OFFICERS.

Maj. H. W. Read, from the Active List, to be Maj.

## ROYAL AIR FORCE.

*The undermentioned Flying Officers are promoted to* the rank of Flight Lt.: A. Dickson and R. T. F. Grace.

Flying Officer H. M. Levy resigns his short service commission.

## INDIAN MEDICAL SERVICES.

Maj. B. C. Clifford has been appointed Medical Officer of the Kashmir Survey Expedition. Lt.-Col. C. E. Palmer, Superintendent, Central Prison, Allahabad, officiates as Inspector-General of Prisons, United Provinces, vice Lt.-Col. J. E. Clements who has been granted leave. Lt.-Col. W. A. Means takes over duties of Assistant Director of Public Health (Malariology) United Provinces. Maj. J. A. S. Phillips officiates as Director of Public Health, Bihar and Orissa. Dr. Upendranath Ray Choudhury, Teacher of Surgery, Campbell Medical School, Calcutta, has been appointed a member of Bengal State Medical Faculty for two years. Maj. H. W. Action, Professor of Tropical Pathology and Bacteriology, officiates as Director, School of Tropical Medicine and Hygiene, Calcutta, vice Lt.-Col. Megaw, on leave. Dr. Tarak Nath Sur acts as Professor of Pathology of the Calcutta Medical College. Dr. R. B. Khambata acts as Director of Public Health, Bengal, vice Lt.-Col. A. D. Stewart. Dr. B. B. Brahmachari acts as Director of Bengal Public Health Laboratory. Dr. Abdul Basir Sahib Bahadur acts as Assistant Professor of Physiology, Madras Medical College. Dr. F. G. Martin has been posted to King Institute of Preventive Medicine, Guindy. Dr. M. L. Kamath, civil surgeon, Vizagapatam, acts as Presidency Surgeon and Second Physician, General Hospital, Madras, vice Maj. J. M. Skinner. Maj.-General T. H. Symons, Director-General, Indian Medical Service, has succeeded Sir Charles McWatt as a member of the Council of State. Dr. S. C. Mukerjee, civil surgeon, has been appointed to medical and executive charge of Betul Jail.

ssues put the lower animals into a better position or individual resistance than plants have ever reached, out the selection of resistant individuals and the production of resistant races still remained their great defence as they do now among bacteria. With increasing size and complexity, longer life and restricted profusion of multiplication, the need for individual protection and cure became more pronounced, and out of the elementary capacity, which has been detected in amphibia and perhaps even in insects, birds and mammals developed the antibody response to proteins from other species round which so much recent progress has centred that its special and restricted occurrence is apt to be overlooked.

The Linacre Lecture makes it perfectly clear that we cannot hope to get at the bottom of what disease means without a comparative pathology which is more real and comprehensive than veterinary medicine. The structure of the body is meaningless if evolution has not happened, and it is comparative anatomy which has enabled us to understand what we do of it. Prof. G. ELLIOT SMITH has already contributed much to this understanding and returns to it again in the Cavendish Lecture, of which an abstract is given on p. 1081. Pathology and physiology still wait for the corresponding stimulus and illumination.

◆

## LOCAL HEALTH ADMINISTRATION: THE REVISION OF AREAS.

DUE weight will doubtless be given to the Memorandum of Evidence drawn up for submission to the Royal Commission on Local Government on behalf of the British Medical Association.[1] The Memorandum rightly urges the need of unification in the local administration of health matters. Unity of central administration was largely, if not completely, secured by the creation of the Ministry of Health and by the transfer of scattered departmental powers thereto. The next step is to apply the same process to local health powers and responsibilities. Remarkable evidence can be given as to the number of medical officers and health and welfare inspectors and nurses paid out of public funds concerned with a single family, the number of medical practitioners from whom various members of a single family may be simultaneously receiving treatment and advice, and the number of medical practitioners under whose care a single individual may come at different ages and in different circumstances. The British Medical Association states clearly its opinion that the necessary unification of local health administration cannot be attained without a radical revision of the local areas for the purpose. "The *ideal arrangement*," says the Memorandum, "would be to ignore existing county and borough or district areas altogether and to form entirely fresh areas throughout the country, each with a considerable town as a centre, associated with which should be such surrounding urban or rural areas as would most naturally or conveniently look to such town for its main hospital provision or as a focus of health administration. Within each such area there would be either one health administrative body established ad hoc, or one local government authority which, amongst its other functions, would have the responsibility for all forms of health administration."

It is, of course, the traditional English method of political development to view ideal arrangements in the light of existing institutions. Pursuing this national method we shall all presumably agree that the county will usually be too big an area for the purpose, while the small rural district with a low population and a low rateable value will not be big enough. A large extension of the county borough system would go a long way to solve the problem. More county boroughs are wanted, and the county borough must control a wider radius. The big town with a large rural perimeter has many advantages in such matters as town-planning, housing, and the supervision of milk-supply. When the application of the county borough system has punched large discs out of the map of the English counties, unsymmetrical and inconveniently-shaped areas will remain to puzzle the health administrator. Local politicians, too, will not wish to be disturbed, and they often exercise remarkable influence upon public affairs. But public opinion may be moving more readily than we imagine in the direction of the British Medical Association's plan. It is being recognised that modern curative medicine is largely institutional, and the best and most economical treatment is usually to be had in special institutions organised in relation to some large and perhaps distant town. But even the old distances of town and country are altering. Every year more of the countryside is brought within the radius of the large towns by means of improved services of motor transport. In other matters than health the old areas are being rearranged. Special educational facilities are causing a regrouping of local connexions. In the ecclesiastical world the creation of new bishoprics is adapting ancient episcopal arrangements to modern needs. In the judicial world it is realised that the immemorial system of assize towns is out of touch with present concentrations of population. In the domain of local government many changes are impending. The overseers are disappearing; poor relief is soon to depart from the lines laid down in the reign of Elizabeth; there is a movement towards standardisation; smaller units and areas are being merged in something larger and less parochial.

---

[1] *Supplement to the British Medical Journal*, May 1st, 1926, pp. 173–4.

The idea of the big town as the centre of a large administrative area for health purposes is not entirely novel. There was much clear thinking in the Dawson Report in 1920, the document which the Consultative Council on Medical and Allied Services (then newly established under the Ministry of Health Act) presented to Dr. ADDISON as the first-fruits of its labours.[1] The Dawson Report contemplated the organisation of health administration in England by means of groupings of "primary" and "secondary" health centres. The primary centres were to be the smaller towns wherein the health services and activities of their own districts would be gathered together under the supervision of staffs consisting of general practitioners. The secondary centres were to be the larger towns big enough to contain adequate equipment and an efficient staff of consultants and specialists. Preventive and curative medicine were to be brought together in each case. Certain supplementary services were to be correlated—tuberculosis sanatoriums, convalescent centres, institutions for the feeble-minded, mental hospitals, infectious diseases hospitals, epileptic colonies, and so on. Teaching and research were not to be forgotten, and the universities were to play their proper part. Like other programmes of post-war reconstruction the Dawson Report was forgotten in the subsequent period of retrenchment and reaction. It might well be studied afresh.

# PREVENTION OF SKIN DISEASE IN CHILDHOOD.

IN the vast field of child hygiene there is no corner in which the fruits of prophylaxis could be more rapidly garnered than in the domain of skin diseases, while in spite of intensive propaganda and legislation it is usually a matter of years before the improvements in housing, light, and ventilation in a tuberculous community are mirrored in the returns of the Registrar-General. It has to be granted that morbidity—for skin diseases are rarely fatal—is of less apparent importance than mortality, but the loss of time in education, to consider only one aspect, is very great. A visit to the skin clinic of any general hospital reveals the fact that at least half the cases are among children, mostly under 5 years of age, and that a majority of these are the result of direct contagion by parasites or streptococci. The proportion is probably even greater, for it must not be forgotten that most of the patients have been through the sieve of the casualty department before they reach the dermatologist, and that the milder cases are not referred. It is not difficult to give good reasons for the preponderance, for the younger the child the less its degree of acquired immunity, the more uncontrolled the "scratch reflex," and the more vulnerable the relatively delicate horny layer, while in the repeated contact of school-children with their playmates we find a very fruitful source of contagion. Whatever the relative importance of internal as opposed to external causes, it will not be denied that digestive disturbances are the common heritage of the human progeny, and that a not inconsiderable proportion of these is preventable.

We are faced, on these premises, with a problem which would appear tolerably easy of solution. But there are a number of conditionals, and of these the greatest are the spectres of ignorance and prejudice. A great deal could be done at the source, which still remains the insanitary and overcrowded home. The welfare centres and prenatal clinics have a magnificent opportunity. Apart from control and inspection there should be organised attempts to explain the why and wherefore to the young mothers, many of whom still imagine that tinea is a disease due to a hidden worm. They might be taught, as Dr. M. S. THOMSON has emphasised in a paper read at a recent meeting of the Maternity and Child Welfare Group of the Society of Medical Officers of Health, that too much clothing and too strong a soap are as frequent a source of skin trouble as neglect to provide a warm covering and the proverbial Saturday bath. Dr. THOMSON's analysis of 500 cases attending the out-patient department at the Belgrave Hospital for Children is as follows:—

| | Cases. |
|---|---|
| *Lichen urticatus* | 132 |
| Impetigo | 99 |
| Eczematous and traumatic dermatitis | 116 |
| Scabies | 30 |
| Ringworm of the scalp | 30 |
| Ringworm of the body | 18 |
| Chicken-pox | 18 |
| Pediculosis capitis | 12 |
| Ichthyosis | 9 |
| Pityriasis alba | 6 |

Of the remaining 21 cases the most important were 3 of lupus vulgaris, whilst among them were also examples of hydroa æstivale, pediculosis corporis, pityriasis rosea, erythema nodosum, erythema multiforme, molluscum contagiosum, scleroderma, mange, and psoriasis.

---

[1] Ministry of Health. Cmd. 693. H.M. Stationery Office. 1920. 1s.

The prevalence among them of lichen urticatus (strophulus) is remarkable, while the number credited to pityriasis alba seems unduly small The omission of congenital syphilis from the list is no doubt due to the fact that these cases are treated in another department of the hospital The practitioner will do well to remember the ever present possibility of such cases masquerading as harmless intertrigo, for on his circumspection may depend not only the future history of the little patient before him, but also the fate of children yet unborn There is nothing in medicine more preventable than congenital syphilis, as Dr D NABARRO emphasises in his article on its treatment which appears on p 1108 Pediculosis capitis accounted for 12 cases in Dr THOMSON's series, and he warmly recommends the treatment with 1 in 40 carbolic devised by Dr A. WHITFIELD This is, as he states, invariably successful, and if it could be enforced as a prophylactic measure in all children of school age on the same day in three or four consecutive years, it is more than likely that the parasite would become extinct In a second paper read at the same meeting and printed on p 1126, Dr A. M. H GRAY emphasised the importance of scalp hygiene. Apart from such gross infections as pediculosis and ringworm, which are likely to be spread by the indiscriminate interchange of hairbrushes and hats, it is probable that the organisms of seborrhœa are conveyed in the same way Let anyone who doubts the prevalence of this troublesome condition attend a Sunday afternoon chapel service at any large school, and place himself in a seat of vantage in rear of the juvenile congregation. Black coats form a good background for white scurf, and the observer will be struck by the high percentage of infected individuals. If it be true, as believed by many authorities, that seborrhœa of the scalp is a precursor of premature baldness in men, this most unwelcome sequel might be combated at school age with more prospect of success than when it has become established The almost invariable association of seborrhœa capitis and acne vulgaris with comedo formation suggests that here also we have a preventable sequel of scalp infection It should be the school doctor's duty to place himself in that observer's position from time to time, and call the attention of the matron or nurse to such of their charges as manifest the symptom, frequent shampoos with sulphur, salicylic, and resorcin soaps are the simplest and best treatment. It should be made a serious offence for children to use any but their own brushes, combs, and towels, and a very active supervision should be kept on the hygiene of the sports' changing rooms, whence almost all epidemics of "scrum pox" (impetigo) and dhobie itch (tinea cruris) take their origin The hairdresser's shop should be subject to periodical medical inspection and control, many of the more obvious instruments of infection, such as the machine-driven rotary brush, have been banished, but others still remain, and it would be interesting to know how often the ubiquitous clippers are taken to pieces, cleaned, and sterilised

The care of the child's skin, until it reaches the age when a personal interest and pride have been aroused, is thus seen to require the unremitting attention of midwives, monthly nurses, mothers school nurses and, last but not least, the school doctor It is to him especially that we would recommend a careful study of the question, for it is from him that the requisite knowledge, without which no progress can be made, must emanate

# Annotations.

"Ne quid nimis."

## SILICA AND TUBERCLE.

THE report upon the work of the Miner's Phthisis Medical Bureau of South Africa for the year ending July 31st, 1924, is drawn up in the form familiar to those who regularly study this important publication [1] It contains a vast amount of statistical information, the records of the Bureau now being available for eight years, and is worthy the careful attention of all who are interested in this aspect of industrial medicine The gold mining industry of the Transvaal spends about £800,000 annually in compensation to mine workers and their dependents, and the payment of all awards is based solely upon the certificates issued by the Bureau, the members of which are appointed by and responsible to the Union Government alone These officers have, therefore, a most responsible duty to perform, and we believe that it will be generally acknowledged that these duties are performed conscientiously and well

During the year under review no less than 33,775 examinations were carried out at the central office, and some 800 visits were made to various mines. As in previous years, the importance of radiography in the diagnosis of early simple tuberculosis and of early simple silicosis is emphasised. Since 1916 the Bureau has accumulated medical and radiographic records of over 50,000 European men and 14 000 natives, and it is therefore entitled to speak with a great deal of authority Nevertheless, it may well be that the difficulty of arriving at a true and complete knowledge of the condition of an individual's chest is beyond the powers of such diagnostic methods as we possess at present. The problem of the relationship of simple silicosis to tuberculosis is, of course, an extremely difficult one, very often the medical man would doubtless prefer to adopt the attitude of scientific doubt, yet by law he is required to make a definite pronouncement, and a diagnostic system once adopted is difficult to depart from. The clear-cut conception, prevalent in this country, of miner's phthisis as a form of tuberculosis occurring in individuals whose lungs have been previously damaged by exposure to silica dust is not entertained in South Africa; indeed, the very term "miner's phthisis" is never used in the Bureau, but the disease is always referred to as "silicosis," irrespective of whether it is complicated by tuberculosis or not For some time Dr W Watkins Pitchford and his colleagues have been inclining to the view that in the development of silicosis the presence of pre-existing tuberculosis cannot be neglected, and in this report they go even further On p 7 it is stated that if tuberculosis could be abolished from the mines, very few, if any, cases of silicosis would arise under the present conditions of freedom from dust. Again, on p 13, discussing the incidence of simple silicosis and its detection in one case in the primary stage—i.e, without a precursory ante-primary stage—Dr Watkins-Pitchford states that it "was probably due to an unusual activity of that tuberculous infection which, as I believe, is the exciting cause of at least the great majority of cases we class under simple silicosis." The basis of this belief seems to be the fact that cases of silicosis are still being produced, and in increasing numbers, every year (p 6), though the average dust content of underground air has fallen from 4·0 mg per cubic metre in 1915 to 1 1 mg in 1924 But it is quite conceivable that if the chemical theory of the action of silica now generally accepted be the correct one, silica is chiefly dangerous in its most finely divided state The grosser particles may have been eliminated, and, indeed, to the unaided senses the clarity of underground air leaves nothing to be desired, but the finest particles, those most easily dissolved in the tissues of the lung, still persist. It is at least as difficult to explain the incidence of silicosis under modern conditions on the assumption that the inhaled dust acts only in combination with the tubercle bacillus. There is no reason to suppose that more tuberculous recruits, either European or native, enter the service of the mines now than in former years. And although native workers are not examined radiographically to the same extent as are the Europeans, it is surely reasonable to suppose that the simpler diagnostic methods are as carefully and efficiently employed now as in days gone by. The difficulties and the enormous labour involved in the thorough initial and periodic examination of this enormous industrial population must be obvious, and there can be no doubt that a high average of success in diagnosis is attained on the Rand. Nevertheless, diagnosis is by no means a perfect science; finer lesions must inevitably be undiscoverable from time to time, and there must be a danger in developing pathological theories on a basis of clinical observations.

---

[1] Report upon the Work of the Miner's Phthisis Medical Bureau for the Twelve Months ending July 31st, 1924 Cape Town Cape Times. 1926 Pp 56 4s

Silica and its relation to the tubercle bacillus is the big problem with which the Miner's Phthisis Bureau has to contend, and we have dwelt chiefly on this aspect of the report. *But the publication contains* much other matter which is equally worthy of serious attention.

## INHERITANCE OF PERONEAL ATROPHY.

A REMARKABLE family afflicted with peroneal atrophy has recently been described by Dr. Madge Thurlow Macklin and Dr. J. Thornley Bowman.[1] It presents an excellent opportunity for study of the disease from the point of view of inheritance, since five generations are affected and 21 of the 101 persons in the direct line of descent show peroneal atrophy. These writers conclude that the condition is dominant to the normal and is not sex-linked; in a large family with one affected parent half the children are likely to develop it whether the signs are apparent at the time of procreation or not. No member of the family reported has inherited more than a single factor for peroneal atrophy, and it is not known what would be the result of inheriting a factor from both parents. The question arises whether it is safe for members of an affected family to marry, and here the present investigators give a pessimistic verdict. They say: "Although it is safe for persons having a dominant factor for disease in their family to marry if they themselves are free of it, the same cannot be said of peroneal atrophy, for one cannot tell until one is past middle age and so past the reproductive period whether one has inherited the disease. The only safe rule for all persons who are born of affected parents, or born of parents who died young, but who had come of affected stock, is either not to marry or to take absolutely safe precautionary measures against having children. This applies to unaffected as well as affected children of affected parents." Males and females suffer equally. The disease does not seem to make any difference to the longevity of the individual, but it produces very serious crippling, and Dr. Macklin and Dr. Bowman consider that strict precautions against having children are necessary because only thus can it be eradicated from the community; sporadic cases in families which give no previous history are explained on the supposition that the parents have the disease latent and would develop it in later life if they lived long enough. They comment on the fact that their conclusions differ from those of Herringham, who described a somewhat similar family in which only males were affected, the disease being transmitted by unaffected females to their sons except in one instance in which an affected father had an affected son. Apart from this one case the record of this family suggests that peroneal atrophy is sex-linked and recessive, but Herringham himself remarked that this type of inheritance is not typical of the disease except as it occurs in this particular family. The present investigators suggest that possibly the family described by Herringham was suffering not from peroneal atrophy, but from some form of distal myopathy, and that the difference of inheritance is explicable on this basis; the fact that atrophy of the forearms was an almost constant feature in Herringham's cases, but is absent in those now reported, lends colour to this suggestion. In this respect the present cases differ from those described by Charcot and Marie, and Tooth; peroneal atrophy without wasting of the forearms is a rarer type, and patients corresponding to Herringham's are more commonly met with. It is generally considered that as the disease does not usually come on later than the second decade of life it is rather unlikely that parents will develop it after their children have been born. It is possible, however, that the signs may be so slight as to escape notice during several generations, which would explain the apparently sporadic cases. A gross example might be produced by any extra strain, such as infection, thrown on cells hereditarily weak. Ormerod and Batten report cases following an attack of measles. This work of Dr. Macklin and Dr. Bowman, by comparison with that of Herringham, shows that there are, at any rate, two types of peroneal atrophy distinguishable clinically and by their method of inheritance. It shows the risk that a member of an affected family may run of giving it to his children. Probably, however, there are other types of the disease varying in severity and method of transmission, so that in isolated cases in which the family appears healthy or in which no family history can be obtained, no very definite prognosis can be given either for the patient or his offspring.

## BERNHARD HEINE: A PIONEER IN EXPERIMENTAL PHYSIOLOGY.

A PATRIOTIC if belated assertion of the claim to surgical fame of an almost forgotten German worthy deserves acknowledgment. The family of Heine was well known in South Germany through its medical members, one of whom, Johann Georg, was the founder of a celebrated orthopædic institute in Würzburg, and another, Jakob, who was ennobled and became von Heine, gave his name (in Germany at least) to the Heine-Medin disease, also known as anterior poliomyelitis. It appears that Bernhard Heine, the nephew of Johann Georg, whose daughter he married, was a pioneer of bone surgery. J. G. Heine's orthopædic institute was devoted to the mechanical treatment of deformities, and in it the making and fitting of appliances were carried out with great skill. Probably experiences in his uncle's workshops led Bernhard Heine to turn his attention to the invention of an osteotome. This ingenious but apparently complicated machine achieved a great reputation, and in 1837 Heine visited Russia on the invitation of the Emperor Nicholas in order to instruct Russian surgeons in the use of his instrument, hundreds of which seem to have been sent to St. Petersburg. With his osteotome Heine claimed to be able to perform all kinds of operations on the bones, and to remove parts of them of any desired size at any depth and in any direction. He performed a large number of experiments on dogs in order to study the processes of repair and regeneration of bone. Many of the preparations which he made are now in the Anatomical Institute of the University of Würzburg and have recently been carefully studied with the help of X rays. They form a great part of the subject-matter of a volume of essays[1] in which his pioneer work has been recalled. Despite the fact that Heine relied entirely on naked-eye appearances and that results were often complicated and processes

---

[1] Bernhard Heine's Versuche über Knochenregeneration. Sein Leben und Seine Zeit. Von der deutschen Gesellschaft für Chirurgie anlässlich ihre 50 Tagung den Fachgenossen unterbreitet. By Drs. K. Vogeler, E. Redenz, H. Walter, and Prof. B. Martin, with a preface by Prof. A. Bier. With 105 illustrations in the text and one portrait. Berlin: Julius Springer. 1926. Pp. 224. 7.50 Reichsmarks.

obscured by suppuration, it appears that he anticipated by some years the observations of Flourens and Ollier on the regeneration of bone and on the parts taken respectively by the periosteum and the bone-marrow in forming new bone. Bernhard Heine received honours from the Emperor of Austria, the Kings of Prussia and Bavaria, and the ruler of his native country of Württemberg. He became professor honorarius of the University of Würzburg, and in 1844 he was made extraordinary professor of experimental physiology. His communications to the Academy of Sciences in Paris were favourably received and won a prize for him in 1838. He died at the early age of 46 in Switzerland, whither he had gone to seek relief from pulmonary tuberculosis.

It is remarkable that the work of such a man should have been almost completely lost sight of for so many years. There is no mention of his famous osteotome or of his work on bone growth in Hoffa's text-book of Orthopædic Surgery, although Hoffa himself was a professor at Würzburg and gives a good account of J. G. Heine's orthopædic institute. Any reproaches that might have been founded on German neglect of a native hero of pathology and physiology are set aside by the publication of this interesting book, in which Heine's countrymen have fully vindicated his right to be accounted a pioneer in the investigation of the phenomena attending injuries and diseases of bone.

## BIRTH INJURIES TO THE EYE.

AT the discussion on this subject at the recent annual congress of the Ophthalmological Society[1] Dr. Comyns Berkeley, speaking for himself and the majority of his obstetric colleagues, professed profound ignorance on the subject. As a matter of fact, it is safe to say that the majority of ophthalmic surgeons have never seen a case of retinal hæmorrhage in a newly-born infant. But this is simply because an ophthalmoscopic examination of an infant within the first week of life is hardly ever undertaken. When a series of systematic observations of this sort has been carried out the results have been somewhat surprising. Drs. Ernest Thomson and Leslie Buchanan, more than 20 years ago,[2] quoted continental authorities who had observed retinal hæmorrhages following normal labour respectively in 10 per cent., 32 per cent., and 20·5 per cent. of all cases, and Dr. Thomson, in his opening remarks at the recent discussion, so far confirmed these figures that he found the percentage of Glasgow cases somewhere between 10 and 20. Mr. F. A. Juler, who had examined a series of 50 cases at Queen Charlotte's Hospital in London, arrived at a similar conclusion. The great majority of these cases are slight retinal hæmorrhages which clear up, leaving no trace after a few days. In some cases, however, the hæmorrhages, occurring at the macula, may leave permanently serious effects, and it is freely surmised that certain defects in one eye only, discovered in later life, including cases diagnosed as "congenital amblyopia" may in some instances be due to this cause. It is to be remarked that hæmorrhages are by no means confined to those cases where instruments have been used. They apparently occur in many cases of prolonged labour and non-instrumental delivery, and even in cases where labour has been perfectly normal or even premature. Obviously rules as to prophylaxis are very difficult to formulate, and we cannot complain that until this can be done obstetricians take little interest in the matter. One reason why such ophthalmoscopic examinations are not more frequently made is doubtless the extreme patience and tact required in the case of a new-born baby; but before any useful conclusions can be drawn as to their connexion on the one hand with prolonged natural labour, and, on the other, with the use of instruments, this will have to be done. Other ocular lesions occur. Apart from sensational cases which have been recorded, such as extrusion of the eyeball on to the cheek as the result of instrumental pressure, or the gouging out of an orbit by the fingers of a doctor who had mistaken it for an anus, perhaps the most interesting lesion is the rupture of the posterior elastic membrane of the cornea, described by Dr. Thomson and Dr. Buchanan first in 1903 and again at the recent discussion. In these cases there is subsequent formation of cicatricial tissue which may remain as a permanent linear scar. These scars are always vertical, or approximately so, a fact probably related to the direction of pressure by the forceps. They naturally escape notice in most cases until the child's vision is found to be defective in one eye and the corneal scar is discovered. In some cases a considerable amount of corneal astigmatism results, and it was even suggested by some speakers that some of the cases of high monocular myopia, which are not very uncommon, may owe their genesis to instrumental pressure at birth. In these cases, although a rupture of Descemet's membrane might account for a good deal of astigmatism, one would have to suppose that in order to produce a high degree of myopia in both meridia the sclera had yielded to the pressure of the forceps.

## SYMPTOMS OF CORONARY OCCLUSION.

THE literature of the interesting condition of coronary occlusion is increasing rapidly. We published a leading article in our issue of Jan. 9th last giving a brief résumé of some of the chief clinical manifestations of occlusion of branches of the coronary arteries. The case described in THE LANCET of May 1st by Dr. E. Bulmer and Dr. F. W. Mason Lamb is specially noteworthy, not only for its rarity, but also for the care with which it is described and the suggestive comments on the pathological conditions observed. The case was one of coronary thrombosis in a man 27 years of age with a past history of syphilis and of subacute or chronic nephritis with acute exacerbations. The thrombosis occurred on the site of an atheromatous ulcer in the left coronary artery. Microscopically, a widespread deposition of cholesterin and of a special type of fat was observed in some of the larger vessels, including the aorta and left coronary artery. The authors suggest that the premature death of the patient may have given an insight into the pathology of arterio-sclerosis in what may be called the pre-fibrotic stage. A critical study of the clinical features of coronary occlusion has recently been published by Dr. Louis Hamman.[1] He gives an interesting account of the anatomy of the coronary vessels, quoted largely from Gross,[2] and mentions the observation made by him that anastomoses throughout the coronary circulation become more extensive and more effective with advancing years. He suggests that, other things being equal, the heart of a man at 60 years of age is better prepared to withstand the effects of coronary occlusion than that of a man of 20. He maintains that the results of coronary occlusion depend upon the size and situation of the branch obstructed, the rapidity with which it occurs, the condition of the general and coronary circulations, and the age of patient. Dr. Hamman gives a useful classification of the main symptoms in tabular form in four groups. The first comprises the immediate symptoms of the occlusion—viz., anginal pain with shock, prostration, fall in blood pressure, and suppression of urine. The second group includes the symptoms associated with the myocardial damage—dyspnœa, Cheyne-Stokes breathing, the results of passive visceral congestion, and the disturbances of cardiac rhythm. The third is devoted to the symptoms resulting from the myocardial infarct, including fever, leucocytosis, pericarditis, embolic phenomena, cardiac aneurysm, and rupture of the heart. The fourth group is devoted to the additional symptoms referred to other systems which sometimes complicate the diagnosis, such as nausea, vomiting, diarrhœa, and those due to vasomotor and nervous disturbances. He discusses each of the main symptoms in detail and quotes illustrative cases. He stresses the importance of the embolic sequels of coronary occlusion and believes that they are of greater frequency than pericarditis, and of equally decisive diagnostic significance. Dr. Hamman gives a helpful account of the diagnosis and treatment of the condition. His paper is rendered more valuable by a useful bibliography, and we can commend it to our readers as an interesting summary of the main clinical features of this important pathological catastrophe.

## ARTHRITIC MUSCULAR ATROPHY.

THE intensity and rapidity of the muscular wasting associated with acute arthritis has long excited interest; the processes at work are evidently different from those which produce wasting from simple disuse. Miss A. E. B. Harding,[1] working in the surgical department at University College Hospital, has measured the consumption of oxygen involved. Experimental streptococcal arthritis of the knee-joint in rabbits leads to great wasting of the thigh muscles, and from her measurements it is clear that these wasted muscles use more oxygen per unit of weight than normal muscle, and in many cases more than is consumed by the whole weight of the unwasted muscle. As a control she produced atrophy from disuse by putting up the animal's legs in plaster for several weeks; wasting ensued and the oxygen consumption was diminished proportionately. It was also noticed that the arthritic muscles were much more irritable. It seems clear that in them an active katabolism is at work, and in this way they resemble overused rather than disused muscles. Raymond and others have found that section of the corresponding posterior roots prevents arthritic atrophy, so that the stimulus to excessive activity is presumably peripheral in origin.

## THE OSLO CONFERENCE ON THE HEALTH OF SEAMEN.

IN THE LANCET of Jan. 9th we referred to the initiative taken by the Norwegian Red Cross Society in establishing Red Cross medical stations for the treatment of merchant seamen of all nations in the seaports of Norway, and to the efforts which are being made, under the auspices of the League of Red Cross Societies, to extend this scheme to other countries. It was stated then that the Norwegian Red Cross hoped to organise this summer a tour of inspection of certain ports in Norway in order that those interested might study the work being done for seamen. From the June number of the *World's Health*, which is entirely devoted to articles on the health and welfare of the seaman, we learn that the proposed tour, now called an Itinerant Conference, will take place from June 28th to July 5th, and that visits will be made to Oslo, Bergen, and Trondhjem. The King of Norway has lent his patronage to the conference. Among others, Roald Amundsen will speak on the welfare of the sailor, and leading Scandinavian and other doctors are giving lectures on different aspects of the health of seamen. Prof. Almkvist's paper on "Seamen and the Venereal Diseases," and Dr. Heitmann's on "Seamen and Tuberculosis," should throw fresh light on the incidence of these diseases in the merchant service. At all the ports visited there will be special demonstrations at the Red Cross medical stations for seamen, and the delegates will be given every opportunity to see what Norway, which sends a greater proportion of her sons to sea than any other nation, is doing for her merchant seamen. The Norwegian Red Cross scheme does not propose to set up new and expensive machinery in the ports for treating disease among sailors. All that it advocates is the coördination of existing forces. A doctor in each port would undertake, under the ægis of the Red Cross, to act as medical officer for seamen, treating, at the usual rates, those complaints which come within his province, and sending on other cases to hospitals or specialists. Hitherto the sailor in a foreign port has been at the mercy of the first plausible quack to approach him, and has often not known where to turn to obtain reliable treatment. In many ports he has been more familiar with the Red Lamp than with the Red Cross. If the Norwegian Red Cross scheme becomes universal, as it is hoped that it will, the seaman will in future be sure of help and advice, whether at home or abroad.

## HISTORY OF SURGERY IN EDINBURGH.

THE opening next week of the reconstructed department of surgery in connexion with the bicentenary of the Faculty of Medicine of the University of Edinburgh lends interest to the early history and development of a still older foundation of surgery in that city. The Royal College of Surgeons of Edinburgh has been a corporate body since on July 1st, 1505, the town council issued a decree formally uniting the Barbers and the Surgeons and constituting them one of the Crafts of the Burgh. In a chapter dealing with early records of the Craft, Mr. C. H. Creswell[1] has collected a quantity of most interesting information. In 1567 Queen Mary granted the Craft a Letter of Exemption by which members of the Craft were freed from the duty of bearing arms "provided that they be present with our armies ready to do their cure and duty to all such persons as shall have want thereof." It is pleasing to note that the Craft were as jealous or even more so of their privileges as any Trade Union of to-day. For instance, about 1635 two of the official "visitors" caught a surgeon who did not belong to the Craft—i.e., a non-union man, by name George Bell, and accused him of breaking their statutes by "laying a shearcloth about the laird of Fedderat." A shearcloth, we may explain, alias cerecloth, is a waxed sheet used for the preserving or embalming of a dead body. The contumacious George Bell confessed not alone to wrapping the body in the shearcloth but also to having made it, to having brought it to the house, and also to having embalmed the body. However, on promising never to do it again he was discharged. The Craft was also down on "covering," for in 1670 there was a member, one David Pringle, who was Apothecary and Surgeon Barber to the Heriot Hospital. About 7 A.M. on a certain day he was suddenly ordered to cut the hair of all the boys in the hospital, some 60 in number, in order that they might appear tidy before the magistrates. Being pressed for time Pringle sent a boy for another barber, who duly arrived but who was not licensed to practise in Edinburgh. His name was Wood, and at the instance of the Deacon of the Craft—i.e., the President—he was lodged in the Tolbooth, while Pringle was summoned before the Craft and eventually the case came before the Privy Council, and in the end Pringle acknowledged his error and was duly restored to all his former privileges. An interesting point which is found here and there throughout the book is the apparently high prices ruling; for instance, in 1647 the Craft took a house in which to hold their meetings in Dickson's Close and various furniture was provided, among the items being "a green table cloth" which cost £30 and "half a dozen of chares" £36. Some 70 years later—namely, in 1718—when the title of the Incorporated Surgeons had become

---

[1] Journal Path. and Bact., 1926, xxix., 189.

[1] The Royal College of Surgeons of Edinburgh: Historical Notes from 1505 to 1925. By Clarendon Hyde Creswell, late officer and sub-librarian of the College. Privately printed for the College by Oliver and Boyd, Edinburgh and London. 1926. Pp. 315. 10s.

"Royal College of Surgeons," Alexander Monro gave some anatomical preparations to the College and that august body apparently celebrated the occasion by a banquet, for a receipted bill for 38 pounds Scots bearing the same date as the gift of the preparations containing the following items: "To Charles Hay for a Chicken Pye £7 18s., and for Ale Brandy and Cheese £3 15s." The size of the Pye is not stated. We do not know, moreover, what the value of the "pound Scots" was in 1718, but as in 1600 it was only 1s. 8*d*., the table cloth, the "chares," and the Pye may not have been such extravagant luxuries as they seem, nor yet the half-gallon of ale "which you ordered the Lads" mentioned on p. 53 and costing 8*s*. The author deals with the further history of the College and its connexion with the Infirmary in an interesting way. A prefatory note to the book tells us that it was uncompleted at the time of Mr. Creswell's death on active service in October, 1918, and the work was edited and completed from material already collected by Mr. Creswell by two writers whose initials are given as A. M., and A. L. T. They seem to have done their work admirably except in one respect. The manner in which Latin inscriptions and phrases are printed does them no credit. Thus, on p. 104 the phrase "ad futuram re memoriam" should obviously read "ad . . . rei memoriam," and on p. 103 is an inscription from a piece of plate given to Mr. Thomas Hay which as given will make that eminent Scots latinist, George Buchanan, turn in his grave. The word "Viro" appears as "Nero," "viduis" appears as "vidius," and what should be "Vas hoce" appears as "Nas houe." Mr. Thomas Hay, we may add, received the piece of plate for his services in regard to the Widows' Fund of the College, an admirable pensions scheme which the various medical bodies in this country might well follow.

## OPEN-AIR SCHOOLS.

IN this country, where our cities are robbed of much of the sunlight by smoke, progressive educational authorities seek to get as much fresh air and sunlight as possible for school-children and especially for those with physical defects. In New Zealand, however, the problems of climate and sunlight have scarcely to be faced, with the unfortunate result that the scheme for open-air schools in that country, of which mention has already been made in this column,[1] is opposed by a certain amount of deep-rooted prejudice. To combat this an Open-Air Schools League has been instituted with the object of forming such a body of public opinion that the way will be made easy for the authorities to adopt the open-air school as a standard for schools throughout the country. With this end in view the League has started the publication of a small quarterly journal entitled the *Open-air Life*, and it has issued a second edition of a pamphlet reprinted from the *Christchurch Press*, wherein the case for the open-air school is emphatically urged.[2] The League has the backing of the medical profession, for in 1923 the New Zealand branch of the British Medical Association passed a unanimous resolution "that the educational authorities be urged to take into consideration the desirability of open-air schools when framing their school building proposals in the future." The Minister of Education, Sir James Parr, a patron of the League, has recently closely investigated the working of four open-air class-rooms, and as a result of this inquiry he is "to request the education boards of the Dominion generally to erect in suitable localities, in place of ordinary class-rooms, open-air class-rooms." The Open-Air Schools League starts with many advantages, and its publications should do much to purge school committees and boards of their old-fashioned preference for the solid school building and of their suspicion of the "draught" of fresh air.

## "NON-FREEZING" GAS.

THE annoyance caused by freezing at the outlet of a gas cylinder has become of considerable moment since the use of nitrous oxide and oxygen in major surgery became common. This freezing occurs owing to the fact that nitrous oxide gas becomes solidified into a sort of firm snow if exposed to a temperature as low as about −99° C. This low temperature is achieved when the liquid nitrous oxide of a cylinder escapes in gaseous form through the small outlet of the cylinder for a considerable time. Then to the snow of the gas itself is added ice which is formed from the freezing of water vapour in the atmosphere by the very extreme cold in the neighbourhood of the outlet of the cylinder. In order to obviate this process, resulting inevitably from conversion of the compressed liquid nitrous oxide into its gaseous form, it has been usual to employ some sort of small lamp to heat the outlet of the cylinder. The freezing which we have described takes place much less readily when the cylinder is used in the vertical than when it is used in the horizontal position, but even with the vertical position solidification at the outlet of the cylinder is an obstacle which has to be guarded against. In an improved form of apparatus described on p. 1044 of THE LANCET of May 29th, no provision is made for warming the cylinder's outlet, and it is expressly stated that a lamp is no longer needed if Messrs. Coxeter's "non-freezing" gas is used. This term is not literally correct, for nothing can prevent the freezing of nitrous oxide if it is exposed to sufficiently low a temperature. What Messrs. Coxeter have done, however, is to dry their nitrous oxide and the interior of their cylinders by special processes and thus to exclude as far as possible the presence of freezable water vapour with the issuing gas. Consequently the actual freezing at the outlet of the cylinder becomes much less common. Any step is welcome which reduces the complexity of anæsthetic apparatus, even if it is only the removal of a lamp. The chief drawback to modern methods of anæsthesia appears to us to be the introduction of involved apparatus. This leads to too great attention being paid to mechanisms and too little to the human body. The first requisite of a good anæsthetist is that he shall have constant recognition of the condition of his patient. The student of anæsthetics to day is rather apt to have his attention distracted from this essential matter while he attends to the proper working of tubes and air-ways.

## HOUSING AND HYGIENE.

THE influence exerted upon the health of the people by housing has often been claimed and less often demonstrated, a point to which we recently drew attention.[1] The fact that those who live in slums are unhealthy has been demonstrated beyond contradiction, but the problem is to discover whether the poverty-stricken and broken-down failures of life gravitate to the slums, or whether dwelling in slums causes breakdown in health. In the years immediately following the war, when shortage of houses was acute and overcrowding was extreme, mortality-rates fell, particularly for tuberculosis, and fell below those of the pre-war period; but at that time food-supplies had again become adequate, and the value of real wages was high. In other words, this evidence pointed to an inadequate food-supply, which is normally associated with poverty, as being a more powerful influence in causing mortality than slum environment. Dr. A. K. Chalmers, using figures for 1921–23, has recently approached the subject,[2] upon which he is an authority, from another aspect; he takes Scotland as possessing a larger proportion of tenement dwellings than England, where even Manchester has been described as a city of cottages of four, five, or more rooms. One point distinguishes the two types of dwelling; the cottage type is open to freely moving external air; in the tenement type, air enters from an unventilated common stairway or close. He finds here a possible reason why in Scotland mortality for each of the three groups of infectious diseases of infancy and childhood exceeds that of England. On the other hand, for certain diseases which are not air-borne—e.g., diseases of the circulation and cirrhosis of the liver—the mortality of England exceeds that of Scotland, from which the deduction may be drawn that the English population is not innately more healthy than the Scottish. Nephritis is more prevalent in Scotland, possibly a late result of a higher incidence of scarlet fever in childhood. Cirrhosis of the liver, usually accepted as an index of chronic alcoholism, is more prevalent in England. The position, then, as Dr. Chalmers presents it, is that lack of free uncontaminated ventilation—such as is exemplified by the tenement housing system of Scotland—is associated with greater mortality from infectious diseases. The factors concerned in housing are manifold, but something is gained from light thrown on how to build. Better houses attract better tenants and in time raise the social status and morality of the community; but the word "better" should, on the evidence now presented, mean dwellings with free access to outside air—apart from all other considerations. Hence a country cottage should be preferable to the London flat. Nevertheless, housing alone cannot determine the health and welfare of a community; economics are probably more powerful. A self-respecting population can make even wretched dwellings reasonably habitable—the condemned system of back-to-back houses has much in common with the arrangement of West-end flats. The inhabitants are at least as important as the accommodation they inhabit, and a degenerate population can convert the best accommodation into hopeless slums; even palaces, in times of revolution, have become pigstyes. When bad housing, as is usual, is occupied by bad tenants, the circle is vicious, each accentuating the influence of the other.

PENALTIES FOR FALSE STATEMENTS.—The Registrar-General has issued a memorandum drawing the attention of the public to the new penalties attached by Section 28 of the Criminal Justice Act, 1925, to false statements in connexion with marriages and the registration of births and deaths. The section came into force on June 1st, and the maximum penalty on conviction by summary process of giving false information for insertion in a birth or death register has been increased from £10 to £50; the time within which a prosecution can be undertaken has been extended to 12 months.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Wednesday, June 9th, at 3.30 P.M., Mr. Zachary Cope will give a special demonstration in surgery at St. Mary's Hospital, Paddington, and on Thursday, June 10th, Mr. Whiting will give a special demonstration in ophthalmology at the Royal London Ophthalmic Hospital, City-road, at 12.45 P.M. These demonstrations are open to all members of the medical profession without fee. The Chelsea Hospital for Women provides a two weeks' course from Wednesday, June 9th. There will be a course in genito-urinary diseases at the All Saints' Hospital from June 7th to July 3rd. From June 14th to 26th the City of London Hospital for Diseases of the Heart and Lungs will give a special course; demonstrations and lectures will be given in the various departments of the hospital, the whole of which is thrown open to post-graduates during the course. There will be a course, primarily for general practitioners, at the London Temperance Hospital from June 14th to 25th daily from 4.30 to 6 P.M. Courses will be held during July in cardiology, at the National Hospital for Diseases of the Heart; in dermatology, at the Blackfriars Skin Hospital; in neurology, at the West End Hospital for Nervous Diseases; and in ophthalmology, at the Royal Eye Hospital. There will also be an intensive course in medicine, surgery, and the specialties at the North-East London Post-Graduate College (Prince of Wales's General Hospital), Tottenham, N. Copies of all syllabuses, of the General Course programme, and of the *Post-Graduate Medical Journal* may be had on application to the Secretary of the Fellowship at 1, Wimpole-street, London, W.1.

# Modern Technique in Treatment.

*A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.*

## CLXXV.—TREATMENT OF CONGENITAL SYPHILIS IN CHILDREN.

THE principles of the treatment of congenital or of acquired syphilis in adults and children are substantially the same. While conceding that the older methods of treatment with mercury and iodides may have cured or greatly benefited a considerable percentage of cases of congenital as well as of acquired syphilis, most authorities to-day are of opinion that better results are obtained in all forms of the disease by combined therapy with arsenicals and mercury or bismuth. In practice, however, it is found that in many cases of congenital syphilis the beneficial results of the treatment are not so quickly observed as in recent cases of the acquired disease. The reason for this is obvious when one remembers that in the congenital disease (1) the spirochæte is often widely spread throughout the patient's body; (2) it may have been there from quite an early period of intra-uterine life; and (3) the spirochæte or its toxins may have produced more or less serious pathological changes in the tissues and organs of its victim.

*Diagnosis.*—Before condemning a child to a course of treatment which may extend over many months or even years, one should be reasonably certain of the diagnosis. The clinical diagnosis should, if possible, be confirmed by the Wassermann test, even when the case is obviously syphilitic, in order to control the duration of the treatment. The diagnosis established, treatment should be started forthwith.

### *Combined Arsenical Therapy.*

*Arsenic Preparations.*—One of the salvarsan preparations, together with mercury or bismuth, may be used. Preparations of the original salvarsan (606) type are not very applicable to children, so that the preparations which can be given in concentrated form are now generally employed. Among these may be mentioned novarsenobillon (N.A.B.), neokharsivan, neo-silver-salvarsan, sulfoxyl-salvarsan, stabilarsan, and sulfarsenol. The drugs most used in children's clinics are N.A.B. and sulfarsenol as they are the least toxic and quite efficacious. The other drugs are more likely to produce vaso-motor and other disturbances, such as vomiting, shivering, fever, and albuminuria.

The dose of the drug depends upon the size of the child; the initial dose of N.A.B. would be 0·05 g. for an infant a month old, 0·1 g. for a child 1–3 years, 0·15 g. for older children. During the course of six injections the amounts injected will increase respectively from 0·05 to 0·1 g., from 0·1 to 0·25 g., and from 0·15 to 0·3 or 0·45 g. The subsequent courses of injections will start with rather larger doses than the first and attain high maxima, but a dose of 0·45 g. N.A.B. should never be exceeded in a child of 12 years of age. The corresponding doses of sulfarsenol would be 1½ cg. for an infant a month old, increasing to a dose of 8 or 12 cg. at the end of the first course. For older children commencing doses may be 4 or 6 cg., working up to a maxima of 24, 30, or 36 cg. according to the age and size of the child. Even in older children it is advisable to start with a small initial dose, such as 0·1 g. N.A.B. or 6 cg. sulfarsenol, in order to test the patient's tolerance for arsenic.

*Mode of Administration.*—The drug is dissolved, immediately before it is required for the injection, in a small quantity of freshly distilled, recently sterilised water. The smaller doses do not require more than 1 c.cm. of water to dissolve them; for the larger doses 2 to 3 c.cm. are necessary. N.A.B. may be administered intramuscularly or intravenously; sulfarsenol, subcutaneously or intramuscularly. Intramuscular injections are usually made into the buttock, and in order to avoid the large vessels and nerves in this region, one selects a point above the horizontal line joining the anterior superior iliac spine and the top of the natal cleft. The point of injection should be somewhere along the middle third of this horizontal line. Before injection the part is sterilised with iodine, and after injection the puncture is sealed with collodion. Provided the injection of N.A.B. goes deeply into the muscles, this method is practically painless and is followed by no ill-effects. On the other hand, if the injection is too superficially made, it may be followed by considerable swelling, pain, and even necrosis. In order to obviate these possible accidents, the drug sulfarsenol was introduced for intramuscular and subcutaneous injections, and this drug is, perhaps, more largely used than any other at the present time for the treatment of congenital syphilis in infants, in whom intravenous injections are difficult to carry out. Subcutaneous injections of sulfarsenol may be made in the buttock, between the scapulæ, or into the abdominal wall.

When possible the injections of N.A.B. are given intravenously and preferably into a vein at the bend of the elbow. Some authorities use the external jugular or scalp veins for injections in infants, but unless the operator is experienced and skilled assistance is available, injections into these veins are not easy to carry out. I do not consider that it is justifiable to inject these drugs into the superior longitudinal sinus or to cut down to expose a vein for the purpose of injection. In older children if the injections cannot easily be made into a vein at the elbow, the N.A.B. should be given intramuscularly, as in infants, or sulfarsenol may be given subcutaneously or intramuscularly. For these injections the three-piece all-glass syringes supplied by Burroughs, Wellcome and Co. are the best I have come across. These syringes are also the best for taking blood from children for the Wassermann test.

*Mercury.*—As already indicated, reliance should not be placed solely upon the arsenic preparations, but mercury or bismuth should be used in addition. Mercury is given either in the form of hyd. cum cret., gr. ½ to 1, three times a day, or, better still, the ointment may be rubbed in once a day or pills of green iodide of mercury, gr. ⅙ to ¼, two or three times a day administered during the injections.

*Bismuth.*—During the last few years various preparations of bismuth have given most encouraging results; at the present time a considerable number of syphilitic patients are being treated with bismuth alone. Bismuth compounds in use include: (1) metallic bismuth in fine suspension, known commercially under the names neo-trepol, bismuthyl, bismostab, bismuth metal, &c.; (2) oily suspensions of bismuth salts, amongst which are trepol, muthanol, and luatol; and (3) a compound of bismuth and arsenic recently introduced by Levaditi, marketed under the name of bistovol. This, too, is an oily suspension for intramuscular injection, which should prove to be a valuable addition to our antisyphilitic remedies. A course of bismuth usually consists of 10 or 12 injections given once or twice a week, after which there is a month's rest.

*Salvarsanised Serum.*—Intrathecal injections of salvarsanised serum may be made with benefit to the patient, either in the lumbar region or into the cisterna magna, in cases of cerebro-spinal syphilis with a positive W.R. in the cerebro-spinal fluid This treatment may also be tried, either alone or after a malarial infection, in cases of juvenile general paralysis. Intravenous injections of N.A.B. would be given at the same time.

### *Duration of Treatment.—Results.*

In a disease like congenital syphilis it is well-nigh impossible to be certain that the disease has been eradicated. The aim of treatment should be (1) to cure the clinical manifestations of the disease for which the patient seeks advice; (2) to prevent their recurrence, and also, if possible, the appearance of other symptoms of congenital syphilis; (3) to render the blood W.R. negative, and to keep it negative if possible. A single course of arsenic injections with mercury or bismuth may clear up the patient's symptoms and even render the W.R. negative in a very young patient, but it is inadvisable to cease treatment at this stage. At least one course of combined treatment should be given after the W.R. has become negative, and thereafter mercury for one or two months or a course of bismuth each year should be given for a year or two, the blood being tested every three to six months. Should the reaction become positive again, more energetic treatment must be instituted. When children do not come for treatment until they are several years old, it may be necessary to give 30 to 40 or even more injections of arsenic before the W.R. becomes negative, and sometimes it may be impossible to get it negative even after 50 injections. Cases of cerebro-spinal syphilis with a positive W.R. in the cerebro-spinal fluid, and those with laryngeal and naso-pharyngeal ulceration are most refractory.

Epiphysitis and enlarged joints, interstitial keratitis, &c., should be treated on ordinary surgical lines; condylomata and mucous tubercles should be dusted with calomel powder. During the intervals between the courses of injections tonics may be advisable, such as malt and cod-liver oil, syrup ferri phos., or syrup ferri iodidi. General dietetic and hygienic details should also receive attention.

There are two groups of cases about which an opinion may be asked: (1) children who have positive W.R. but show no symptoms or signs of the disease; and (2) children, in syphilitic families but with negative W.R., who suffer from such vague conditions as malnutrition, debility, and so on. I think both these groups of cases should receive treatment, the former in order to prevent a possible development later on of such manifestations of syphilis as interstitial keratitis and other symptoms, which may not appear till puberty or even later. The latter group should be treated because the family syphilitic taint may be present, and good results have followed such treatment.

A very large proportion of children treated by the method show improvement, sometimes even after the first course of injections. Others may take longer, but in most cases the beneficial results are obvious; specific ulceration quickly heals, hæmoglobinuria ceases, fits become fewer in number or may be entirely stopped. Even mentally defective patients may show a considerable degree of improvement in their condition. Interstitial keratitis responds well to treatment, and if this is started early in the disease the inflammation clears up entirely, no opacity of the corneæ persisting in after life. Nevertheless, in spite of the latest forms of treatment, a considerable proportion of very young children succumb to the disease.

### *Toxic Manifestations.—Prophylaxis.*

On the whole, children are very tolerant to arsenic, but occasionally toxic symptoms of varying degrees of severity may be manifested. The commonest of these is vomiting; others are shivering, cyanosis, swelling of the face and limbs, diarrhœa, and rarely coma; albuminuria may also be produced. In prolonged treatment particular attention should be paid to rashes and incipient jaundice. When the vaso-motor toxic manifestations occur with each injection, sodium thiosulphate (g. 0·45) may be injected intravenously with each dose of N.A.B., but when jaundice or an arsenical rash threatens, the injections of arsenic should cease for a time and a daily injection of sodium thiosulphate be substituted.

When bismuth injections are being given, particular attention should be paid to the teeth and gums, and a mouth wash of peroxide of hydrogen recommended. The urine should be tested from time to time for the presence of albumin, and if this condition or a bismuth line on the gums should be present, treatment should be suspended for a time.

It has been known for a considerable time that if a syphilitic mother be treated during the course of a pregnancy with mercury, or preferably by injections of arsenic or bismuth, the child born after such treatment will be free from any syphilitic taint, and that it will probably remain healthy. This being so, it is the obvious duty of all practitioners to advise a syphilitic prospective mother to undergo treatment. For, although a case of congenital syphilis which is diagnosed early and properly treated may ultimately be cured, the child has to make a large number of visits to the hospital or doctor and must of necessity be pricked a large number of times; both of these factors may produce serious psychological effects.

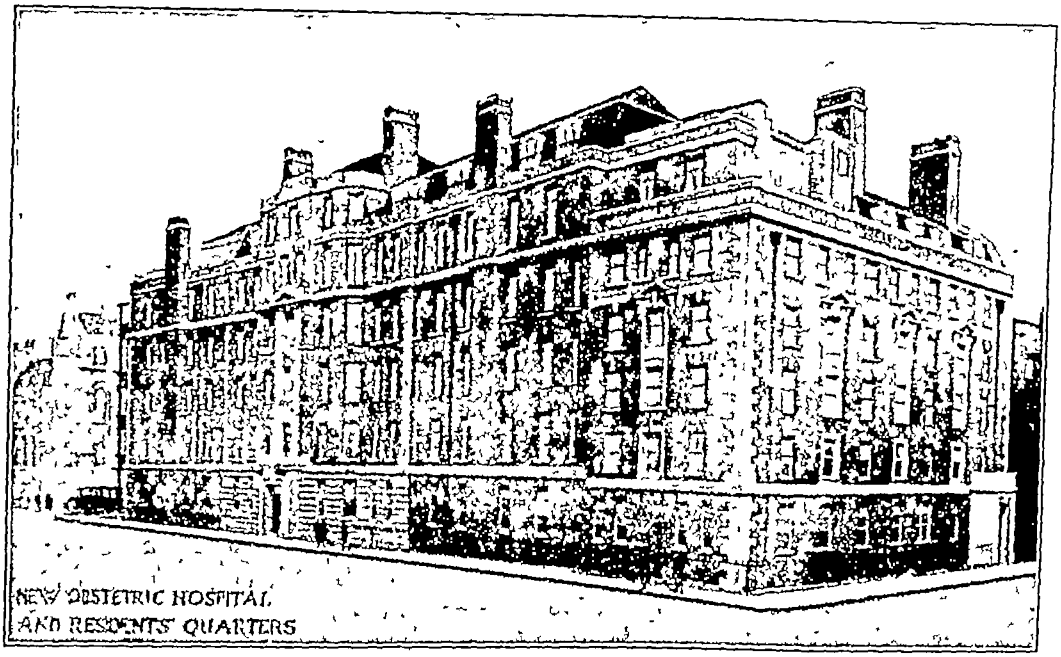
## ENLARGEMENT OF UNIVERSITY COLLEGE HOSPITAL.

### THE ROCKEFELLER GIFT.

ON the afternoon of May 28th the Prince of Wales visited University College Hospital and formally opened the new buildings whose foundation-stones were laid by the King and Queen just three years ago. The Maternity Hospital and Nurses' Home which now come into use are part of the Rockefeller Foundation's gift to this country for the advancement of medical science and education. It will be remembered that in 1920 the Foundation's trustees selected University College Hospital for a grant, and that £1,205,000 was given to the Medical School and College. This sum was allocated as follows: £435,000 as an endowment fund for medical research and education; £400,000 for the provision of 180 additional beds, including a new obstetric and gynæcological hospital; £370,000 for an institute of anatomy, and for an endowment fund for the maintenance of buildings and staffs. The donation was made without conditions and was so large as to allow the hospital authorities a free hand in the development of their work. It was made, however, in the interest of medical progress in general rather than for the benefit of a particular section of a particular community, so the Foundation considered that the sum needed to endow the beds of the new obstetric hospital should be collected in the British Empire and should not form part of an American gift. The success of the appeal launched by University College Hospital has already been recorded in our columns [1]; the 60 beds are now fully endowed with a capital sum of £180,000.



The new obstetric and gynæcological hospital, which is here illustrated, has been erected on the west side of Huntley-street and forms an annexe to University College Hospital. There are 30 gynæcological and 30 obstetric beds. Accommodation is provided on the premises for maternity students on duty and a senior member of the medical staff is to be in residence so as to undertake the management of complicated cases and give instruction in midwifery. There are already units of medicine and surgery at the medical school and the Unit of Obstetric Medicine, under the direction of Prof. F. J. Browne, will be the third and last of the teaching units. The out-patient maternity department will work in with the new hospital.

One hundred new beds have been added to the 300 in the main building by converting the nurses' quarters into wards, and this has made it necessary to find other accommodation for the nurses. An increase in the size of the hospital has involved an increase in the size of the staff, and the new Nurses' Home provides for about 250 nurses. The Home is a continuation of the Trained Nurses' Institute in Huntley-street, and those who live in it will be fortunate in their surroundings.

The Rockefeller Foundation's grant has already attracted other benefactions to University College Hospital, and the Prince of Wales completed his visit by unveiling a memorial tablet at the new Royal Ear Hospital, built by Lieut.-Commander Geoffrey Duveen in memory of his father and mother, Mr. and Mrs. H. J. Duveen. This hospital was previously situated in Dean-street, Soho, but the new building is at the junction of Huntley-street and Pancras-street beside the obstetric hospital, and thus forms part of the University College group. Lieut.-Commander Duveen attended the ceremony in May, 1923, when the King and Queen inaugurated the new extensions, and he was so impressed with the possibilities opened up by the help of Rockefeller Foundation that he gave £15,000 for the purchase of a site and £50,000 for the re-erection of the Ear Hospital in proximity to the other buildings. The hospital is now nearly complete, and will have three wards (each containing ten beds) for ordinary patients, and eight single-bedded wards for paying patients. There will also be ample accommodation for out-patients and a silence room with a capacity of nearly 3500 cubic feet which is designed to ensure accuracy in the examination of the deaf.

It was announced that the sum of £10,000 had already been given to the hospital in connexion with the appeal shortly to be issue on behalf of the General Maintenance Fund, and it was later revealed that the donor was Major Harold Wernher, chairman of the hospital Finance Committee.

The Prince of Wales was warmly received by a large gathering of guests and students. The American Ambassador was, unfortunately, prevented from attending, but was represented at the ceremony.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

### *The Free State Medical Register.*

THE announcement made last week in the Irish press that an agreement had been reached between the Irish Government and the medical profession appears to have been in advance of the facts. A conference took place on May 26th between members of the Government and representatives of the medical profession, and the latter were made acquainted with the rough outlines of the legislation that the Government had in view. A further meeting was arranged for June 9th, and in the meantime all discussions that take place are confidential. The more or less intelligent anticipations of the Government proposals in the daily press need not, therefore, be regarded very seriously. It is stated in the newspapers, however, that immediate legislation is not intended, and that definite proposals will not be put before the Dail until the autumn. Nevertheless, it is likely that President Cosgrave will make a statement before the adjournment.

### *Annual Report on Mental Hospitals.*

The annual report of the Inspector of Mental Hospitals for 1024 has recently been issued. It is stated that the number of insane patients under care on Dec. 31st, 1924, was 19,381, being more by 138 than at the end of the previous year. Of the total number 84·1 per cent. were in district mental hospitals, 5 3 per cent. in private mental hospitals or in single care, 10 per cent. in Poor-law institutions, and 0 6 per cent. in the State Criminal Lunatic Asylum. At the end of 1924 the number under care in district hospitals was less by 659 than at the end of 1915. From 1915 to 1920 there was a steady fall in the asylum population, but since 1921 there has been a steady rise The number of first admissions in 1924 was 2100, which is equivalent to 66 per 100,000 of the estimated population, and there were 584 readmissions. The number discharged in the year was 1350, of whom 959 were discharged recovered. The number of deaths was 1092. The disease responsible for the highest proportion of deaths was pulmonary tuberculosis, with 211 deaths; the next highest cause being organic disease of the heart, which was responsible for 188 The Inspector comments favourably on the management of most of the asylums.

### *The Montgomery Lecture in Ophthalmology*

The Mary Louisa Prentice Montgomery Lecture in Ophthalmology was delivered in the Royal College of Surgeons on May 28th by Mr. Charles B. Goulden, ophthalmic surgeon to the London Hospital. Mr Goulden chose as his subject Accommodation, and he gave an interesting sketch of the history of the knowledge of the subject down to the present day, illustrating his lecture with lantern slides.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### *Statistics of Vaccination.*

THE Prussian Health Department has published a report on the results of vaccination in 1924. The number of vaccinations done was 1,027,695, and of revaccinations 880,186. In 7 per cent. of the children vaccination was postponed because of ill-health, and revaccination had to be postponed in 0 8 per cent. on the same account. Nine deaths were recorded amongst the vaccinated children; these included a case of pneumonia, two cases of gastro-intestinal catarrh, and two cases of convulsions, in one of which vaccination was negative. None of these can be ascribed to vaccination. In one case a child died from bronchitis, having obviously caught cold at the time of the vaccination. In two cases death occurred from septicæmia; in both of these the disease developed late, after the medical man had given the certificate. These last two cases may be regarded as connected with vaccination, but the immense number of vaccinations performed must be remembered. Other undesirable complications were: severe inflammation of the surrounding tissues, swelling of the lymphatic glands, cellulitis, erysipelas, gangrene of the pustule, chronic exanthem, and (in two cases) generalised vaccinia. Vaccination pustule developed by contagion in the family of the vaccinated child in 12 cases. In no case did syphilitic infection result from vaccination. Parents held back their children from vaccination in 52,699 cases (5 8 per cent. of the children subject to compulsory vaccination) and from revaccination in 9004 cases (1 1 per cent. of refusals). The number has increased since the preceding year, when only 3 75 and 0 8 per cent. respectively were held back. The opposition against vaccination is still growing, but there are remarkable variations in the different Government districts. In Hanover the number of children who did not attend was 18 per cent.; in Stettin it was only 1 1 per cent. The report gives some interesting local details. In one town in the Magdeburg district opponents of vaccination tried to hinder the public vaccinator in the performance of his duty and were accordingly prosecuted; in another town it was observed that mothers wiped away the vaccine immediately after vaccination. Sometimes the public vaccinators were requested to bind themselves to make good any damage caused by their treatment. All these troubles were obviously due to a systematic campaign arranged by the antivaccinationist association. Although many parents had to be fined there were only a few instances in which it was necessary for the police to bring the child to the public vaccinator.

### *The German Congress of Radiology.*

The annual congress of the German Radiological Society was recently held in Berlin and well attended by German radiologists and foreign guests, including Dr. A E. Barclay, of Manchester, and Prof. L. H. Edling, of Lund, Sweden. The chair was taken by Prof. Martin Haudek, of Vienna. Dr. O. Jüngling, of Tubingen, read a paper on the prophylactic application of X rays in cancer of the breast. He said that the value of the different methods of applying X rays in cancer could only be ascertained when the statistical records were drawn up on a uniform plan. The results obtained at the individual clinics still differed greatly. For the most part the application of rays in large doses had been given up, the more frequent administration of medium doses being now preferred. Dr. Holfeld, of Frankfurt, said that in recurrence of growths large doses given within a short interval gave good results, but in cases where recurrence was only potential small doses applied over a longer period were better. Dr. Wieser, of Vienna, spoke on the radiological treatment of mental and nervous diseases in children. Idiotic children, he said, could be improved so much that they became able to attend a special school. Mongols, who, as a rule, learn to speak only at the age of 7 to 8 years, could be made to speak three or four months after the administration of the rays. Endocrine secretion was obviously improved by the rays; the Abderhalden reaction enabled the physician to ascertain which of the glands was affected and the rays were applied accordingly, either to the thyroid, the sexual glands, or the brain. Dr. Straus, of Berlin, read a paper on the radiographic examination of the gall-bladder which, he said, had hitherto not been very successful. The method of administering tetriodphenolphthalein, as recommended by the American physician, Dr. E. A. Graham, had, however, proved very valuable. The compound is discharged into the gall-bladder, and a reliable figure of this organ is seen on radiographic examination in 80 per cent. of cases. Dr. Pribram, of Berlin, said that he preferred intravenous injections of the drug; the pain produced was less and the appearance of the gall bladder was more distinct. Dr. Holthusen reported on the standard measurement of P doses; it is based on the ionisation of the air by the rays. The standard unit is to be called a Rontgen and designated by "R." Dr. R. Glocker, of Stuttgart, reported on international regulations to protect medical men, their assistants, and their patients against the dangerous properties of X rays.

### *Cardiac Complications of Tropical Diseases.*

Prof. M. Couto, of the University of Rio de Janeiro, who lately visited Berlin, read a paper before the Berlin Society for Internal Medicine on Cardiac Troubles in Tropical Diseases. Cardiac symptoms, he said, were often in the foreground in beri-beri, malaria, Chagas's disease, and yellow fever. In beri-beri the first symptom was often tachycardia, followed by angina pectoris and respiratory troubles. These symptoms were due not to affection of the cardiac nerves, but to myocarditis. Prof. Couto has detected the presence of parasites in the coronary arteries and a fatty degeneration of the myocardium. In ankylostomiasis, he said, severe anæmia was caused by intestinal hæmorrhage, the virus hindering the coagulation of the blood. Systolic murmurs were therefore audible in all the cardiac areas and over the jugular vein. In Chagas's disease not only the valves, but also the myocardium were penetrated by cultures of parasites. Yellow fever, which, he said, had now entirely disappeared in Brazil, produced degeneration of the heart muscle.

### *Cure of Paralysis of Intestines.*

Prof. Rosenstein lately reported before the Berlin Surgical Society on the results he has had in the treatment of intestinal paralysis by injections of a nicotine solution into the cœliac ganglion. The injections were performed after the method devised by Kappis for the anæsthesia of the splanchnic nerve. After the injections had been successfully done in animals they were performed in six patients, the result being that the peristaltic movement at once began without any undesirable complication. The method is to be applied, of course, only in cases where other remedies have failed. In the majority of cases of intestinal paralysis hormonal is efficacious.

### *Pneumonia in Measles.*

In a paper recently read before the Berlin Pædiatric Society Dr. Henning stated that in some epidemics of measles the mortality from pneumonia reached 50 per cent. The organisms producing pneumonia were hæmolytic streptococci, which were present in the bronchial secretion of pneumonia patients. These streptococci were evidently responsible for the high mortality of pneumonia in measles, because in cases of pneumonia with measles in which hæmolytic streptococci were absent the mortality was only 15 per cent.

## VIENNA.

(FROM OUR OWN CORRESPONDENT.)

### *Infection of the Urinary Tract and its Treatment.*

AT a recent meeting of the Vienna Gesellschaft der Aerzte Dr. Sternbach discussed the new method of treating infectious conditions of the urinary system by compounds of the salvarsan group. After unsatisfactory trial of various preparations, he said, he had turned to spirocid, which is identical with the stovarsol of the French authors. This compound was discovered by Ehrlich in the course of his researches on salvarsan, but he discontinued its use because he found salvarsan more effective in the treatment of syphilis. During the war, however, Levaditi and Fourneau (Paris) took it up again as a prophylactic against syphilis. As this substance can be given by the mouth, Dr. Sternbach used it extensively, giving small doses—2–3 tablets of 0·25 g. (about 4 gr.)—daily. He cured a case of staphylococcic cystitis of five months' duration within five days, although it had resisted treatment with neosalvarsan and cylotropin, and he cured a case of gonococcal urethrocystitis in six days. Other cases of staphylococcal infection also reacted promptly to spirocid, but coli infections were refractory; in mixed infections the staphylococci were always destroyed. Dr. Sternbach feels justified in asserting that spirocid acts strongly against gonorrhœa and diminishes secretion. Post-gonorrhœal conditions are also greatly benefited and he has never seen any untoward effects when the preparation is given in small doses. In the discussion which followed Prof. M. Oppenheim, who was the first in Germany and Austria to use spirocid in the treatment of syphilis, stated that he had given it in 350 cases of lues where he could not use salvarsan and had had very good results without any unpleasant complications. Other physicians also said that they had seen good results from the use of this remedy in mild gonorrhœa, but considered that an extensive trial of the antigonococcal and antistaphylococcal factor was needed before a definite opinion could be given.

### *Impending Changes in the Medical Faculty.*

Within the next few weeks important decisions will have to be reached by the Board of Education of the Austrian Republic, for no less than four clinical chairs have to be filled. For more than a year there has been no professor of general and experimental pathology, and the leading members of the faculty are of opinion that such a chair, although a necessity some 30 or 40 years ago, is no longer absolutely essential. The students, it is thought, could use the time thus saved for the study of more important and practical subjects, such as dental surgery. There is another vacancy in the Second Ophthalmological Clinic, which has lost its chief by the death of Prof. F. Dimmer; probably his successor will be Prof. Max Salzmann, at present chief of the eye clinic of Graz. He was assistant to the celebrated Prof. Fuchs, and if he is appointed it will be a break in the custom of sending to Germany to find successors to celebrated professors. The two skin clinics will also require new chiefs, as Prof. G. Riehl and Prof. E. Finger will shortly resign on account of age. Prof. Riehl's clinic will probably be taken over by Prof. L. Arzt, now of Innsbruck; some of his competitors are hampered by their creed, for they are Jews, which makes it almost impossible for them to be appointed. As yet it is difficult to forecast who will take Prof. Finger's place, as it is most desirable that those who have to carry on the renowned Vienna school of dermatology should be first-class men.

### *Influx of Foreign Doctors to the University.*

The report of the Board of the University for the winter term again shows that the reputation of this ancient institution has not failed to regain its hold upon the medical men of the old and new world. Amongst the post-graduate students, enlisted for the last winter term—many of them have also enlisted for this summer term already—we find over 230 doctors from the United States and Latin America, 42 from Egypt, 16 from South Africa, 3 from India, and 29 from Japan and China. Of course, European doctors (Russia, Turkey, Rumania, and Poland) are also present in considerable numbers. There is no restriction of admission for foreign doctors as regards post-graduate work; but foreign medical students, who have not yet obtained their diploma, will find it somewhat difficult to gain admission, as the scarcity of dissecting material and laboratory accommodation makes it necessary to give preference in the fundamental teaching facilities to indigenous students, so as to ensure an adequate supply of Austrian doctors.

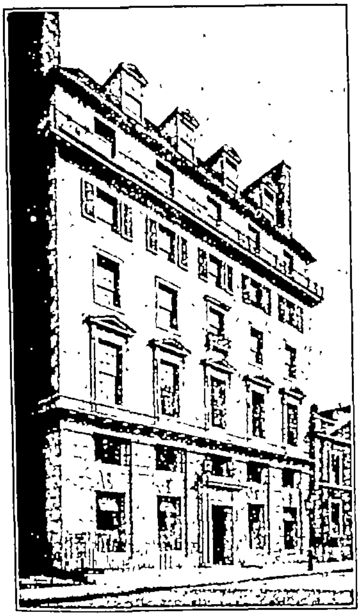
---

THE Minister of Health has approved the appointment of Mr. E. J. Maude to be Solicitor and Legal Adviser to the Ministry of Health, and of Mr. G. R. Hill to be an Assistant Solicitor. These arrangements take effect on the appointment of Mr. M. L. Gwyer, C.B., solicitor to the Ministry, as King's Proctor and Treasury Solicitor.

# THE COLLEGE OF NURSING.

## OPENING OF THE NEW BUILDING.

FIG. 1.



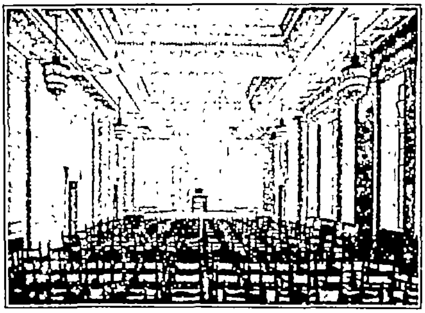
The College of Nursing: The Entrance Front to Henrietta-street.

THE new building, presented by Viscountess Cowdray to the Council of the College of Nursing, was opened on Monday, May 31st, by H.M. the Queen, who was received by Sir Arthur Stanley (chairman of the Council), the Mayor and Mayoress of St. Marylebone, Lady Cowdray, Dame Sarah Swift, R.R.C (President of the College), and Sir Edwin Cooper, the architect.

The building of the College proper gives on Henrietta-street, next door to the house of the Royal Society of Medicine, and is intimately connected behind with the Cowdray Club (entrance to Cavendish-square), a previous gift by the founder designed to further the social side of the College's work. On the ground floor the Nurses' Memorial and Lecture Hall, which occupies the entire width of the building, is, with its excellent acoustics, well adapted for post-graduate teaching. On the first floor the beautiful council room has a committee room on one side of it and on the other the Library with shelves for 5000 books and a replica in bronze of Walker's statue of Florence Nightingale. Above is a cookery demonstration room and a physiological laboratory to be used to instil the principles and methods of simple cookery and the nutritive values of foods into the minds of student-nurses; hospital training schools are invited to avail themselves of these courses. The equipment is completed by a comfortable common room for members and a sitting room for the Students' Association. In the basement a system of filing makes it possible to refer in a few moments to the dossier of any of the College's 25,000 members.

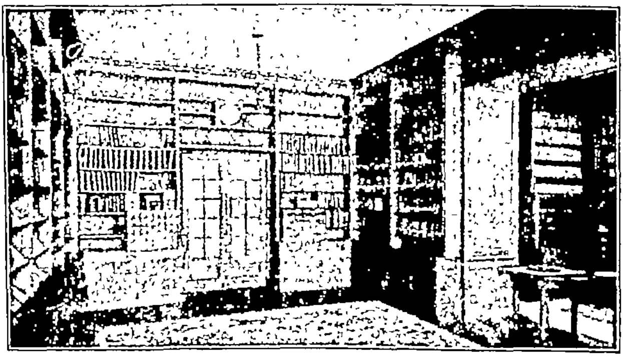
At the opening ceremony Sir Arthur Stanley made a statement on the history and aims of the College. It was in 1915 that he as chairman of the British Red Cross Society, in coöperation with Dame Sarah Swift (Matron-in-Chief B.R.C.S.), Miss Haughton (Matron of Guy's Hospital), and Sir Cooper Perry called upon leaders of the nursing profession to establish an organisation whose policy should be to unite all trained nurses in the endeavour (1) to provide a uniform standard of training, which should be a basis of membership of the College; (2) to improve the quality of the nursing service and the conditions under which nurses work; (3) to assist in securing State

FIG. 2.



The Memorial Hall.

FIG. 3.



The Library.

registration of nurses; (4) to further the advancement of the nursing profession through legislation, post-graduate study, scholarships, and specialised training. In the following year the College was incorporated under the Companies Acts as a company limited by guarantee and not having a share capital. Life membership was then granted for a single payment of £1 1*s.*; later many of the original members voluntarily undertook to pay a yearly subscription of 5*s.*, or a fee of £5, for which more recent members were admitted as life members. At the present time there is an entrance fee of £1 1*s.* and a yearly subscription of 5*s.* The Council of the College is elected by the members; at the present it consists of 27 women, most of them registered nurses, and eight medical men, with Sir Arthur Stanley as Chairman, Sir Cooper Perry as honorary secretary, and Dame Sarah Swift as President. There are now 41 local branches; the London centre, though housed in the College, is in the same position as any other branch, and pays rent to the College for its office accommodation.

One of the Council's first pieces of work was to draft a Bill in 1916 for the State registration of nurses. This Bill was not passed, but in 1919 a Government Bill, supported by the College, was introduced and became law. In 1917 was inaugurated the Nation's Fund for Nurses to endow the College and to provide a benevolent fund for the relief of nurses in sickness and distress. In 1919 a course of training for sister tutors was established in coöperation with King's College for Women. Scholarships for this course and for other courses in public health and midwifery have been granted to the value of over £4000. In 1920 a badge was issued for members of the College, and in that year a quarterly *Bulletin* began to appear. A scheme of grants for disabled nurses received the approval of the Ministry of Labour and gratuities were granted to the Royal Naval Nursing Service, through the intervention of the College. A loan fund was established to assist members professionally, and a rest cottage was opened for use of members and others at Bonchurch. In 1921 post-graduate courses were started in coöperation with Bedford College for Women and the League of Red Cross Societies. In this year exemption was obtained for nurses from the Unemployment Insurance Act, a scheme for accident and sick insurance was arranged, and the superannuation scheme was drawn up which is now being considered by the Hospitals' Association. In 1922 the Cowdray Club was presented to the College by Lady Cowdray and the foundation-stone of the College building laid, In 1923 the public health section of the College was formed and a library of nursing started, with help from the Carnegie U.K. Trust, the use of the library to be free to all nursing students. In 1925 a special department of education was set up to develop post-graduate study. The Ministry of Health recognised the College as an approved centre for the training of health visitors, with whole-time six-months' courses, and a three months' evening "refresher" course for practising health visitors. Free legal advice on professional matters is available for all members of the College, consultations being given by Mr. Archer Ryland, Mr. Cyril Nitch, and Dr. Maurice Cassidy.

The endowment fund of the College has now reached £68,700, mostly raised by nurses themselves, the contribution of the medical profession amounting to about £1000.

---

BARTLET CONVALESCENT HOME, FELIXSTOWE.—The late Dr. J. H. Bartlet, who practised for many years in Ipswich, as his father and grandfather had done before him, and died in 1917, left the residue of his estate, amounting, with accumulated interest, to £230,000, for the provision of a convalescent home appurtenant to the Ipswich and East Suffolk Hospital. The building, which has been in course of erection at Felixstowe for nearly three years, has now been opened by Sir Arthur Churchman, M.P. The cost has been £91,000, and the balance of about £1 10,000 is being invested as a maintenance fund. . The building has been partly erected upon the foundations of an old martello tower. It will accommodate 60 patients in four wards.

---

# GENERAL MEDICAL COUNCIL.

## PRESIDENT'S ADDRESS.

THE summer session of the General Medical Council was opened on June 1st, Sir DONALD MACALISTER presiding.

After mention of the effects of the strike and the difficulties attendant on travelling and printing which might hamper the Council in its work, the PRESIDENT referred to changes in the Council's personnel since the last session. He spoke warmly of the services of Dr. Richard Caton who for 22 years had represented the University of Liverpool and who died on Jan. 2nd. "Honoured and admired at home and abroad for his civic and academic services, his erudition, and his professional gifts, he was beloved for his sterling goodness and his genial humanity. To his friends, his approval was a thing to be prized; to those who knew only of his labours, his example was a thing to be followed." In succession to Dr. Caton the University of Liverpool had appointed Mr. William Thelwall Thomas, F.R.C.S., whose record assured the Council that it might count on its receiving from him contributions of value to the common good.

The President next paid a tribute to the work of Sir Francis Champneys, who had resigned at the close of the third period of five years for which he had been appointed by the Crown. The Council, he said, had always had important duties to perform in respect of midwifery in the medical curriculum, and during the last 20 years new duties had been added by successive Midwives Acts for England, Scotland, and Ireland. In fulfilling these functions it had been constantly indebted to Sir Francis Champneys for wise and well-informed counsel. His comprehensive knowledge of administrative, educational, and professional conditions, and his experience as chairman of the Central Midwives Board for England, had made his original appointment by the Crown especially welcome and opportune, and his helpfulness to the Council had earned for him its abiding gratitude. Sir John Williams, the immediate predecessor of Sir Francis Champneys as a Crown member, had died a week ago full of years and honours, and in him the University College and the National Library of Wales had lost a distinguished president and a generous benefactor.

A further vacancy had been caused, said the President, by the resignation of Sir Gilbert Barling, Vice-Chancellor of the University of Birmingham, whose loss was the more regrettable because the ground of his withdrawal was impaired health and the urgent need of rest. During the nine years of his membership Sir Gilbert Barling had shown the qualities that had won him high repute in Birmingham and its university as an active promoter and constructive critic of educational progress, and the Council cordially wished him better health and a speedy restoration to active life.

After a reference to the honour of knighthood bestowed on Dr. Robert Bolam, the President continued as follows:—

### *Vacant Seats on the Council.*

"At the time of writing this address I had received no formal intimation of a successor to Sir Gilbert Barling. The intimation may or may not reach us during the session. I gather, on the other hand, that it is highly probable that to-day His Majesty in Council may signify his pleasure respecting a successor to Sir Francis Champneys. To the two new members, when they are appointed, the Council will, I know, empower me to offer the assurance of a fraternal welcome to our body. Partings we may deplore on personal grounds, the severance of old associations gives us each a sense of corporate and individual loss. But it is our happy experience that there never is wanting 'a supply of men duly qualified to serve' the State, and to safeguard and further the public health by assuming the duties and responsibilities laid by law upon the Council. These duties and responsibilities are many and diverse; it is expedient that the qualifications of the several members should be diverse, and as far as possible complementary. Our statutory constitution provides more fully than many are aware for this wholesome variety of composition. From the beginning nine members only must be registered practitioners, and now only 15 out of 38 need possess a medical qualification. The bodies charged with the *discipline of other professions, such as the law*, have not yet been entrusted with 'this freedom' to receive non-professional members, at the discretion of the appointing authorities.

"In the Council 'diversities of gifts,' including gifts other than professional or scientific, 'diversities of ministrations,' even 'diversities of tongues,' have during my long experience proved to be of real value for our judicial and educational work. The resources of the Council have again and again been enriched by the presence among us of men who were great public *servants, Members of Parliament, municipal* and academic leaders, humane scholars, and the like, recognised outside medicine as eminent in non-professional fields. The Dental Board has profited in many ways by the fact that the Crown appointed as its chairman a Privy Councillor having the parliamentary, administrative, and educational experience of Mr. Acland. Were His Majesty pleased to nominate to our body a member of his Council, whose experience was in like manner complementary to our own, the Council would be similarly advantaged in more than one respect. It would have, in particular, cause to welcome the nomination as marking its close connexion with the Privy Council, to whose official direction we are by statute committed."

*Appointment of a Non-medical Crown Nominee.*

The President then announced that the Lord President of H.M. Privy Council had informed him that afternoon that His Majesty had been pleased to nominate as his representative on the Council, in succession to Sir Francis Champneys resigned, Lieut.-Commander the Right Hon. Edward Hilton Young, D.S.O., D.S.C., R.N., M.P. He referred to the many gifts and attainments of the new representative, who was a man of law and letters, and who had distinguished himself during the war by his gallantry as a naval officer, adding that he hoped that he would attend the Council's *session on the following day.*

*Registration in the Irish Free State.*

"The Privy Council has informed us," the President continued, "that on Feb. 10th the Medical Act, 1926, was passed by the Irish Free State. It continues the Medical Act of 1925 until August 21st, 1926. The new Act gives power to the Executive Council of the Free State to continue its operation for successive periods of one month, until Feb. 21st, 1927, but no further. A despatch from the Governor-General to the Secretary of State for Dominion Affairs intimates that the question of a permanent arrangement in the matter of Medical Registration is engaging the attention of the Free State Government, and a later despatch announces that Ministers hope to be in a position at an early date to ask for a conference with the British Government, for the purpose of discussing a draft Bill on the question. The relations of Southern Ireland to the General Medical Council will therefore remain unchanged until August 21st at least, and medical registration will proceed as hitherto. We have as yet no official knowledge of what permanent arrangement may be proposed by the Free State.

*Reciprocity with Canada.*

"The Privy Council has also communicated to the Executive Committee a telegram from the Governor-General of Canada, in which he says that, at a conference between the *Saskatchewan* Government and the Provincial Medical Council, it has been decided that the recently enacted provincial law shall not be changed. The effect of this law is formally to exclude the registered medical practitioners of the United Kingdom from the privilege of practising in the Province. Reciprocity being thus abrogated by one of the parties, the Order in Council of June 10th, 1915, applying Part II. of the Medical Act, 1886, to Saskatchewan, was rescinded by His Majesty in Council on April 30th. The provincial qualification is thus no longer registrable in this country.

"The *Governor-General* ' *has also informed* the Secretary of State for Dominion Affairs that *New Brunswick* has now finally adopted a position similar to that of Saskatchewan. The Provincial Medical Council informed us in May of last year that it felt that 'the profession must be protected,' and with this object in view it had made an alteration in its Regulations. The alteration excludes from local medical practice practitioners from Provinces of Canada outside New Brunswick who are registered in the United Kingdom. The existing arrangement, however, continues to give practitioners from New Brunswick registered here the privilege of practising in other Provinces of Canada, as well as throughout the Empire. As reciprocity is thus in effect at an end in the Province, the Executive Committee have felt it their duty to represent the facts to the Lord President, with a view to the rescission of the Order in Council of Oct. 14th, 1913.

"Correspondence with other provinces and with the Medical Council of Canada suggests that, until inter-provincial differences of standard and policy have been overcome, and an effective basis for Dominion licensing as distinguished from Dominion examination has been found, no completely satisfactory arrangement for establishing reciprocal relations between this country and Canada as a Dominion will be practicable.

*Indian Examinations.*

"The expected report of Colonel Needham, the Official Inspector of Medical Education in India, on the professional examinations for the degree of M.B. of the University of Calcutta, was duly received and published with the minutes of the meeting of the Executive Committee on Feb. 22nd, 1926. Having carefully considered the report and having had the great advantage of an interview with Colonel Needham, who is at present on leave, the Executive Committee is satisfied that the M.B. diploma of this University does not yet fulfil the conditions for recognition laid down in Section 13 of the Medical Act, 1886. It does not, as it stands, furnish, particularly in respect of midwifery, 'a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice of medicine, surgery, and midwifery' in this country. The Committee is accordingly unable for the time being to propose any change in the existing position of the Calcutta degree. With regard to the question of continuing the present recognition of other Indian degrees, which is still subject to satisfactory reports of progress from the Official Inspector, the Secretary of State for India has informed us that he cordially supports the proposal, originally made by Calcutta, that Sir Norman Walker should pay a second visit to India as a member of the General Medical Council; and further that the Government of India would regard such a visit with favour. Sir Norman *has informed* the Executive Committee that, should he be invited by the Indian Government authorities to pay a second visit to India, he would be prepared, under suitable conditions, to accompany to India Colonel Needham, who is the Official Inspector of Medical Education appointed by the Indian Government and approved by the Council, and to make a special report on his personal observations for the information of the Secretary of State and of the Council. As the existing recognition of other Indian degrees is conditional on the Official Inspector's satisfactory report of progress *in the present year*, an official tour of inspection *falls to be made during the* next winter session. It is obviously convenient that Sir Norman should carry out his visitation then. The members of the Executive Committee gratefully recognise their colleague's readiness to undertake a trying journey in the interest of Indian medical education. They feel sure that, if satisfactory conditions can be arranged for the proposed visitation, in combination with the official inspection of Indian colleges and universities, the opportunities thereby afforded for direct conference with administrative, academic, and professional authorities will once more prove to be of substantial value in removing difficulties and accelerating progress. Moreover, new universities and colleges, including faculties of medicine, are in process of organisation at more than one centre within the Indian Empire. From the correspondence we have already had with these it is clear that they will welcome the opportunity of personal consultation with a member of the Council on the questions of curriculum and examination with which they are occupied.

"A communication has just been received by the Executive Committee from the Secretary of State for India in Council, stating that the Government of India have now agreed to the proposal that Sir Norman should make a further visitation, and that they have invited Colonel Needham to accompany him.

### *British Pharmacopœia.*

"With the approval of the Council, the Pharmacopœia Committee invited delegates from a number of medical, pharmaceutical, and scientific bodies to meet it in conference on certain general questions arising out of the proposed revision of the British Pharmacopœia, 1914. The conference was duly held on Feb. 23rd, and was attended by the members of the Committee and by 23 delegates from 12 bodies interested. To these bodies, and to their delegates, the Committee expresses its obligations for their courtesy in meeting it and stating their views. A number of important suggestions and criticisms were offered by the delegates, bearing chiefly on the scope and method of the proposed revision, on the organisation and powers of expert committees, and on the adaptation of the Pharmacopœia to Indian and Dominion requirements. The Committee, at a subsequent meeting, considered these suggestions and criticisms, together with certain larger questions of pharmacopœial policy, national and imperial, arising out of recent legislation and recent international agreements, including those concerning therapeutic substances, potent remedies, and dangerous drugs. The Committee came to the conclusion that, before making a definite reply on the particular points brought before it at the conference, the general interest required that an authoritative inquiry should be held by a suitable committee, officially empowered to call for information and to examine witnesses on the whole subject of pharmacopœial revision in this country and overseas. The recommendations of such a committee, founded on a comprehensive survey of the ascertained facts, would be of great value from the public, the professional, and the scientific point of view; and would indicate what changes (if any) in the general organisation and method of revision are desirable. A resolution embodying this conclusion of the Pharmacopœia Committee, and asking the Council to take steps towards the institution of such a committee of inquiry, will be brought before you during the session."

### *The Case of Mr. F. W. Axham, Deceased.*

"The Council," said the President, "will remember that towards the end of our session in November, a request was received from Mr. Frederick William Axham that his name, which had been removed from the Register on May 24th, 1911, as the result of a judicial inquiry, might now be restored. Two Royal Colleges, acting independently of each other and of the Council, had subsequently withdrawn from him their diplomas. The Council, which is always ready to entertain requests for restoration, has provided a regular procedure for their judicial consideration. This procedure, which is uniform for all that it may be just to all, is fully set forth in its published Standing Orders. The procedure has been made known to Mr. Axham; but as he was unable to make the required declaration that he held any qualification entitling him to be registered, the Council was legally precluded from dealing with his informal request. It was ex gratia adjourned until this session, however, in case in the interval he should be able to procure the restoration of one or both of his registrable diplomas. The Royal College of Surgeons of England, whose jurisdiction over its members is entirely distinct and independent, on Dec. 10th, 1925, and again on Jan. 14th, 1926, decided that his registrable membership should not be restored. The Royal College of Physicians of Edinburgh, whose jurisdiction over its licentiates is equally distinct and independent, resolved on Jan. 19th, 1926, to restore his registrable licence, on proof submitted that he had 'abstained for the last five years from the practices that led to his suspension and will not resume them.' If Mr. Axham had then presented an application for registration, with a statutory declaration, which he could not furnish in November, that he actually held a medical qualification, and setting forth his recent occupation and intentions as to practice, the application, along with any objection to his restoration that might be submitted by the Royal College of Surgeons, would have been considered by the Executive Committee at its regular meeting on Feb. 22nd, 1926. But at that meeting no such application and statutory declaration from Mr. Axham were forthcoming. The Executive Committee, which has no power to suspend the Council's Standing Orders, were thus unable to consider what recommendation they should make to the Council on the case, and the matter perforce stood adjourned till their next meeting on May 31st. The first application from Mr. Axham which either the Council or the Executive Council could lawfully entertain, with a view to a judicial decision, was, in fact, not lodged until March 4th, 1926, when neither body was in session. The unfortunate death of Mr. Axham, early in April, has to our regret caused the application to be withdrawn from our agenda paper.

"Neither the Committee, as the body charged with preliminary inquiry in such cases, nor the Council acting as a statutory tribunal, has thus had an opportunity of dealing with his application on its merits, of considering any objections to his restoration that might have been submitted by the Royal College of Surgeons or others, or of pronouncing judgment, favourable or unfavourable, upon Mr. Axham's case. Had he survived, the Council would at this session be called upon to exercise its judicial functions in his case, without fear or favour, affection or ill-will. Yet some misguided persons, for selfish ends unconnected with the applicant's interest, thought to sway the tribunal to hasty and partial action by means of popular clamour and denunciation directed against the Council and its members. They abused the complaisance of the press, and misled the uninformed public regarding the facts. And by misrepresentation they sought to excite prejudice against the provisions of the law, expressly enacted to ensure 'that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners.' To these persons that distinction was no doubt professionally inconvenient, and to disparage the Council, whose statutory function is to maintain it, might lead to the easier evasion of the law. The attempt to influence the Council's judgment by threatenings against its constitution, if it did not yield to interested or ignorant demands, anticipated by a month or two the lawless attempt on a larger scale against the national constitution itself. The Council anticipated the firm response of the Government to the much graver attack on law and order. From no single member of the Council did I receive a hint that it should do other than bear the attack with equanimity, and maintain meanwhile the impartiality of its position as a judicial body. No requisition for the summoning of a special meeting of the Council reached me. I am deeply grateful for the unanimous support of the members of the Council in my refusal, as President, to summon it on my own responsibility. That would have been to take action which must tend to bias their opinion, in one direction or another, on a matter submitted for their independent judgment. Two different views were tenable on the merits of Mr. Axham's case, and were, in fact, held by important professional bodies To suggest the preliminary suspension of the Standing Orders, at the instance of interested parties favouring one view, would have been a departure from impartiality on the part of your President. That departure could only prejudice the good name of the Council itself, and so advance the designs of those who sought for reasons of their own to discredit it.

"There is reason to think that the factitious agitation against the Council as an independent tribunal, instigated by unqualified persons under cover of Mr. Axham's name, but joined in by many who, ignorant of the facts, were moved by laudable compassion for his age and infirmities, has led indirectly to a better understanding of the Council's duties in relation to the protection of the public, and to the training and discipline of the medical profession Its stability as a judicial body, not to be swayed from an even course by partisan abuse or threat, has been vindicated anew; as its judicial procedure has oftentimes been vindicated by the High Court of Justice"

Sir Donald MacAlister concluded his address with the statement that several cases of professional discipline, adjourned or freshly presented, would be submitted for inquiry during the week "You will," he said "as always hear them judicially, and decide them on the evidence brought before you, uninfluenced by any outside opinions conveyed to you through the press or otherwise"

A vote of thanks to the President was proposed by Sir NORMAN WALKER, seconded by Sir GEORGE NEWMAN, and carried with acclamation

The Registrar read a communication from the Lord President of the Privy Council, acknowledging the letter of sympathy sent by the Council on the death of Queen Alexandra The Council then proceeded to consider a penal case reported by the Dental Board, and received reports from the Dental Education and Examination Committee The Executive and Dental Executive Committees and the Penal Cases Committee were elected, and membership of other committees was approved The Council then considered four penal cases in which judgment had been postponed from last Summer Session.

## INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MAY 22ND, 1926

*Notifications.*—The following cases of infectious disease were notified during the week: Small pox, 102 (last week 101); scarlet fever, 1311, diphtheria, 511; enteric fever, 27; pneumonia, 610, puerperal fever, 65; cerebro-spinal fever, 7; acute poliomyelitis, 8, encephalitis lethargica, 37; dysentery 8, ophthalmia neonatorum, 73 There was no case of cholera plague, or typhus fever notified during the week.

In London itself there was notified no case of small pox, scarlet fever, 260; diphtheria, 211; enteric fever, 6; pneumonia, 102, puerperal fever, 6; cerebro-spinal fever, 1; encephalitis lethargica, 8, and ophthalmia neonatorum, 15

*Deaths.*—In the aggregate of great towns, including London, there were 3 (1) deaths from enteric fever, 50 (10) from measles, 2 (2) from scarlet fever, 35 (8) from whooping cough, 32 (8) from diphtheria, 13 (10) from diarrhœa and enteritis under 2 years, and 111 (11) from influenza The figures in parentheses are those for London itself

(The Registrar-General's weekly return has not yet been printed, and we are indebted to the Ministry of Health for these figures)

PUBLIC HEALTH LABORATORY AT MADRAS.—The Madras Corporation has accepted the recommendation of its Health Committee for the establishment of a public health laboratory for the analysis and examination of foodstuffs.

# Correspondence.

"Audi alteram partem."

## THE PRECANCEROUS STATE

*To the Editor of* THE LANCET.

SIR,—Allow me to thank you for your perfectly clear and able résumé of my latest paper upon the early epithelial stages of the breast in carcinoma of that gland. Your leading article last week raises the most important point that carcinoma may arise "without being preceded by any of these hyperplastic changes." I quite agree that there is such a state as acute carcinoma—that is to say, one that supervenes very early after the application of tar to the skin. On the other hand, it is a very interesting and an illuminating fact that as a rule tar carcinoma supervenes with great regularity at the end of about six months. During that period various forms of epithelial hyperplasia are observed, as Dr. J. A. Murray has pointed out There is even a stage in which the epithelial hyperplasia is capable of being transplanted, and in its new situation it grows as carcinoma, although the epithelial cells were confined within normal boundaries when Dr. Murray placed them in new surroundings When confined within normal boundaries this state of epithelial hyperplasia cannot be stated to be one of carcinoma, yet the epithelial cells were certainly malignant. Another interesting feature concerning the regularity with which the intervention of carcinoma occurs at the end of six months is this: Supposing Gye be right, that carcinoma be due to a virus and a specific factor, can it be assumed that either one or the other, or both, can appear suddenly with such great regularity? The regularity of the incidence of tar carcinoma at the end of six months appears to me to indicate that the process is a long one and takes (in the mouse) about six months to mature. Proof is wanting as to whether or no that even in acute carcinoma there are any preceding epithelial hyperplastic stages in which the process is invariably rapid. I believe that such is the state of affairs There must be a stage in carcinoma when epithelial cells are malignant and confined within normal boundaries. It must be so, even should a state of carcinoma be the result of the first division of only one cell into two cells The cell from which the invading cell be derived must be a malignant one.

I am, Sir, yours faithfully,

G LENTHAL CHEATLE.

Harley-street, W, May 28th, 1926

*To the Editor of* THE LANCET.

SIR,—In reference to the leading article in your last issue on the above subject may I draw your attention to the important work of Goodpasture[1] and of L. W. Smith[2] on senescence in dogs. They found precancerous changes of common occurrence, not only in the breast and prostate, but in the thyroid, testis, and other organs My own examination[3] of the chief organs of 100 aged men and women showed that changes of a similar nature are often present in human senility. Such widespread prevalence suggests they are natural features of aged tissues It seems highly probable that they are no more than the penultimate stage of normal gland degeneration. After the gland has reached its highest progressive development, the regressive changes which then set in are apparently reversive in character. Just before the final stage of molecular disintegration there is a stage in which proliferation is the dominant feature. One after the other the higher qualities of the cell have gone in an order the reverse of their acquisition, until hardly anything is left but the basic function of reproduction. Should such reduced, embryonoid cells be subjected to the action of suitable stimuli in sufficient intensity or duration, their more or less dormant reproductive faculties are awakened, and in this way cancers are born. There is abundance of evidence that this is the correct interpretation of these precancers and of the way in which they explode into cancers under the stimulus of heat, of X rays, of blows, of tar, or other irritants.

## X RAY TREATMENT OF CANCER.

*To the Editor of* THE LANCET.

SIR,—I regret to find myself in disagreement with about 27 of the statements (original or quoted) of your Ukrainian correspondent, Dr. Podkaminsky, in your last issue. I should at least wish to qualify them materially in any adequate discussion of the issues he raises. The only contribution of his that I can trace in the *Index Medicus* since 1920 (and in the Quarterly Cumulative Index) is a preliminary note on "Gastro-enterostomy with Prophylactic Vagotomy" in last year's *Zeitsch. für Chirurgie* from Prof. Trinkler's surgical clinic at Kharkov. So far as one can judge, his letter is his first contribution to radiological literature. One would be glad indeed to welcome his entrance to the field were his energy, vivacity and remarkable knowledge of English equalled by his mastery of the subject; but they are not. Instead, we are treated to a forensic attack from one whose position in administrative charge of a Rontgen institute would suggest his appearance rather as a defending counsel; and the issues, conflicting as they were, are now more confused as a result of his having mounted the rostrum in your columns.

1. The bases of radiation treatment of cancer are physical, biological, pathological, technical, and clinical. No more than practical physics stands or falls with the Newtonian "laws" does radiation treatment stand or fall with the application or not to it of such theories as the psychological Arndt-Schulz "law," or the Bergonié-Tribondeau "law." "Laws" in science, philosophically speaking, are no more than formulæ which give an account of the main trend of observed phenomena; at any time fresh observations or experiments may lead to their qualification, or even rejection, in favour of more accurate formulæ expressing "events."

2. Few would agree that ionisation measurements have "no advantage over the older pastille and photographic methods"; the latter only measures about 1 per cent. of the incident energy—what possibilities for error are there not here, apart from the characteristic silver radiation error at critical wave-lengths? Compared with ionisation the pastille and photographic methods are obsolete for all short-wave therapy (*x* or *y*).

3. The question of a possible stimulating dose is by no means settled yet, biologically or clinically. I have seen and published notes of four cancer patients (two treated with X rays, two with radium) in whom it seemed justifiable to infer stimulation effects.

4. "Ulman thinks . . . that basal-cell carcinomata hardly ever relapse . . . however the dose may be varied." The opposite is unfortunately the experience of most radiologists at least until their dose-technique is perfected.

5. As to the metaphase cell-division theory of sensitiveness, it would seem illusory to attempt to radiate so as to catch every cell when at this phase. Experiences with some cancers show it is quite unnecessary to attempt treatment on these lines. For example, Kelly's one- or two-minute treatment of rodent ulcer with massive radium doses, and the often successful treatment of lymphosarcoma and testicular recurrences, to name some types that have responded well with either intensive (in time) or fractional methods. Long-continued radiation may be best for squamous-celled carcinoma, but it is a mere supposition that thereby the cells are caught effectively or only in a special period of cell-division.

6. No responsible medical man, whatever treatment he adopts, promises "a complete cure" in cancer (apart from early rodent ulcer). Recent American statistics show a very low percentage (10 per cent. or less) of permanent cure even after breast cancer surgery. How difficult for *any* treatment must be prostatic cancer for example, where early invasion is so common (23 per cent. of patients at first appearance showing bone metastasis (Bumpus, Mayo Clinic); in 2 per cent. only when first seen confined to the prostate (Barringer)). The possibility of distant metastases and late recurrences can justify no claims for permanent "cure" by any known methods of treatment.

These are only a few of the points in Dr. Podkaminsky's letter that are open to criticism. Far from being sunk in "deep pessimism," as he thinks, workers with X rays and radium are perhaps the most hopeful of all those who are treating cancer by recognised methods. Think of the last 20 years' advance in the hopefulness of outlook for the cancer patient who now has radiation as an aid or alternative to surgery! In rodent ulcer, many sarcomas, testicular recurrences, cervix cancer, and breast cancer, the advance is astounding if we think of the problem in a wide way. What may not the next 20 years bring? Radiologists have much to learn yet, but also much cause for solid satisfaction—certainly nothing to justify pessimism in those abreast of the subject, who also realise the protean and baffling nature of the diseases they are attacking. That we cannot cure advanced or disseminated cancer is no cause for depression—no one can show better results than we do in inoperable cases; the same may be true in time of operable ones, though at present early operation, where possible, seems preferable, except perhaps in rodent ulcer, sarcoma, and cervix cancer.

In conclusion, may I say that it seems to me a pity that Dr. Morton has attempted to focus attention on what he terms the "Erlangen system"? There is no such published method of general X ray therapy, only monographs by Wintz on his methods of treating uterine and breast cancer. Even here other methods are, I believe, more widely used; and in surgical Rontgen therapy Holfelder's work seems to me to be the most advanced "system" up to the present. I am at one with Dr. Morton in his plea for a wider study in England of the possibilities of radiation treatment, but such investigations should be on a much wider technical basis than the so-called Erlangen (or any other) "system." And the necessary preparatory discipline and safeguards in the conduct of such extended studies would be difficult to provide. Such studies should include alternative methods of X ray and radium therapy, apart and combined, and in close association with surgical, pathological, biochemical, and physical work. Some centres are already advancing along these lines. The main difficulty is to provide them with funds to epuip them with the necessary space, staff, and apparatus.

In my experience there is little or no lack of clinical material available; a great deal has to be done yet before we could reasonably expect early operable cases to be sent to us in numbers, as Dr. Morton seems to wish. A melioristic outlook seems to me justifiable—somewhere between Dr. Morton's optimism and Dr. Podkaminsky's pessimism.

*I am, Sir, yours faithfully,*

J. H. DOUGLAS WEBSTER.

Chandos-street, Cavendish-square, W., May 29th, 1926.

*To the Editor of* THE LANCET.

SIR,—The letter under the signature of Dr. Podkaminsky, of Kharkow, dealing with the X ray treatment of cancer, though written by a radiologist as if in authority, will, I think, give an entirely false impression on those who have no special knowledge of the subject. It deals with opinions and theories rather than facts. It mentions several laws, for instance, the law of Arndt, Schutz, and the law of Bergonié and Tribandeau as if they were of importance like the laws of the conservation of energy or of gravity. It refers to "the index of karyokinetic activity," "the irritation dose," "the carcinoma dose" as if they were terms based on some profound truths and in common use. On the other hand, the facts of radiology ascertained by experimental and clinical research are hardly mentioned. Nevertheless, dealing thus not with facts but with opinions and theories which are of little or no interest to the radiologist, he finally says "I have now outlined the causes which account for the deep pessimism which is general among rontgen therapists." It is true that the science of radiology advances slowly because of the very small amount of research work which is carried out. If there is any pessimism it is because there are so few facts available and not because some obscure laws and theories and seldom used terms have been found wanting.

I am, Sir, yours faithfully,
J. C. MOTTRAM.
Research Department, Radium Institute,

*To the Editor of* THE LANCET

SIR,—In his reply to my letter in THE LANCET of May 1st, Dr. Reginald Morton maintains his view that the hard X rays have received no careful trial in the treatment of cancer in this country. I need go no further than my own experience to answer his question "Where, when, and under what conditions the trial was made." I submitted 48 cases of cancer of the prostate to this treatment and kept careful record of the results obtained. These cases were not selected in any way, they were consecutive cases from my private practice and were sent to the radiologist as they came to me, without operation. The treatment in these cases was carried out by 12 radiologists, seven of whom work in London; one case was treated at Erlangen. Dr. Morton treated ten of these cases. That was a definite series of cases of a form of cancer readily recognised and easily accessible and thus capable of being accurately watched.

The results of the hard rays in these cases were given in the Ninth Silvanus Thompson Lecture at the Rontgen Society, and were open to Dr. Morton had he cared to attend. They bear out my contention that the claims that have been made for the Erlangen technique are extravagant. In his first letter Dr. Morton stated that treatment by the Erlangen technique was without any of the risks of operation. He now admits that risks do attend the treatment, but he suggests that they do not occur in his own experience and that they are due to carelessness, incompetence, faulty technique, and the treatment of unsuitable cases. I must leave the question of technique to Dr. Morton's radiological colleagues. So far as my own cases are concerned, I can assure Dr. Morton that his colleagues have nothing to learn from him in regard to care and competence. Further, I may say, that in treating my cases Dr. Morton has not been immune from general or local reaction.

Dr. Morton states that he was not thinking of my cases of malignant prostate when he made his statements. I can well believe it. But there was, I think, no harm in informing him of the late results. He further states that he "did not consider any one of them likely to be cured by any method at present known to us." This is the first time I have heard of this view, and I confess that, had I known of it at the time, I should not have advised the patients to undergo the expense and risk of the treatment. The cases are represented as being advanced cases with spread to the bladder and lymphatic glands and with cystitis, and it is further objected that the average age was 62. This account of the cases is quite misleading. I have already stated that with two exceptions they were cases in the early stage of the disease with circumscribed growths. In two cases there was sciatica which suggested a lymphatic deposit but no enlarged glands could be found. The patients were in good and even robust health. The age of 62 is rather under the average age for cancer of the prostate. Does Dr. Morton wish us to understand that the Erlangen technique is contraindicated in malignant disease of the prostate on this account?"

I see no reason to change my view that the claims that have been made in the past for the treatment of cancer by the Erlangen technique have, in my experience, proved extravagant.

I am, Sir, yours faithfully,
Harley-street W., May 31st. JOHN THOMSON WALKER.

## HOUR GLASS STOMACH

*To the Editor of* THE LANCET

SIR,—Mr. Seton Pringle, in his interesting article published in THE LANCET of May 29th, recommends partial gastrectomy as the operation of choice for hour-glass stomach. On theoretical grounds he suggests that the very much easier operation of gastro-gastrostomy would prove to be unsatisfactory. During the last 10 years, however, numerous cases of hour-glass stomach have come under my care and have been subsequently operated upon by different surgeons and by different methods, and I have no hesitation in saying that gastro gastrostomy has given the best results. It has been performed in at least 20 cases, the majority by Mr. R. P. Rowlands. There has been no mortality, and so far as I know recovery has been complete and permanent in every case, although many of the patients were elderly, emaciated women, who had suffered severely for 10, 20, or even 30 years. The operation is, in my opinion, the most satisfactory of all gastric operations; it restores the normal physiology of the stomach at the same time as it promotes the healing of the ulcer by side-tracking the chyme, and there is no danger of jejunal ulcer—an ever present risk after gastro-enterostomy.

I am, Sir, yours faithfully,
ARTHUR F. HURST.
New Lodge Clinic, Windsor Forest, May 30th 1926.

## "TOXIC (SUBDURAL) MENINGEAL HÆMORRHAGE"

*To the Editor of* THE LANCET

SIR,—I was much interested in the account of meningeal hæmorrhage published by Dr. A. G. Banks and Dr. A. M. N. Pringle in your issue of May 22nd. But the title of their paper, Toxic (Subdural) Meningeal Hæmorrhage, is open to question. The appearance of blood in the cerebro-spinal fluid indicates an effusion into the *subarachnoid* space, and in cases of this kind which end fatally the brain is usually found to be enveloped in a thin sheet of blood contained within the arachnoid membrane, the subdural space being free.

I would further quarrel with the use of the word "toxic." In the first of the three cases reported there is, perhaps, some justification for it, though the evidence of subarachnoid hæmorrhage is incomplete. The fluid withdrawn is said to have been "practically pure blood" and "no cerebro-spinal fluid could be separated." This might have been due to accidental puncture of a vein. In true subarachnoid hæmorrhage, as Froin pointed out in 1904, the fluid obtained from lumbar puncture is a mixture of cerebro-spinal fluid with red cells. If it is allowed to stand the blood cells settle at the bottom of the tube, leaving a clear supernatant fluid tinged yellow or brown with hæmoglobin derivatives. In the other two cases, in which a homogeneous mixture of blood and cerebro-spinal fluid was observed, the onset of the illness appears to have been sudden, and the symptoms of constitutional disturbance attributable to the hæmorrhage. A mild febrile reaction is a somewhat characteristic feature of the condition, and together with the signs of meningeal irritation frequently leads to the erroneous diagnosis of meningitis.

I have stated elsewhere my reasons for suspecting that in a large proportion of these cases of spontaneous subarachnoid hæmorrhage in young and healthy people the cause is leakage from a "congenital" aneurysm at the base of the brain. As Dr. Banks and Dr. Pringle suggest these cases are commoner than is generally supposed. I was able to collect 127 instances in 1924.[1] Since then I have read of several others and have myself encountered six. Three of these ended fatally. In two of them a post mortem examination was obtained and revealed a ruptured aneurysm as the cause.—I am, Sir, yours faithfully,

Wimpole-street W., May 2 th. C. P. SYMONDS.

# Obituary.

## SIR JOHN WILLIAMS, BART., G.C.V.O., M.D., F.R.C.P. LOND.

The name of Sir John Williams, who died on May 24th at Aberystwyth, may be unfamiliar to some of the younger generation because he spent many years in retirement, but it is the name of a man who was deservedly famous in his time and who did much to influence the practice of gynæcology and obstetrics. His life was a notable example of the weight of character in a career.

Sir John Williams.

*(We are indebted to the "South Wales News" for this photo by Culliford, Aberystwyth.)*

Born in November, 1840, John Williams came of good yeoman stock. His father, David Williams, carried on a farm in Carmarthenshire, but was also the ordained minister of a Congregational Church; his mother, who was left a widow when John, her third son, was only 2 years old, was a woman of exceptional powers, and brought up her five children with courage and discernment. As a boy, John went to the village school two or three miles from his home. Then he was sent to the Normal College at Swansea, where he took a preliminary course in science and served a short apprenticeship with a medical practitioner. Thence he went to London and entered University College in 1861. After qualifying as L.S.A. in 1865, he held house appointments at the Brompton Hospital for Consumption and at the Children's Hospital, Great Ormond-street, and when he had graduated as M.B. and otherwise equipped himself for medical work went back to Swansea where he settled down as a general practitioner. In 1872 he married Mary, daughter of Richard Hughes, of Ynistawe, who died in 1915. Her mother is still living at the age of 93.

It was in 1873 that Williams returned to London at the instigation of a physician who was visiting Swansea and who insisted that he should apply for the vacant post of assistant obstetric physician at University College Hospital. Somewhat doubtfully he consented, and was immediately appointed. The next 20 years were given up entirely to professional work. Although at first Williams was not very successful in private work it was obvious to his colleagues that his ability was outstanding, and the help of Sir William Jenner and Dr. Matthews Duncan soon increased his practice. He quickly gathered influence and it was not long before his writing and teaching made him a power in the profession. In 1883 he became obstetric physician jointly with Dr. Graily Hewitt, and in 1887 professor of obstetric medicine at University College. Appointment to the Court of Queen Victoria followed, "and his appointment," writes Sir Francis Champneys, "was a sign at which men of good will rejoiced. In this position he was what he always had been, a man who left nothing to chance and who was the soul of honour and uprightness. As a consequence he was absolutely trusted by Her Majesty, who was a shrewd judge of character. He was for some time the undoubted head of his branch." Honours followed in due course. On the birth of the Prince of Wales in 1894 John Williams was created a baronet by Queen Victoria; in 1902 he was made a K.C.V.O. by King Edward, and in 1911, when his work for the advancement of Welsh learning had made him distinguished in another sphere, King George promoted him to the G.C.V.O. The King of Denmark gave him the Grand Cross of the Order of the Dannebrog; the Universities of Edinburgh, Aberdeen, and Glasgow made him LL.D.; he became D.Sc. of the University of Wales, Fellow of University College, and hon. Fellow of the Royal Society of Medicine. In 1903, whilst still in the midst of successful practice, he retired to a country house he had bought at Llanstephan in Carmarthenshire and devoted himself to setting up the Welsh National Library which had been his ideal and became his achievement. His services as a patriot were recognised by his appointment as President of the University College of Wales in 1913 and later by his being made first President of the National Library—"the first in personal effort for its establishment, the first in personal sacrifice for its good, and the first in the importance of his contribution to its treasures."

The renascence of British obstetrics and gynæcology may be said to have begun with the coming of Dr. Matthews Duncan to London. Duncan found a London in which callipers for measuring the pelvis were practically unknown, and where gynæcologists directed their chief attention to such conditions as cervical erosion, minor displacement of the uterus, and the repair of the cervix. Some of the younger men were dissatisfied with the state of affairs, but little was done by way of remedy until Duncan crystallised the discontent around him. Of the band which worked with Duncan, Williams was, perhaps, the senior member, and his power was shown by the number of his pupils who obtained teaching appointments in the London schools. Williams was a skilful operator, which made his somewhat conservative surgery the more impressive. He had no sympathy with the widespread custom of using artificial supports to correct any and every pelvic displacement. The discussion of his paper on the Mechanical Action of Pessaries at the Obstetrical Society in 1876 revealed the conflict of principles on which the practice was based, and his study of the circulation in the uterus given to the same society in 1885 was the chief influence in freeing women from the unnecessary interference to which they were subjected in the name of uterine displacement. His other papers were equally valuable, since he never wrote for the sake of writing. In 1877 he produced a treatise on the Pathology and Treatment of Membranous Dysmenorrhœa, in which again, by his genuinely critical approach, he rendered a service to clear thinking and thus to therapeutics. A second paper on dysmenorrhœa appeared in 1882, and the views he put forward then have since been largely accepted. Five years later he became President of the Obstetrical Society, in the Transactions of which his papers are mostly to be found. Whether great or small they are sound in method and always carried weight, and he was a successful President during his two years of office. Later he became the first chairman of the *Journal of Obstetrics and Gynæcology of the British Empire,* and as a member of the General Medical Council from 1901–11 was responsible for important reforms in the teaching of gynæcology and midwifery.

The last part of Sir John Williams's life was devoted mainly to Wales and the Welsh Colleges. It is said that the sight of John Hunter's collections first stimulated him to be a collector, but however that may be he had already begun to buy Welsh books and manuscripts when he was in practice in Swansea At that time hardly anyone cared for the national literature, and when, about the year 1880, he began to collect in earnest, he had few competitors in the field. Afterwards, when he became wealthy, he never paused to consider prices, but purchased everything available of which a copy was not already in his library Thus he absorbed many great collections, and his own became almost unrivalled. This interest in collecting brought him, in the later 'nineties of last century, into touch with the Welsh Colleges, for he had determined to offer his books, prints, and curios to some institution in Wales as the nucleus of a national collection. Eventually he offered them to the University College of Wales at Aberystwyth on condition that they should find a suitable site for a building. He met the College authorities in 1897, and by the generosity of the then President, Lord Rendel, a freehold piece of land of 14 acres near the town was secured. From this time onwards Sir John Williams took a great interest in the work of the College; in due course he was elected Vice-President, and, on the death of Lord Rendel in 1913, President Meantime the Welsh Members of Parliament had secured a promise from the Government to found a National Library and Museum for the Principality. Vigorous campaigns started in various towns for the honour of being selected as the seat of the new institutions. Sir John Williams took a leading part in advocating the claims of Aberystwyth. He addressed meetings all over Wales and was everywhere received with enthusiasm. Finally, the Government appointed a small commission which decided that the Library should be at Aberystwyth and the Museum at Cardiff. Sir John Williams, naturally, was nominated President of the Library, of which he is considered the founder, and as soon as temporary buildings were available, he presented his great collection of books. In 1911 he had the satisfaction of presiding at the ceremony when the present King and Queen, with whom he had been intimately associated, laid the foundation-stone of the building, which was completed in 1916. There had been a time when the term "national" had suggested to many that the library should contain only Welsh books and manuscripts; but this was far too small an idea to appeal to Sir John Williams, who did not adopt the narrow view of Welsh nationalism. In consequence his library is in process of becoming one of the great libraries of the world. Like the British Museum and four other libraries it enjoys the privilege of receiving a free copy of every book published in Great Britain, and it also has a large annual grant from the Government. Already a great impetus to Celtic studies has been given by the collection in one place, from country houses and peasant homes, of books and manuscripts never previously available for inspection. "The Library," writes Principal J. H. Davies, of the University College of Wales, "will ever remain as the memorial of a far-seeing and single-minded man whose only ambition was to do something to forward the highest ideals of his fellow countrymen."

Sir John Williams was a delightful companion and a good host; he was outspoken, but made few (if any) enemies. He leaves behind him the memory of a kind and truthful man as well as the influence of a great teacher and obstetrician. In the words of Sir Francis Champneys: "Those who are doing good work in a department which has made great advances and stands much higher in the eyes of the profession and the public than it did half a century ago, ought to remember that they owe this largely to such men as John Williams."

There is no heir to the baronetcy.

## SIR JAMES CANTLIE, M.A., M.B., C.M., LL.D. ABERD., F.R.C.S. ENG., D.P.H. LOND.

Sir James Cantlie, who died in a London nursing home on May 28th at the age of 75 years, was a man whose services to medicine were great both in the field of tropical diseases and of first-aid for the sick and wounded. Taken ill last March in Scotland, he was brought to London, where he gradually failed. His death was not unexpected.

SIR JAMES CANTLIE.

James Cantlie was born at Dufftown, Banffshire, on Jan. 17th, 1851, where his father, a banker, was at heart a farmer, and handed on to him a love of outdoor life. Educated at the Milne's Institution, Fochabers, he went on to Aberdeen University, graduating with honours in natural science in 1871, and proceeding to Charing Cross Hospital for the clinical part of his medical study. Before taking his qualification in 1873 he had become demonstrator of anatomy in the hospital, a post which he combined with that of assistant surgeon in 1877, when he took the F.R.C.S At this time he acquired the familiarity with anatomy and surgical technique and the facility for teaching which he was to put to such good use later. In 1887, after taking the public health diploma of the Royal Colleges, he paid his first visit to the Far East, becoming one of the founders of the College of Medicine in Hong-Kong at which he served as dean for a period of seven years. It was then that he came into close association with the man who turned China from an autocracy into a republic; Sun Yat Sen was educated in medicine at the Hong-Kong College and remained throughout his amazing career a close friend of Cantlie. Cantlie was not only Sen's biographer but his rescuer in time of trouble, for it was the personal influence of Cantlie and Manson which secured Sen's release in October, 1896, from the Chinese Legation in London, where he was detained as a prisoner. Cantlie's influence in China was far-reaching, for it was largely owing to him that during the period of its awakening a supply of English-taught medical men became available. And it was not only in China that he satisfied his keen desire to acquire and transmit knowledge of tropical diseases. He joined the Egyptian Cholera Expedition of 1883, inquired into the distribution of leprosy in the East Indian and Pacific Archipelago, and after his return to London became surgeon to the hospital at the Royal Albert Docks, where seafaring men from all parts of the world are received and cared for. He was instrumental in founding the Society of Tropical Medicine and Hygiene, over which he presided for three years, and he inaugurated in 1898 the *Journal of Tropical Medicine*, of which he was joint editor. During this period of his life hardly a year passed without some substantial contribution from his pen to medical science, whether on the surgical treatment of colitis, the therapy of sprue, the ætiology of climatic bubo, or the prevalence of tropical abscess of the liver. Apart from contributions on tropical diseases to the compendiums of Allchin, and Gould and Warren, he edited a translation of Scheube's "Diseases of Warm Countries," to which he added a section on yellow fever. His desire not to miss any important outbreak of the diseases in which he was particularly interested is illustrated by the fact that he was travelling with his wife in Vladivostok when he heard of an outbreak of plague in Hong-Kong; the only way to reach his destination was by a Russian steamer, a passage on which was at first refused. Eventually his wife explained to the Russian officers his reasons for wishing to go, and they were too gallant to refuse her appeal. In 1900, when there was a risk of plague in London, his services were commissioned by Sir Shirley Murphy, who appointed him to visit suspects and assist practitioners in their diagnosis.

Alongside these interests Cantlie was developing that application of surgical principles to the needs of everyday life with which his name is chiefly associated. From 1885 to 1888 he commanded the Volunteer Medical Staff Corps in London, and quite early became chief surgeon to the Metropolitan Division of the St. John Ambulance Brigade. He has been called the perfect teacher, for his graphic touch impressed his points firmly upon his hearers, so that, as one of his pupils has said, it was the humorous remark which came to the aid of memory at the time of trial. Practically unaided he founded in 1914 the College of Ambulance in London. Modern military ambulance was organised in Germany, and it was a source of pride to Cantlie that civil ambulance had its origin in Great Britain as a subject outside the regular teaching of the medical schools. V.A.D. training, which began as long ago as 1908, only took definite form in 1914, when more than 25,000 persons were trained in the elements of life-saving at the College. Unfortunately the economic side of the working was not on a level with the technical, and a scheme which might have been lasting came to a premature end, involving considerable monetary loss to Cantlie himself, who never counted his own risks.

The spirit of joyous adventure which carried Cantlie through his many-sided career made him a source of entertainment in intimate circles. One of his friends recalls the unction with which he sang Charles Mackay's songs or burlesqued the lecturer on parasites, producing specimens from his own person. He justly adds that Cantlie combined Rabelaisian humour with the erudition of a Rabelais. It was in 1918 that James Cantlie received the knighthood of the British Empire. A year later his own university honoured him with the LL.D., and his foreign orders were numerous, from the Imperial Order of Osmanieh (fourth class) downwards. In 1884 he married Mabel, daughter of Robert Barclay Brown, who was the great supporter of his work in public and in private, and bore him four sons. Lady Cantlie died in 1921.

## ERNEST SEPTIMUS REYNOLDS, B.Sc. Vict., M.D., F.R.C.P. Lond.

Dr. E. S. Reynolds, Emeritus Professor of clinical medicine in the University of Manchester, who died on May 22nd, was notable in the profession for his philosophical outlook on medical problems. He was an able neurologist and teacher of hygiene, and will be remembered especially in connexion with an epidemic of beer poisoning.

Born in 1861, Ernest Septimus Reynolds was the son of Mr. J. H. Reynolds, of Manchester, and spent most of his life in that city. He was educated at Owens College, of which he was an exhibitioner, and graduated in science at the Victoria University. In 1883 he took the diplomas of M.R.C.S. and L.S.A. and afterwards spent several years in resident posts at asylums and hospitals, which gave him wide experience. Appointment to the principal Manchester hospitals followed. For 16 years he was visiting physician to the Workhouse Infirmary and he also joined the staff of Ancoats Hospital, to which he became senior physician, and of the Manchester Royal Infirmary. His work and qualities naturally led to his appointment as professor of clinical medicine in the University and in this capacity he found scope for his considerable talents. The Royal College of Physicians of London elected him a Fellow in 1896, and not long afterwards he came prominently before the profession and the public as a result of his researches into the famous beer poisoning epidemic. It was in June, 1899, that unusual symptoms began to manifest themselves among patients attending the Manchester hospitals. Many presented skin eruptions of a more or less indefinite character; there were numerous cases of erythromelalgia or the painful red neuralgia of Weir Mitchell; suffusion of the conjunctiva and nasal mucous membrane was common, and Dr. Reynolds observed a remarkable increase in herpes zoster, which seemed to be in epidemic form. At the beginning of August, 1900, an extraordinary number of cases of so-called alcoholic paralysis were admitted into the Workhouse Infirmary, and the suggestion that this increase was due to wrongful expenditure of money freely circulated after the South African War did not satisfy Dr. Reynolds. Consideration of the incidence made him realise that in this district the so-called alcoholic neuritis was only occurring amongst beer-drinkers and not amongst those who took spirits; and then he noticed the association of the nervous lesions with the herpes and the other forms of dermatitis. Arsenic was the obvious cause of such an association and it did not take him long to find its source. On examining a specimen of beer he found that arsenic was present in considerable quantities, and thus began the controversy which was to rage for many a day. All sorts of ideas were put forward to explain away the unfortunate association of arsenic with the national beverage, but eventually the poison was definitely traced to certain of the sugars used in the brewing process. All these came from the same factory and their presence was afterwards seen to be due to the use of impure sulphuric acid in their preparation. The quantity of arsenic which found its way into the beer varied from 1/30th to 1½ gr. of arsenious acid to the gallon. Although probably many thousands of people were more or less affected by the poisoning it was difficult to give the exact numbers or to say how many cases were fatal, as before Dr. Reynolds discovered the facts the patients were treated for rheumatism, gastritis, diarrhœa, simple skin eruptions, or chronic alcoholism, and, of course, there were many who had no serious symptoms. It was estimated that up to the end of November, 1900, there were at least 2000 cases in Manchester alone, and during the last three months of that year Dr. Reynolds himself had charge of 340 arsenical patients at the Manchester Workhouse Infirmary and treated nearly 500 in all.

As a clinician, Dr. Reynolds won a reputation for lightning diagnosis. Few could sum up a case as rapidly as he did, for he had an extraordinary power of grasping the essentials of an illness and of fixing on the treatment likely to be useful. He was at his best with nervous cases; the border-line of mental and organic nervous disease was specially interesting to him, and his early training in asylum work gave him a groundwork which not many physicians possess. As a lecturer he was not eloquent; he spoke somewhat rapidly and was rather difficult to hear. But he was always worth listening to, for he spoke his own ideas and from his own experience. In 1917 he delivered a Bradshaw lecture to the Royal College of Physicians in which he attempted to put forward a fundamental classification of disease, and in 1920, in a presidential address to the Neurological Section of the Royal Society of Medicine, he applied the principles laid down to the ætiology of nervous diseases. These lectures are deeply interesting as contributions to the study of medicine from an academic standpoint. As an administrator, Dr. Reynolds was quick to make up his mind, and although in the medical school at Manchester he did not introduce many reforms, he quickly saw weak points in schemes laid before the Medical Board and was a critical opponent of them until their defects were remedied. Thus he well served a University which will honour his memory.

Dr. Reynolds was a deputy lieutenant for the county of Lancaster. He married Rosa Maud, daughter of Mr. Thomas Hooker, and leaves one daughter.

# Medical News.

Society of Apothecaries of London.—At examinations held in May the following candidates passed in the subjects indicated:—

*Surgery*—R. V. Cookes, Guy's Hosp.; C. F. L. Hassard, McGill; S. E. Hymans de Tiel (Sect. II.), Royal Free Hosp.; L. O. Jaggnasar, St. Mary's Hosp.; and K. G. B. McMahon, Charing Cross Hosp.

*Medicine*—R. V. Cookes, Guy's Hosp.; M. Escovar, Cambridge and London Hosp.; J. E. Howard, St. Mary's Hosp.; *R. F. Middleton, Birmingham*; *J. Pattis*, Innsbruck and Univ. Coll. Hosp.; A. Purvis, Durham; H. A. Sack, Middlesex Hosp.; M. Stinnesbeck, Frieburg and Royal Free Hosp.; and F. Widlake, Guy's Hosp.

*Forensic Medicine*—R. P. Charles, King's Coll. Hosp.; M. Escovar, Cambridge and London Hosp.; H. J. Fordham, St. Mary's Hosp.; E. J. Jones, Middlesex Hosp.; E. Kessel, Kharkoff and Westminster Hosp.; P. H. L. Moore, Sydney and St. George's Hosp.; A. Purvis, Durham; R. I. Richards, St. Bart.'s and St. George's Hosps.; and H. A. Sack, Middlesex Hosp.

*Midwifery*—A. K. A. Carter, Univ. Coll. Hosp.; L. O. Jaggnasar, St. Mary's Hosp.; K. G. B. McMahon, Charing Cross Hosp.; R. F. Middleton, Birmingham; E. Kessel, Kharkoff and Westminster Hosp.; I. Rivlin, Middlesex Hosp.; and A. D. Shubsachs, Manchester.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery: M. Escovar, C. F. L. Hassard, S. E. Hymans de Tiel, E. J. Jones, E. Kessel, P. H. L. Moore, I. Rivlin, H. A. Sack, and F. Widlake.

University College Hospital Medical School. The Bucknill entrance scholarship, entitling the holder to the course of intermediate medical studies at University College and the final course at the hospital and medical school, will be held on June 29th. The subjects of the examination are chemistry, physics, botany, and zoology.—Two Goldsmid *entrance scholarships entitling the holder to* the final course are offered for competition in June. The subjects of the examination are anatomy, physiology, or general pathology. Further particulars may be had from the secretary of the school.

London Inter Collegiate Scholarships Board. Six medical entrance scholarships and exhibitions of an aggregate total value of £512, tenable in the Faculty of Medical Sciences of University College, and in the medical schools of University College Hospital, the London Hospital, and the London (Royal Free Hospital) School of Medicine for Women, will be offered. The examination will begin on June 29th. *Full particulars may be obtained from* the secretary of the Board, Mr. S. C. Ranner, the Medical School, King's College Hospital, Denmark Hill, London, S.E. 5.

Vacation Course in Climatology.—The Davos Medical Society announces a vacation course, on tuberculosis and the climate of altitude, to be held at Davos from August 22nd to 29th. Prof. K. Dorno will open with two lectures on physical climatology. Prof. A. Löwy will follow on pathological physiology, and Drs. Biland and Hans Staub will deal with pathology. A series of 20 lectures on diagnosis, treatment, and prognosis will be given by the various medical men in practice in the Davos Valley, and two special addresses will be given, one by Prof. F. Sauerbruch, of Munich, on the relations between medicine and general culture, and the other on "Paralipomena," by Dr. Karl Turban. Arrangements have been made for lodging at a moderate price, and the Rhetian railway offers a substantial reduction on its ordinary fares. Information can be obtained from the Commission of Holiday Courses for Doctors, Davos Platz, Switzerland.

National Medical Union.—The thirteenth annual general meeting was held on May 29th, when the following resolution was passed unanimously:—

> "It is certain that in London and the provinces a very large number of insured persons when sick refuse to consult panel doctors, although they are required by law to contribute a fixed sum annually to the salaries of these doctors, and are unable to obtain any rebate towards their medical expenses. The National Medical Union regards this condition as grossly unfair to the insured, and while expressing its great surprise at the silence on the subject in the report of the recent Royal Commission on the working of the National Insurance Acts earnestly invites the Minister of Health to examine the subject with a view to giving fair play to such insured persons as do not wish to consult Government doctors."

The Union claims to speak for the non-panel element in the profession and thus to represent over 30 per cent. of the medical men in the country.

Royal Institution.—A general meeting of members will be held on Monday, June 7th, at 5 P.M. On Wednesday, June 9th, at 5.15 P.M., Prof. Joseph Barcroft will lecture on the Lungs, and on Thursday, June 10th, at 5.15 P.M., Mr. Newton Friend, D.Sc., will lecture on Science in Antiquity.

Dr. C. M. Rolston (Chief Medical Officer) has been appointed by the King an Official Member of the Executive Council of the Presidency of Dominica and an Official Member of the Legislative Council of that Presidency.

Glasgow Post-Graduate Medical Association. Arrangements have been made for post-graduate teaching in Glasgow which include a general medical and surgical course from August 16th to Sept. 11th, special courses in various subjects, and clinical assistantships. The syllabus for the summer session and other information may be had from the secretary of the Association, at the University, Glasgow.

Röntgen Society.—The annual general meeting will be held on Tuesday, June 8th, at 8.15 P.M., at 32 Welbeck-street, London, W. Following the election of officers a paper will be read by Mr. A. E. Speight entitled Abstracts from Apparatus and Technique for Radiography of the Accessory Sinuses, and a paper by Mr. L. A. Levy, D.Sc., and Mr. D. W. West on a New Method of Dosage for Use in Actinotherapy.

London Dermatological Society.—The annual oration will be delivered on Wednesday, June 16th, at 1.30 P.M., by Sir Humphry Rolleston, at St. John's Hospital, Leicester-square. His subject will be the Relations of Dermatology and General Medicine. The annual dinner of the society will be held at the Trocadero Restaurant at 6.30 P.M. for 6.45. Sir Humphry Rolleston will be the guest of the Society.

The Site of Bethlem Hospital.—At a recent meeting of the London County Council, Lord Monk Bretton, Chairman of the Parliamentary *Committee, gave* explanations as to the future of the site of Bethlem Hospital which was recently purchased by Lord Rothermere for a public park to be named after his mother, the late Geraldine Mary Harmsworth. The Corporation of London are the freeholders and in consideration of the Monks Orchard site of the new hospital being handed over to them they will vest the South London freehold in the London County Council. The old buildings are to be removed by the governors of Bethlem "unless otherwise agreed between the governors, Lord Rothermere, and the Council." It is greatly to be hoped that these interesting buildings will be preserved.

Bicentenary of the Edinburgh Medical Faculty.—This year marks the bicentenary of the Faculty's foundation and arrangements are now complete for the special celebrations on June 10th and 11th. A dinner is to be held in the upper library of the old College on June 10th, at which many distinguished guests from abroad and from this country will be present. There will be an honorary graduation in the McEwan Hall in the morning of June 11th, when an address will be given by Sir George Newman, Chief Medical Officer of the Ministry of Health, and thereafter a service will be conducted in St. Giles Cathedral by Prof. W. P. Paterson. The honorary graduates will be entertained to luncheon by the Royal College of Surgeons and in the afternoon Sir John Gilmour, Secretary for Scotland, will open the reconstructed department of surgery, which includes the new research department. This ceremony will take place in the McEwan Hall. In the evening the Royal College of Physicians will entertain the honorary graduates to dinner, and the celebrations will end with a reception in the Royal Botanic Gardens.

Celebration of Prof. Richet's Jubilee.—The celebration of the jubilee of Charles Richet last week at the Paris Academy of Medicine was attended by many persons of high standing, including Mr. Painlevé (Minister of War), Marshal Foch, Mr. Henneguy (President of the Society of Pathology), Prof. Roger (Dean of the Paris Faculty of Medicine), *Prof. Bar (President* of the Academy of Medicine), Prof. Gley (of the College of France), and Prof. Frédéricq (of Brussels). The last named invested Prof. Richet, on behalf of the King of the Belgians, with the insignia of Grand Officer of the Order of Leopold. Marshal Foch then, in the name of the President of the French Republic, pinned on his breast the emblem of Grand Officer of the Legion of Honour. After a series of short addresses by Prof. Richet's fellow scientists Mr. Painlevé congratulated him on his brilliant career and offered to him a jubilee book and his bust in bronze executed by the sculptor Landowski. In his reply, Prof. Richet expressed his gratitude not only to those who were present, but also to such of his collaborating masters and colleagues as had passed away.

A Russell Lodge bed, endowed by the Tinfoil (Hospital) Fund of the Ancient Order of Druids, has been dedicated at the Royal Northern Hospital.

Dr. J. R. Leeson, J.P. for Middlesex, has been unanimously appointed Charter Mayor by the Twickenham Incorporation Committee.

On May 28th Dr. George Alexander Pirie, of Dundee, was presented with the Carnegie Hero Fund award of a bronze medallion and the first instalment of £100 towards an annual allowance of £200. Dr. Pirie has become permanently incapacitated as the result of injuries received during work with X rays.

The Cancer Hospital, Kensington.—A course of post-graduate lectures will be given at the Cancer Hospital in June and July at 4.30 P.M., the lecturers including Mr. W. E. Miles, Mr. Cecil Rowntree, Sir James Dundas-Grant, Mr. P. P. Cole, Mr. C. A. Joll, Dr. E. S. Rowbotham, Mr. C. E. Shattock, Dr. Robert Knox, Mr. R. Jocelyn Swan, Sir Thomas Horder, Dr. A. Leitch, and Dr. Stanley Wyard. The first lecture will be delivered at 4.30 P.M. on June 9th by Mr. Miles on Carcinoma of the Rectum, and Mr. Rowntree will lecture on June 11th on Cancer of the Breast. Subsequent lectures will be announced in our Medical Diary.

British Hospitals Association.—The sixteenth annual meeting and conference will be held in the Town Hall, Portsmouth, on June 24th and 25th, Sir Arthur Stanley presiding. The first day programme includes an address by Dr. H. L. Eason on Pension Schemes for Officers and Nurses, and one by Sir John Paget, K.C., on Street Accidents and Compensation Cases. On the second day Dr. S. C. Dyke will read a paper on the Pathological Service of the General Hospital. A discussion will follow each of these addresses. In the afternoon of June 25th visits will be paid to Portsmouth Hospital, Royal Naval Hospital, Haslar; H.M.S. *Victory*, a battleship, and a submarine. Further particulars may be obtained from the secretary of the Association at 33, Bloomsbury-square, London, W.C. 1.

Presentation to Sir Frank Colyer.—At the annual general meeting of the Odontological Section of the Royal Society of Medicine held on May 31st, a presentation was made by Mr. Lewin Payne, President of the Section, to Sir Frank Colyer in recognition of his services as honorary curator of the Odontological Museum. An address was presented to Sir Frank Colyer, and a sum of £200 subscribed by members of the Section will be used for a Colyer prize to be awarded triennially to dental surgeons of not more than five years' standing for the best piece of research in some branch of dental science. The Odontological Museum was founded by the old Odontological Society. When the society was merged in the Royal Society of Medicine the museum was entrusted to the Royal College of Surgeons, which undertook responsibility for its upkeep. The museum still retains its separate identity and its curator is appointed by the Odontological Section of the Royal Society of Medicine. Under Sir Frank Colyer's devoted care it has been greatly enlarged and the Council of the Royal College of Surgeons has recently decided to enlarge the available accommodation by about one half. Largely owing to the work of Sir Frank Colyer the Odontological Museum is probably the finest collection of dental specimens in the world.

Endowment of a British College of Nurses.—The *British Journal of Nursing* for May contains the announcement of an anonymous donation of more than £100,000 to found a British College of Nurses, to be composed at first of Foundation Members, all of whom will be registered women nurses, and of Foundation Fellows occupying responsible official positions in the nursing world. After an initial period of grace membership will be limited to registered nurses who pass an examination and pay an entrance fee. Such a diploma, it is suggested, will become essential for those who wish to gain higher posts in the nursing profession, and the higher professional status offered is designed to attract candidates of a desirable type to adopt nursing as their profession. The Council of the College will appoint lecturers, teachers, inspectors, and examiners; will offer legal advice to its Members and Fellows, and provide for their assistance in sickness, accident, or old age. The founders of the College intend that its work shall be attended with due ceremony; its meetings are to be opened with prayers; Members and Fellows will be required to take a solemn oath and to give an undertaking of professional and personal conduct, and members of the Council will be entitled to wear a distinctive academic robe. The two trustees, whose names are not mentioned but one of whom is stated to be the treasurer, are to nominate the officers of the first Council, and, as soon as the complete Council has been nominated, further information will be available from 431, Oxford-street, London, W. 1.

As we go to press we learn with deep regret of the death of Sir William Leishman, Director-General, A.M.S., after a short illness.

A New Children's Hospital.—Sir William Hamer, the late chief medical officer of the London County Council, has opened a small children's hospital in the grounds of the Rye-lane Clinic, Peckham. Children suffering from adenoids and tonsil troubles are to be treated there. Hitherto they have had to go to Woolwich or one of the general hospitals.

James Mackenzie Institute for Clinical Research.—On Monday, June 14th, at 4 P.M., Dr. Maitland Ramsay, hon. director of the Institute, will give the introductory lecture of the post-graduate course to be held at St. Andrews from June 14th–30th. His subject will be the Principles of the Reflex Arc as applied to the Function of Vision. Particulars of the course may be had from the secretary.

A Year of St. Bartholomew's Hospital.—The annual report of the treasurer, Lord Stanmore, has just been issued. It is, as usual, one of the fullest and most interesting of hospital records, and contains much in the way of statistics and other information of value to those who are professionally concerned with hospital work in any form. The in-patients numbered 9191; the casualty patients 66,601, and during the year 2714 cases of street accidents or illness were brought in. At £184,000 the income showed a reduction of £22,000, chiefly accounted for by a drop in legacies. The second block of Queen Mary's Home for Nurses, which will bring the number of bedrooms up to 257, will be ready for occupation during the present month. It is stated that in the near future it will be necessary to make a material addition to the nursing staff to allow a sufficient margin for holidays, illness, and emergencies, and to provide facilities for study.

The late Major H. Dutch.—Major Henry Dutch, who died on April 30th after a long illness, was born in Dublin 64 years ago. He was trained at Coombe Hospital, Dublin, and at Middlesex and St. Mary's Hospitals, London, taking the diploma of L.R.C.P. Lond. in 1886; ten years later he became M.D. Brux. For over 30 years he practised in Mayfair with great success, and he was a notable figure in the district. A member of the Westminster City Council, he represented the Grosvenor ward for a quarter of a century, and previously he had been a member of St. George's vestry. From 1899 onwards he was public vaccinator for the St. George's, Hanover-square district. During the war Major Dutch was attached to the 4th (City of London) Royal Fusiliers and was physician to the Bancroft Military Hospital; he was also on the staff of the Assistant Provost-Marshal, London district. In 1918 he invented the aurorascope, which has been widely used by practitioners. Major Dutch leaves a widow and one daughter, who is also a member of the Westminster City Council.

# Medical Diary.

## SOCIETIES.

ROYAL SOCIETY, Burlington House, W.

Thursday, June 10th.—4.30 P.M., *the following papers will be read:* A. V. Hill: The Viscous-Elastic Properties of Smooth Muscle. A. S. Parkes: (1) Observations on the Œstrous Cycle of the Albino Mouse. (2) On the Occurrence of the Œstrous Cycle after X Ray Sterilisation. (Communicated by Prof. J. P. Hill.) Isabella Gordon: The Development of the Calcareous Test of *Echinocardium cordatum.* (Communicated by Prof. E. W. MacBride.) J. Walton: Contributions to the Knowledge of Lower Carboniferous Plants. (Communicated by Prof. F. E. Weiss.) J. H. Priestley and E. Rhodes: On the Macro-Chemistry of the Endodermis. (Communicated by Dr. F. F. Blackman.) D. Keilin: A Comparative Study of Turacin and Hæmatin and its Bearing on Cytochrome. (Communicated by Prof. J. Barcroft.) E. Ponder: The Equations applicable to Simple Hæmolytic Reactions. (Communicated by Sir E. Sharpey Schafer). J. P. Hoet and Phyllis Kerridge: Observations on the Muscles of Normal and Moulting Crustacea. (Communicated by Prof. A. V. Hill.) C. H. Best and H. P. Marks: Additional Note on the Effect of Insulin on the Lactacidogen Content of the Skeletal Muscles. (Communicated by Dr. H. H. Dale.)

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Monday, June 7th.—8.30 P.M.—Social Evening. Fellows, Members of Sections, and their friends will be received in the Library by the President, Sir StClair Thomson. 9.30 P.M., Mr. Frederick T. G. Hobday (President of the Section of Comparative Medicine) will give an illustrated address on Our Animal Friends as Patients.

WEDNESDAY —4 30 P.M., SURGERY SUBSECTION OF PROCTOLOGY Specimens will be on view at 4 P.M. Annual General Meeting Discussion The Value of the Closed Methods in Resection of the Colon. Openers Prof John Fraser (Edinburgh) and Mr Seton S. Pringle (Dublin). Other speakers Dr T de Martel (Paris) Mr Grey Turner, Mr Ernest Miles, and Mr Lockhart Mummery

FRIDAY —8 30 P.M., OPHTHALMOLOGY (Cases at 8 P.M.). Dr Ransom Pickard The Visual Field in Atheroma of the Retinal Vessels. To be followed by the Annual *General Meeting.*

## LECTURES, ADDRESSES, DEMONSTRATIONS &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W

TUESDAY, June 8th.—5 P.M., Sir Thomas Lewis Observations upon Blood vessels of the Human Skin. (First Croonian Lecture )

THURSDAY —5 P.M. (second Croonian Lecture)

NORTH EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N

MONDAY, June 7th.—10 A.M., Surgical Out patients Mr. W E. Tanner 10 30 A.M., Gynæcological Operations Mr A. E. Giles: Throat, Nose, and Ear Operations Mr W Ibbotson 2 P.M., Medical Surgical, and Gynæcological Clinics, Operations, 6 30 P.M., Venereal Department.

TUESDAY —2 P.M., Medical, Surgical, Throat, Nose and Ear Clinics, Operations.

WEDNESDAY —10 30 A.M, Surgical Operations: Mr E. Gillespie. 2 P.M., Medical, Eye, and Skin Clinics, Operations. 3 P.M., Dr. Oliver Selected Cases of Skin Disease 5 30 P.M., Venereal Department.

## COMMON SKIN COMPLAINTS IN CHILDREN UNDER FIVE.[1]

By A. M. H. Gray, C.B.E., M.D., F.R.C.P. Lond.,

PHYSICIAN FOR DISEASES OF THE SKIN, HOSPITAL FOR *SICK CHILDREN, GREAT ORMOND-STREET.*

My remarks are particularly directed to those skin *conditions of children* under 5 years of age which can be *prevented or dealt* with in child welfare centres.

### The First Year of Life.

*Miliaria Rubra.*—One of the commonest eruptions seen in small infants, often within the first few days of life, is an eruption of pin-head sized papules each surmounted by a small vesicle, the lesions being discrete and not tending to run together and situated chiefly on the trunk, but sometimes on the face. This is a *condition associated* with excessive sweating and is *also* called "red *gum rash.*" It nearly always occurs in infants who are too warmly clad or are kept in hot, stuffy rooms. It subsides very quickly when the cause is removed and if calamine lotion is applied.

*Pemphigus Neonatorum.*—This is a condition in which blisters, varying in size from a pea to half-a-crown, or even larger, occur on the skin of an infant. It is merely an infantile form of *impetigo contagiosa,* and is in the majority of cases due to surface streptococcal infection. Generally the infection can be traced to a whitlow or septic patch on the skin of the mother or nurse. The blisters may commence in any part of the body and obviously spread by local infection. In some severe cases the horny layer of the epidermis *over the* whole body is rapidly separated from the *underlying layers of the epidermis, leading to a rapidly fatal* termination. This latter condition is, fortunately, very rare and is known as Ritter's disease or *dermatitis exfoliative neonatorum.* Pemphigus neonatorum has to be distinguished from congenital syphilitic pemphigus, which is, however, a symmetrical eruption involving chiefly the buttocks, palms, and soles, and is associated with other signs of syphilis, such as wasting, snuffles, the syphilitic wig, and typical syphilitic papules and macules. Pemphigus neonatorum is readily cured, if seen early, but if extensive may terminate fatally. In treatment one of the main points *is to prevent loss of heat by the application of large wet dressings to the* infant. Ointments, however, are *not very* suitable for such moist lesions. I usually advise pricking the blisters and mopping up the fluid carefully, followed by the application of a dressing soaked in lin. calamin. (B.P.C.) to which 1 per cent. or 2 per cent. of hydrarg. ammon. *has been* added, care being *taken only to expose* a small area at a time and covering *the* dressing with cotton-wool.

*Napkin Rashes.*—It is very common to find red erythematous areas developing under the napkin, chiefly on the scrotum, penis, and buttocks, but also extending down the thighs and sometimes *involving the* heels, when they *come* in contact with the napkin. This is known as intertrigo. This condition may be due to infrequent changing of the wet diaper, or to excessive acidity or akallinity of the urine and fæces, or even to carelessly washed-out napkins. The general principles underlying the rectification of abnormal conditions of the urine and fæces by diet and the *administration of alkalis,* &c., would *take* more time than I have at my disposal. As regards local treatment, however, it will generally be found that simple powders and lotions are usually insufficient to afford protection to the skin once it has become inflamed, and I think you will find that *calamine liniment*, which contains equal *parts of olive* oil and lime water, is a *more suitable application.* It is very important to treat the condition in the early stages, as there is a considerable tendency for the eruption to spread and produce a generalised eczema, the trunk, limbs, and face becoming involved in turn. *There is another type* of napkin eruption which is not *uncommon and* that is a papular or papulo-erosive type (the so-called *Jacquet's erythema*). Here we find a number of rather large papules scattered over the prominences of the buttocks, thigh, and scrotum, and sometimes on the calves of *the* legs and heels; they are quite discrete and often eroded on the surface. The chief difficulty arises in the diagnosis from syphilitic mucous patches. In this latter condition, however, the lesions are not confined to the prominences but occur also in the folds, other parts such as the palms, soles, and peri-oral region may be affected with an eruption, while the general signs of syphilis, mentioned above, are generally present. The Wassermann reaction is valuable in doubtful cases. The treatment of Jacquet's erythema is the same as for intertrigo.

---

[1] A paper read at a recent meeting of the Maternity and Child Welfare Group of the Society of Medical Officers of Health.

*Facial Eczema.*—This is a common and troublesome condition met with in infants. The subject has recently been fully discussed at the Royal Society of Medicine.[*] There are, in my opinion, at least three types: (1) cases starting on the cheeks or forehead, the primary facial type; (2) cases starting on the scalp and involving the face later; and (3) cases complicating eczematous eruptions which commence in other parts of the body. This last type has been referred to, in part, when dealing with napkin eruptions. The two other varieties require special consideration. The primary facial type almost always occurs in fat and florid infants, who generally give a history of overfeeding. They are ravenous feeders, pump up their food, and are generally constipated. The eruption appears to start as the result of friction, possibly because the gastro-intestinal disturbance causes facial congestion and itching. There is no doubt also that the external temperature plays an important part, as these cases are very much more frequent in the winter than in the summer. There can also be little doubt that the infants who suffer from this condition have an inherent sensitiveness, not only of the skin, but also of the mucous membranes, for they are very prone later in life to develop asthma and a curious itchy condition of the skin, which we call flexural pruritus and which leads to a troublesome form of friction dermatitis. The majority are breast-fed infants. The rash, which first commences on the cheeks or forehead, spreads all over the face, chiefly attacking the prominences, and may then involve the scalp and parts of the trunk and limbs. It may be of the dry, scaly type, or more often is moist, weeping, or crusted. I do not know whether careful feeding will prevent the onset of this condition, but I think a good deal can be done when the disease is established by careful reduction of the food. An important part of the treatment, however, at this stage is local treatment. The child must be restrained from scratching and rubbing by fixing down the hands, splinting the elbows, &c., but it is even more important to try to stop itching. This is best done by keeping the child at as even a temperature as possible and applying a face mask spread with Lassar's paste to which 3 per cent. crude coal-tar has been added. Sedatives, such as bromide and chloral, may sometimes be called for if sleep is much disturbed. The condition clears up in practically all the cases at the end of the first winter of life, even if treatment has not cured it before. The cases starting on the scalp almost always begin with slight scaly patches, sometimes occurring in rings, which run together and form a dirty scaly sheet over the vertex. Sooner or later the irritation set up by this causes the child to scratch, and by friction and secondary infection an eczematous eruption is produced. This may spread to the face and eventually involve other areas of the body. The original scaly patches are almost certainly produced by the bottle bacillus and luckily they can be readily dealt with by the application of weak sulphur and salicylic acid ointment (gr. xv. of each to ℥i.). It is possible, therefore, in the majority of cases to prevent eczematisation. If, however, this sets in, it is usually necessary to treat it on the lines laid down for the primary facial type. In these cases diet seems to have little or no effect on the production of the eruption.

*Rarer Conditions.*—These are the commonest eruptions met with in infants, but perhaps a reference to two other conditions, which may occasionally be seen, will not be out of place. We sometimes see infants with a group of *blackheads*, often associated with inflammatory papules or pustules, on the upper chest, chin, or cheeks. These are usually produced by rubbing in camphorated oil, but in some cases olive oil is the causative factor. The lesions subside slowly if the irritant is stopped. Occasionally we meet with infants with sharply defined large raised red swellings, often surmounted by a crust or studded with small pustules, situated on the face or limbs. These lesions are characteristic of a *bromide eruption*, and it must be remembered that it is often the mother who is taking the bromide and not the infant. The lesions subside slowly on discontinuing the drug.

### AFTER THE FIRST YEAR OF LIFE.

*Impetigo Contagiosa.*—The appearances of this eruption will be familiar to you. The earliest lesions are lentil- to pea-sized very thin-walled vesicles, which either rupture at once or become turbid if they persist for a few hours. When ruptured, the serum oozing from the base dries and forms a crust which may be transparent and amber-coloured or of a dirty greenish colour according to the number of leucocytes which exude. Occasionally the vesicles do not rupture early, but increase in size and form large blisters (*bullous impetigo*), or the lesions may spread at the edge and crust in the centre (*circinate impetigo*). The lesions are due to a surface streptococcal infection. In simple cases the treatment consists in carefully removing the crusts and applying a mild antiseptic ointment. Crusts can be removed either mechanically, by soaking in a weak lysol solution, by the use of warm olive oil, or, in cases where they are numerous and massed together, by starch poultices. It is best to apply the antiseptic in a stiff ointment, such as Lassar's paste, and 3 per cent. ammoniated mercury or yellow oxide of mercury are the most useful antiseptics to employ. In the bullous form lotions are more useful; the bullæ should be pricked, the fluid carefully mopped up, and 1 in 1000 acriflavin dressing applied and changed every four hours. Impetigo contagiosa has an unpleasant habit of attacking the folds behind the ears and below the lobules of the ear, the angles of the mouth, nose, and eyes. In these positions fissuring is apt to occur and healing is delayed. The principles of treatment are the same, but precautions must be taken to prevent the opening of these fissures. Thus, the ear must never be drawn out while dressing it, and, in the case of the mouth, it may be necessary to apply a piece of strapping to prevent the extreme corner of the mouth from opening. Impetigo in the region of the ear is often the starting-point of a *septic dermatitis of the scalp*, one of the most troublesome conditions we have to deal with in children. It would be beyond the scope of this paper to discuss the treatment of so chronic a condition, but efficient treatment of an impetigo may prevent this condition. Impetigo contagiosa is often secondary to other conditions and it is necessary to look for such. Thus, impetigo of the scalp is frequently due to pediculosis, of the ears to otorrhœa, of the mouth to nasal discharge, of the limbs to scabies and papular urticaria.

*Pityriasis Alba.*—This is one of the names given to those dry, pinkish, scaly, and sharply defined patches often seen on children's faces. Sometimes they are due to constant wetting of the face, as in children with adenoids, who dribble at night, possibly sometimes they are due to the use of irritating soaps, certainly in some cases they are low-grade streptococcal infections. In the former cases the cause must be removed; in the latter an ointment of 3 per cent. salicylic acid and 3 per cent. ammoniated mercury will usually cure.

*Urticaria Papulosa.*—This is a very common condition in young children. It sometimes commences in infancy, but usually in the second or third year. The eruption consists of erythematous patches, with a central pin-head to lentil-sized papule. The erythematous zone soon subsides, but the central papule, which itches intensely, is scratched and persists, surmounted by a small blood-stained scab. These scratched papules are chiefly seen on the extremities and lower part of the trunk. Not infrequently vesicles or even bullæ may develop, especially on the feet. The spots come out in crops, and may be more or less continuous or may be intermittent. They are much more common in hot weather. We know very little of the cause of this condition; it does not usually appear to be due to specific protein sensitiveness, but many cases clear up if the diet is modified. A considerable number seem to improve if sugar is cut down; a few are improved when specific articles of diet, such as eggs, porridge, bananas, &c., are excluded, but in general it may be said that treatment should be directed to carefully regulating the digestion and in seeing that the child is appropriately clothed. It is also well to satisfy oneself that the child is not suffering from worms. Local sedatives are of considerable value in these cases, tar baths and tar lotions being the most useful. In some cases a good deal of damage is done to the skin by scratching and small traumatic ulcers covered by adherent crusts form, chiefly on the lower limbs. To this type of lesion the name *ecthyma* has been given. Ecthymous lesions occur in other conditions besides papular urticaria where scratching and septic infection are combined; they are best treated by removal of the crusts and the application of a dressing spread with yellow oxide of mercury in Lassar's paste referred to under impetigo contagiosa.

*Scabies.*—This condition is the only one likely to be confused with papular urticaria. The scratch eruption on the extremities is sometimes very similar and the eruption of vesicles and small bullæ on the hands and feet may occur in both conditions. Scabies lesions, however, are apt to be much more pustular than those of urticaria papulosa and a good deal of independent impetigo is often seen in the former condition. The diagnosis rests, however, on the presence of acarine burrows, chiefly found on the hands and insteps in children. It is almost always possible to see, with a lens, the shiny white round body of the female acarus at the end of the burrow, and this can easily be removed with a needle for microscopical examination. In addition to the burrows, the upper limbs, front of the trunk and thighs, buttocks, and back of the thighs are generally covered with a fine follicular papular eruption, which shows signs of much scratching. Further, we often have a history of other cases in the house. It is important in cases of scabies to examine the parents or other relatives of the children affected. Quite a number of people have scabies and suffer from little or no itching; they are for practical purposes carriers. Unless these cases are located, reinfections are common. The treatment of scabies is well known.

---

[*] THE LANCET, 1925, ii., 1333.

*Pediculosis.*—Pediculosis capitis is common in children and is usually symptomless, but is sometimes associated with impetigo. I find that the treatment recommended by Whitfield of tying up the hair for an hour in a hot 1 in 40 compress to be the most satisfactory treatment in out-patient practice. Rarely one finds the eyelashes of small children infected with pediculi pubis. The only treatment here is to remove the insects and their nits with forceps.

*Ringworm.*—The diagnosis and treatment of ringworm are such large subjects that one cannot adequately deal with them here. With regard to scalp ringworm, however, one or two points may be of interest. It is a good cardinal maxim, I think, to consider all scaly patches on the scalp of children, other than those of quite small infants, as ringworm until a careful examination has failed to reveal the evidence of this disease. In most cases proof is easily forthcoming if the patches are carefully examined for the stumps with a lens. In one of the rarer varieties of ringworm, however (viz., in one endothrix type), stumps may be very few and far between and not arranged in groups so as to show patches of hair thinning and the scurfiness may be very thick and very extensively distributed over the scalp. In these cases a prolonged search is necessary, and all suspicious hairs should be removed and microscoped. There is far too much ringworm of the scalp at the present time, and if it could be impressed upon parents that all scaly patches on the scalp should be examined by a doctor, a good deal of the disease would disappear. I am keenly sensible of the efficiency of the school doctors and nurses in getting hold of early cases, but if parents were also on the look out the cases would come for treatment still earlier.

To sum up, I think we may say that some skin conditions such as miliaria rubra and possibly urticaria papulosa may be prevented or modified by proper clothing, that much can be done in the prevention of napkin rashes and eczematous eruptions by careful toilet, and the avoidance of irritating soaps; that impetigo, pediculosis, and scabies can be avoided or modified by simple cleanliness, and this is especially applicable to the scalp, which is often much neglected. It is probable also that careful hygiene of the scalp would diminish and almost stamp out ringworm. Lastly, careful feeding will probably modify or even prevent certain types of facial eczema and some cases of papular urticaria.

---

## CALVERLEY'S "ODE TO TOBACCO."

MR. E. L. Calverley, nephew of the poet, writes, apropos of the footnote on page 961 of our issue of May 22nd, that the statement about the "Ode to Tobacco" being wrongly attributed to C. S. Calverley, being really written by the two Miss Hodgkins is without foundation. The question was raised two years ago and definitely contradicted by the survivor of the two sisters—the widow of the Right Hon. Sir Edward Fry, Lord Justice of Appeal. In a letter to Sir Henry Newbolt she wrote that their ode did not resemble Calverley's.

## THE PROTECTION OF AN ARMY AGAINST VENEREAL DISEASE.

THE control of prostitutes and venereal disease in armies presents problems that have defeated many great commanders. After the war a particularly difficult situation had to be faced in the armies of the Rhine, and amongst the British troops there the venereal disease rate was two to four times as high as that of the Army generally. In the *Military Surgeon* for April Major M. A. Reasoner, of the American Medical Corps, gives an account of a somewhat original method for combating venereal disease which was adopted by the United States forces in Germany. Prostitutes, he says, were drawn to the occupied area from all Central Europe—even from Poland—and it was difficult to deal with them under German law. Venereal disease began to increase amongst the troops, and every effort had to be made to keep it down. All the usual measures were tried, education, athletics, prohibition of spirits and strong wines, frequent inspection, the offer of standard means of prophylaxis, the placing of registered houses out of bounds. But though all of them may have done good, Major Reasoner contends that the most useful was the institution of vagrancy laws. A vagrancy court was set up to deal with any persons not naturally domiciled in the American occupied area who were found without means of support; such persons were sentenced to terms of imprisonment, and the women were examined in prison for venereal disease. About one-third of them were found to be infected—generally with gonorrhœa—and these were sent at once to hospital, where they remained until they were cured. The great hospital for prostitutes set up by the United States at Bendorf, containing 300 beds, proved a blessing both to Germany and to the troops. Although complete statistics are not given, it seems certain that the amount of infection really was diminished. As for those men who did contract it, they were sent to a hospital on an island where they were kept by themselves until they were cured. Here they were taught to shoot, educated in soldiering, and thoroughly drilled; so that they returned to their units more efficient than when they left them.

## FIRST AID.

A SECOND edition, revised, of Questions and Answers in First Aid (pp. 21, 6*d.*), by F. G. Harwood (B.R.C.S. and J.A.A.), an epitomised companion to the St. John Ambulance Association Text-book, has just been issued by Messrs. John Bale, Sons and Danielsson, Ltd., and should prove useful to students as a means of summarising knowledge obtained in class and as a text-book for periodical revision. A few hints and suggestions for competition work are added. Another publication by the same author and firm is First Aid for Footballers and other Athletes. This is a 12-page folder, price 3*d.*, which outlines in a few words the treatment for injuries to football players and spectators, and is intended to serve as a reminder for ambulance or Red Cross students. The preface suggests that the folder may be used by "those who accompany teams, but who have not the time or inclination to undertake a complete course of study of this subject." Here we think a word of warning should be added because the instructions are so brief that harm might be done by someone attempting to follow them without previous training. Until the arrival of medical help inaction may be preferable to action, but this only the trained first-aider can know. With this reservation the folder can be recommended.

## SMALL-POX AND VACCINATION IN BIHAR AND ORISSA.

THE report of Lieut.-Colonel W. C. Ross, I.M.S., director of public health in Bihar and Orissa, records a considerable increase in small-pox mortality (0·2 per 1000), as compared with the figure for the previous year. No fatal cases were recorded from Angul district, but in the remaining 20 districts the death-rates varied from 0·01 in Palaman to 0·5 in Puri and 0·6 in Bhagalpur; in the rural districts there was a similar range. Colonel Ross remarks that "vaccination is neither compulsory nor free . . . . it would appear to be wise and proper to organise the work more effectively, and to make vaccination compulsory and free, in order to get the whole population protected, and thus abolish a disease which is, of all diseases, the most easily and cheaply preventable. The manufacturer of vaccine lymph and the organisation of staff for vaccination work are all at present arranged by Government, and facilities are available throughout the province for getting the operation performed by trained vaccinators with pure vaccine." In the resolution of the Ministry of Self-Government for the province dated Oct. 10th, 1925, which follows the public health report, it is stated that "the advantages of vaccination are not adequately realised, and the law only makes vaccination compulsory, not revaccination. Government can only hope that experience will dispel popular prejudice on this subject." The policy of "wait and see" is frequently the best, and, indeed, the only one that is practicable; it would seem, however, hardly appropriate in the present instance.

In a further report on vaccination, also presented by Colonel Ross, it is stated that 1,044,282 operations were performed "during the year 1924–25" (by which is apparently meant the 12 months ending March 31st, 1925); 990,571 were primary operations and 40,575 revaccinations; 97·42 per cent. were successful. Colonel Ross does not consider that small-pox can be effectively dealt with and stamped out unless vaccination is made compulsory throughout the province, and recommends "that the Vaccination Act should be modified so as to extend the age, within which vaccination is required, to 1 year, and should be generally enforced; that vaccination should be free, and that the supervision and control should be delegated to district boards and municipalities and their health officers." Experimental work in regard to loss of potency has established that "this is invariably associated with a development of an acid reaction in the vaccine. It was found that the quantity of pulp obtained was larger, and that the vaccine was potent when fresh, but developed an acid reaction more rapidly, even in cold storage, and became inert in a very short time when exposed to room temperature in warm weather."

# The Oliver-Sharpey Lectures
ON
# CARBOHYDRATE METABOLISM IN HEALTH AND DISEASE.

*Delivered before the Royal College of Physicians of London on May 4th, 1926,*

By HUGH MacLEAN, M.D. Aberd., D.Sc. Lond., M.R C P Lond,
PROFESSOR OF MEDICINE, UNIVERSITY OF LONDON; DIRECTOR, CLINICAL MEDICINE UNIT, ST. THOMAS'S HOSPITAL.

## LECTURE I.*

The subject of carbohydrate metabolism is of special interest, both from the point of view of the biological chemist and the physician. While the particular steps constituting the normal mechanism are of greater interest to the chemist, the breakdown of this mechanism gives rise to symptoms which are the special province of the clinician. It is chiefly from the clinical point of view that I wish to discuss the subject at present, but in order to get as clear an outlook as possible, it is necessary to mention briefly the present views on the fate of carbohydrate in the normal individual.

### Carbohydrate Metabolism in Health.

Under ordinary circumstances by far the greater part of our food consists of carbohydrate material taken in the form of starch. Whatever the nature of the starch may be, it is very quickly broken down in the gastro-intestinal tract and changed into glucose. As glucose it is absorbed into the circulation, to be finally oxidised and excreted in the form of carbon dioxide and water. In the healthy individual quite enormous amounts of starch can be ingested without any sugar being excreted in the urine. In some cases as much as 400 g. or more of glucose can be taken at one time without producing a trace of glycosuria, while the quantity of starch that can be ingested is very great indeed.

It is obvious that the normal body is exceedingly effective in dealing with carbohydrate, and that it is only when disease supervenes that any evidence of the excretion of ingested sugar is obtained. Of the various changes which sugar undergoes in the body we are more or less ignorant, and many of our present views are merely conjecture. Within recent years, however, some little light has been thrown on the subject, and though our knowledge is still very fragmentary and inconclusive, yet some very suggestive observations have been made. It is a curious fact that no matter how much carbohydrate is eaten, the amount of sugar in the general circulation is not increased except quite temporarily. Since sugar is utilised in the body and rapidly disappears as such from the tissues very soon after being taken, it is obvious that sugar must either be quickly converted into some other substance or that it must be equally rapidly destroyed as the result of the normal processes of oxidation.

### *Conversion of Sugar into some other Substance in the Tissues*

*Glycogen and Fat.*—It is well recognised that a large amount of the sugar ingested is stored in the body as glycogen. This storage takes place chiefly in the liver, but comparatively large amounts of glycogen are also found in the muscles. This glycogen-supply serves as a reservoir for the giving out of glucose when it is required for metabolism. That feeding with carbohydrate results in the formation of fat has been recognised for a very long time, but the general impression appears to be that this transformation of sugar to fat is a very slow one. All the available evidence points to the conclusion that once fat is formed it cannot be reconverted into sugar.

*Hexose-diphosphate.*—Many years ago Harden and Young showed that a combination of sugar with phosphoric acid was formed during the fermentation of sugar by yeast. Examination of this compound showed that it contained two molecules of phosphoric acid combined with one molecule of sugar.

$$\left.\begin{array}{l}\text{Phosphoric acid}\\ \text{Phosphoric acid}\end{array}\right\rangle \text{Sugar (hexose).}$$

The sugar obtained on hydrolysis of this compound was found to give the reactions of fructose. The importance of this phosphoric ester in the fermentation of sugar by yeast has been well recognised for a long time, but work carried out during the past few years has sufficed to establish the fact that in the metabolic processes of the muscle cell the formation of hexose-phosphate plays a no less important part. The detection of this substance in the animal organism is based on the work of Embden and his colleagues, who showed that when the fresh muscle-juice of a dog was left to stand, lactic acid very soon appeared. Naturally, for reasons which will be discussed later, it was thought that this lactic acid was probably formed from pre-existing glycogen or glucose, but it was soon established that no corresponding decrease of carbohydrate accompanied this formation of lactic acid. It was observed, however, that whenever lactic acid was formed, free phosphoric acid appeared, and that the amount of this phosphoric acid bore a very definite relationship to the lactic acid formed. Indeed, for each molecule of lactic acid there was found a molecule of free phosphoric acid. Now this is exactly what might be expected to happen if the mother substance was of the nature of the yeast hexose-diphosphate, for each molecule of hexose would form two molecules of lactic acid, at the same time liberating two molecules of phosphoric acid. It was proved, at any rate, that muscle-juice contained some forerunner of lactic acid other than glucose or glycogen, and to this substance Embden gave the name of *lactacidogen*. Subsequently, this product was isolated and shown to be identical with the hexose-phosphate obtained from yeast-juice by Harden and Young.

All recent work points to the conclusion that this tissue hexose-phosphate plays a most important part as an intermediate product in carbohydrate metabolism, and its formation appears to be an essential step in the breaking down of sugar. Though some suggestions have been made to the contrary, there is no evidence that its presence is necessary for the formation of glycogen from sugar.

### *Oxidation of Sugar.*

In discussing the various probable methods by which sugar might be broken down to its simplest products—carbon dioxide and water—it will be necessary to consider shortly the general structure of glucose. Glucose is a compound containing six carbon atoms; it consists *essentially of a* chain of five alcohol groups united to a terminal aldehyde group—CHO.

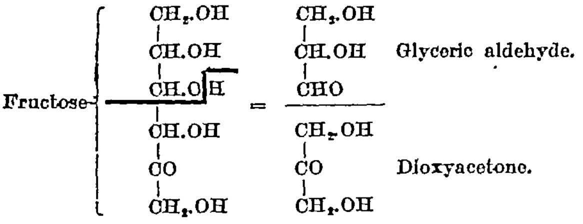
$$CH_2OH-CH.OH-CH.OH-CH\,OH-CH.OH-CHO.$$

All the evidence we possess at present points to the conclusion that during oxidation this six carbon chain splits up into two products, each containing three carbon atoms. It is probable, however, that this happens after the formation of the hexose-phosphate compound already described in which the sugar apparently exists in the *form of fructose*. The split of fructose into two substances, each containing three carbon atoms, is best represented by a cleavage in the position shown in the diagram.

---

* Lecture II. will appear in a subseq t issue.

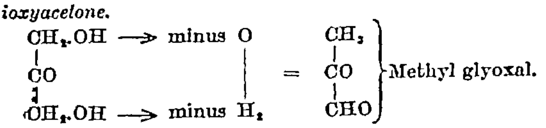
The two substances formed according to this view are glyceric aldehyde and dioxyacetone.



$$\text{Fructose}\left\{\begin{array}{lcll}
\mathrm{CH_2.OH} & & \mathrm{CH_2.OH} & \\
| & & | & \\
\mathrm{CH.OH} & & \mathrm{CH.OH} & \text{Glyceric aldehyde.}\\
| & & | & \\
\mathrm{CH.O|H} & = & \mathrm{CHO} & \\
\hline
| & & | & \\
\mathrm{CH.OH} & & \mathrm{CH_2.OH} & \\
| & & | & \\
\mathrm{CO} & & \mathrm{CO} & \text{Dioxyacetone.}\\
| & & | & \\
\mathrm{CH_2.OH} & & \mathrm{CH_2.OH} &
\end{array}\right.$$

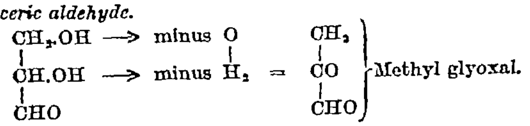
It will be noticed that the empirical formula $(C_3H_6O_3)$ of each of these substances is identical with that of lactic acid, and they can easily be transformed into lactic acid by a simple rearrangement of the atoms. By splitting off the elements of water from either glyceric aldehyde or dioxyacetone, a substance, methyl glyoxal, can be formed in each case, as may be seen from the following equations.

*Dioxyacetone.*



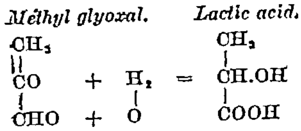
$$\left.\begin{array}{lccl}
\mathrm{CH_2.OH} \longrightarrow \text{minus O} & & & \mathrm{CH_3}\\
| & | & & |\\
\mathrm{CO} & | & = & \mathrm{CO}\\
| & | & & |\\
\mathrm{CH_2.OH} \longrightarrow \text{minus } \mathrm{H_2} & & & \mathrm{CHO}
\end{array}\right\}\text{Methyl glyoxal.}$$

*Glyceric aldehyde.*



$$\left.\begin{array}{lcl}
\mathrm{CH_2.OH} \longrightarrow \text{minus O} & & \mathrm{CH_3}\\
| \qquad\qquad\quad | & & |\\
\mathrm{CH.OH} \longrightarrow \text{minus } \mathrm{H_2} & = & \mathrm{CO}\\
| & & |\\
\mathrm{CHO} & & \mathrm{CHO}
\end{array}\right\}\text{Methyl glyoxal.}$$

By adding on the elements of water in a different manner to methyl glyoxal we arrive at lactic acid.



$$\begin{array}{lcccl}
\textit{Methyl glyoxal.} & & & & \textit{Lactic acid.}\\
\mathrm{CH_3} & & & & \mathrm{CH_3}\\
\| & & & & |\\
\mathrm{CO} & + & \mathrm{H_2} & = & \mathrm{CH.OH}\\
| & & | & & |\\
\mathrm{CHO} & + & \mathrm{O} & & \mathrm{COOH}
\end{array}$$

The above represents a theoretical scheme by which the change from glucose to lactic acid through the intervention of hexose-diphosphate may be represented. It is worthy of note that the various reactions suggested do not involve any oxidation of the original compound. In the classical experiment of Hopkins and Fletcher it was shown that the actual production of lactic acid in muscle was an anaerobic process. It is now necessary to consider what evidence there is that these theoretical changes actually take place in the body.

### *Evidence that such Intermediate Substances may occur in the Body.*

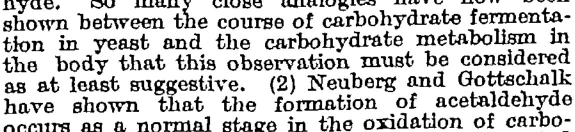
The proof that hexose-phosphate occurs normally in the animal organism has already been given. Convincing evidence was furnished by the experiments of Meyerhof that glucose added to minced muscle is converted into lactic acid *only in the presence of a solution of sodium phosphate.* The fact that the phosphate is essential for this change suggests the view that the formation of hexose-phosphate is a definite and essential link in the chain.

With regard to the probable presence in the animal body of methyl glyoxal, it is significant that an enzyme capable of transforming methyl glyoxal into lactic acid with extraordinary rapidity has been shown to be widely distributed in the tissues by Dakin and Dudley. These observers found that this enzyme was not present in the pancreas, and further made the curious observation that the pancreas contained a substance which inhibited the action of this enzyme. This fact is of some interest when we consider the important rôle played by the pancreas in carbohydrate metabolism. Such is the wonderful [illegible] that a crude aqueous extract of liver containing less than 1 g. of organic matter can form several grammes of lactic acid in the course of a few minutes. Under these circumstances it is obvious that the recovery of methyl glyoxal as such from the tissues could hardly be expected, for it would be immediately converted into lactic acid.

It has been clearly demonstrated by the work of Meyerhof that the glycogen of the tissues is the source from which lactic acid is formed, for according to this author the glycogen in muscle decreases exactly in proportion to the amount of lactic acid produced. A. V. Hill has made the fundamental observation that the heat produced when muscle contracts is evolved almost entirely during the relaxation of the muscle, and is caused by oxidation of a small proportion of the lactic acid produced during contraction, the remainder of the lactic acid being reconverted to glycogen. Apparently, we have, therefore, during muscular activity a reversible series of changes from glycogen to lactic acid and vice versa. In this series of changes hexose-phosphate seems to constitute an essential intermediate stage.

### *Oxidation of Lactic Acid.*

In the light of the above observations it seems fairly certain that lactic acid constitutes a definite intermediate product in the metabolism of sugar. It is known, however, as already indicated, that lactic acid can be completely oxidised in the muscles, and though it is not definitely proved that lactic acid must be always formed before complete oxidation of sugar takes place, yet there seems to be more support for this view than for any other. Until quite recently there was really no evidence as to the nature of the intermediate products derived from lactic acid, but the suggestion was advanced that lactic acid might change into pyruvic acid, and that the latter, by splitting off $CO_2$, might furnish acetaldehyde, which would then be further oxidised to water and carbon dioxide. The following formulæ represent these changes:—

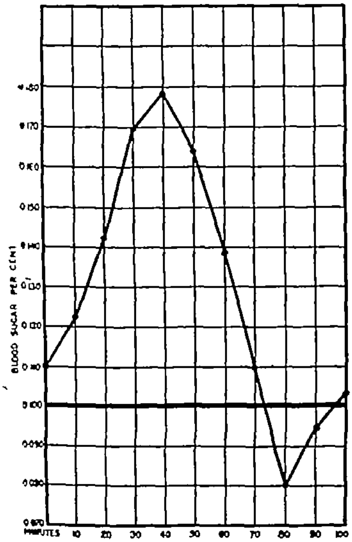


$$\begin{array}{lclcl}
\textit{Lactic acid.} & & \textit{Pyruvic acid.} & & \textit{Acetaldehyde.}\\
\mathrm{CH_3} & & \mathrm{CH_3} & & \mathrm{CH_3}\\
| & & | & & |\\
\mathrm{CH.OH} \longrightarrow \text{minus } \mathrm{H_2} & = & \mathrm{CO} & = & \mathrm{CO}\\
| & & | & & |\\
\mathrm{COOH} & & \mathrm{COOH} \longrightarrow \text{minus } \mathrm{CO_2} & & \mathrm{H}
\end{array}$$

Two pieces of evidence have now been adduced to substantiate this view: (1) Neuberg has demonstrated the presence of an enzyme in yeast which liberates $CO_2$ from pyruvic acid, forming acetaldehyde. So many close analogies have now been shown between the course of carbohydrate fermentation in yeast and the carbohydrate metabolism in the body that this observation must be considered as at least suggestive. (2) Neuberg and Gottschalk have shown that the formation of acetaldehyde occurs as a normal stage in the oxidation of carbohydrate by muscle, and have actually isolated acetaldehyde from the tissues. More than this we cannot say. It is obvious that the gaps in the mechanism of carbohydrate metabolism still require a good deal of filling up, and that a good deal of what has been said above still rests on insufficient evidence. On the whole, however, the work of the last few years has done much to lay more solid foundations on which the future investigator may hope to build with success. The next point to consider is the variations which take place in the blood-sugar of normal and pathological subjects. Without some knowledge of these changes it is quite impossible to appreciate many of the more important facts concerning diabetes and glycosuria.

### THE AMOUNT OF SUGAR IN THE BLOOD.

It is now well recognised that under ordinary circumstances the blood-sugar content varies from time to time. This variation depends chiefly on the ingestion of carbohydrate. Apart from the temporary influence of food, the blood-sugar concentration is wonderfully constant, and in man is roughly about 0·1 per cent. When, however, starch or sugar is taken in sufficient amount, the blood-sugar quickly rises, and in 30 to 45 minutes reaches a maximum value varying from about 0·16 to 0·18 per cent. It matters little whether ordinary glucose or some starchy material is taken. Within a very short period there appears this marked rise in blood-sugar content. This quick response indicates that the hydrolysis of starches in the gastro-intestinal tract must be an exceedingly rapid process. The changes in blood-sugar can be well studied by giving 50 to 60 g. of glucose dissolved in a few ounces of water and estimating the blood-sugar at frequent intervals. Very often the maximum concentration of blood-sugar is reached within 30 minutes after the ingestion of the glucose. From this point onwards the blood-sugar steadily falls, until in an hour or an hour and a half it again regains its normal level of 0·1 per cent. Indeed, not infrequently it actually sinks to a lower level than this, and after remaining at this low level for a short time quickly returns to the normal. Though slight variations of this phenomenon occur in different individuals, the general result is more or less as described. A blood-sugar curve obtained from a healthy individual is represented in the diagram here shown.



A normal blood-sugar curve.

Now it is quite easy to understand why the blood-sugar should rise after taking starch or sugar by mouth. There is an increased absorption of sugar from the intestine into the circulation, and consequently a definite increase in blood-sugar would be expected. It is much more difficult to explain why this rise should be so quickly succeeded by a sudden fall. It might be argued that the bulk of the sugar had already been absorbed when the curve reaches its maximum, and that the fall in blood-sugar was simply an indication of this fact. That this is not the case is obvious for various reasons. It can be shown that when the curve has regained the normal level there may still be plenty of sugar in the stomach, and that absorption may be going on rapidly with the blood-sugar as low as 0·08 per cent. or so. Also, this sudden fall does not take place in the diabetic subject. It is therefore certain that when the curve begins to fall, some mechanism comes into play by which the absorbed sugar is removed from the blood. What is this mechanism? The question is a difficult one, but there are various possibilities. The sugar might be rapidly oxidised by the tissues. No doubt this factor plays a part in reducing the blood-sugar, for experiments show that there is an increase of oxidation of carbohydrate at this stage as indicated by the respiratory quotient rising to 1. It is possible, however, to calculate the maximum amount of sugar that could be destroyed in an individual from the time that sugar is ingested until the blood-sugar returns to normal. It is quite certain that the amount of sugar destroyed during this period accounts for but a small part of the total sugar absorbed. Again, it would be a most wasteful method that would destroy all the sugar immediately on its being absorbed. Indeed, it is very probable that actual destruction of sugar by the tissues plays but a small part in the rapid reduction of blood-sugar after a carbohydrate meal, for there are many patients who show normal powers to oxidise sugar, and yet give a typically abnormal curve.

No doubt gradual dilution of the sugar in the stomach has some effect, for Goldblatt has shown that when 50 or 60 g. of sugar are taken in a litre of water the blood-sugar does not rise to any appreciable extent. If the sugar is not destroyed the only possibility is that it is quickly converted into some other substance and stored as such. This is really what happens. When the blood-sugar reaches a certain concentration a mechanism comes into play which removes the sugar from the blood and stores it in the form of glycogen. This mechanism continues to act until the blood-sugar regains its normal level, however actively the absorption from the intestine is going on. Now it is well known that the chief depôts of glycogen are the muscles and liver. For various reasons it is my opinion that the chief site of this storage is the liver. This statement is based largely on clinical observations which indicate that whenever the liver cells are diseased or abnormal, the reduction of blood-sugar after a carbohydrate meal fails to take place in the usual way, or is very markedly interfered with. There is every reason to suppose that formation of glycogen in the muscles also plays some part, but it appears to be a subordinate one.

What happens therefore when carbohydrate is taken in sufficient amount is that the glucose passing into the liver by the portal system is at first allowed to pass through into the general circulation, but that after a time, when the blood-sugar reaches a certain concentration, the liver begins to hold back the sugar and to store it into the liver cells in the form of glycogen. The result is that the peripheral blood-sugar quickly falls. It is certain that the internal secretion of the pancreas (insulin) must play a definite part in this mechanism, but how it acts is at present far from clear. It might be argued that the initial increased concentration of sugar in the blood acts as a stimulus to the pancreas, and causes it to secrete insulin which is responsible for the phenomenon. There are some difficulties in accepting this view. Lævulose, for instance, is apparently stored in the liver immediately, for it does not raise the blood-sugar concentration. It is therefore difficult to see how this sugar can stimulate the pancreas, since it apparently never enters the general circulation; also it is apparently stored before any stimulation of the pancreas would have time to secrete the necessary insulin. Hewitt has shown that lævulose is more slowly absorbed from the intestine than glucose, but rate of absorption plays practically no part in preventing a rise in blood-sugar, since lævulose causes a marked rise in the diabetic subject.

Since lævulose is immediately changed into glycogen on absorption into the portal system, it is possible that glucose gradually becomes changed into some isomeric substance having a structure closely allied to that of lævulose, and that it is this substance which the liver changes into glycogen. If it is true, as generally claimed, that the sugar of animal hexose-phosphate is lævulose, this fact might lend some support to the above idea.

Some years ago evidence was brought forward in favour of the view that the sugar present in the tissues of the normal individual was really not ordinary glucose, but an isomeric form more reactive than glucose—so-called $\gamma$ glucose. This view has not been confirmed. In this connexion it was shown by Tallermann that the sugar excreted in the urine of the normal individual as the result of phloridzin administration was apparently ordinary glucose. Presumably this sugar passed in the urine must have possessed the same structure as the blood-sugar from which it was derived.

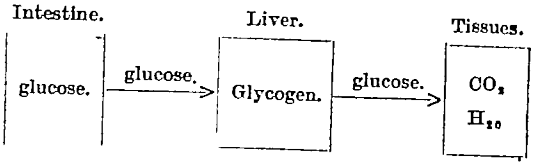
### THE RENAL THRESHOLD FOR SUGAR.

In ordinary circumstances practically no sugar passes from the blood into the urine as long as the blood-sugar concentration remains below a certain figure. In the average individual the kidney begins to let sugar pass whenever the blood-sugar content rises to 0·18 per cent. or so. It is an interesting fact that it is practically impossible in health to raise the blood-sugar to this point however much sugar or starch is eaten. Whenever the blood-sugar begins to approach this so-called threshold line the storage mechanism above described comes into action and prevents the sugar from reaching the critical point. But since no excretion of sugar by the kidneys takes place until the threshold is exceeded, it follows that glycosuria can only be produced with the very greatest difficulty, if at all, in the perfectly normal individual. There is really no such condition as the "alimentary glycosuria" of the text-books. Generally speaking, it does not matter how much sugar is absorbed, for the normal liver is capable of dealing with very large amounts, and so prevents the blood-sugar from rising sufficiently high to overflow into the urine. From this it is obvious that under ordinary circumstances, when a patient has glycosuria, his blood-sugar must at any rate be as high as 0·18 per cent.

In some subjects this threshold is placed at a much lower level, and occasionally it may even be below the normal blood-sugar value of 0·1 per cent. In these cases sugar passes into the urine whenever the blood-sugar rises to the concentration constituting the altered threshold. In other words, sugar leaks through the kidney constituting the condition known as *renal glycosuria*. This abnormality, which is now recognised to be so important from the clinical standpoint, will be discussed later. From this brief discussion of the changes which normally take place in blood-sugar concentration we may now pass on to a consideration of diabetes.

### "DIABETES."

Though one of the most striking features of diabetes is the presence of sugar in the urine, it must not be forgotten that diabetes indicates a breakdown in the metabolism not only of sugar, but of protein and fat as well. Unfortunately, in clinical work the term *diabetes* is used to include at least two entirely different conditions with the result that much confusion prevails. It is often stated that diabetes in the young is a much more serious condition than diabetes in the middle aged and elderly. This, however, does not appear to be strictly true. Typical diabetes is equally severe at whatever age it appears. How, then, are we to account for the well-known clinical fact that many elderly patients may pass sugar in the urine for years without any ill-effects, while glycosuria in the young is a much more severe malady? The answer seems to be that this chronic glycosuria of the elderly subject is not really diabetes at all. To understand the position fully it will now be necessary to consider the mechanism by which glycosuria is produced. When sugar is absorbed from the intestine it first passes into the liver and, as already shown, it is to a large extent stored there in the form of glycogen. When required the glycogen is reconverted into sugar and is ultimately oxidised by the body tissues. These points are indicated in the diagram.



Now it is obvious that marked glycosuria might be caused by (1) failure of the liver to convert the absorbed sugar into glycogen, or (2) failure on the part of the tissues to oxidise sugar. Either or both of these factors acting together would result in a marked hyperglycæmia with consequent glycosuria. In true diabetes, definite evidence of defective oxidation can easily be obtained. Thus ingestion of sugar in the diabetic subject does not generally cause an increase in the respiratory quotient such as is observed in the normal individual. Again, the diabetic subject shows evidence of defective fat oxidation as indicated by the presence of ketone bodies in the urine. In many elderly individuals with very marked glycosuria no evidence of defective oxidation of either sugar or fat can be obtained. No ketone bodies, or at most only traces of these substances, are present in the urine. These points indicate that there must be some fundamental difference between the glycosuria of the elderly individual and true diabetes. What is this difference? Many observations point very strongly to the view that this chronic glycosuria is largely dependent on the inability of the individual to store sugar in the liver. This results in an increase of sugar passing into the blood and giving rise to glycosuria. It seems certain that the power to store sugar may be very largely lost, while the power to oxidise sugar may be apparently quite efficient, and it is this lack of power to store that accounts for the so-called chronic diabetes of the elderly subject. This conception explains many puzzling clinical features such as the lack of definite symptoms so often observed. Nutrition is well maintained, and though the condition is generally called diabetes, it should really be differentiated from true diabetes.

### *Cause of Defect in Storage.*

Everybody is now agreed that normal carbohydrate metabolism is dependent on the secretion of insulin by the pancreas, and the wonderful effects of insulin in the treatment of diabetes lend ample support to this view. There seems no doubt whatever that true diabetes arises from a disturbance in the pancreas resulting in an insufficient supply of insulin to the organism. On casual consideration we might suppose that lack of storage of sugar is also necessarily connected with some pancreatic defect, but this is by no means quite clear. If defective storage were always due entirely to an insufficient supply of insulin, it is strange that patients showing marked glycosuria and with very little power to store sugar, frequently go on for years and years without showing any evidence whatever of the slightest defect in oxidation. It might be thought that in severe cases of this type of glycosuria some evidence of definite oxidation would be obtained if storage and oxidation of sugar were entirely dependent on the same factor. The clinical evidence, indeed, strongly supports the view that whatever part the pancreas may play, there is another factor present which is of very great importance. This factor seems to be connected with some change in the liver. At present our thoughts and ideas are so centred on insulin that we are liable to forget that the metabolism of sugar in the body requires not only insulin, but a specially organised tissue through which insulin acts. Insulin alone will neither oxidise sugar nor convert it into glycogen;

another factor is necessary which is inherent in the tissue itself. Now it is very probable that under certain circumstances the tissue cells may lose, to some extent, their power to form glycogen, even when the normal amount of pancreatic secretion is available. It is a striking clinical fact which has been noted again and again, that the glycosuria of the elderly subject is very frequently associated with some pathological changes in the liver. I am not unmindful of the fact that such hepatic changes may often be associated with pancreatic changes as well, but, for the reasons already given, pancreatic changes by themselves hardly account for the condition. The most reasonable view to take, in the light of our present knowledge, is that the so-called chronic diabetes of the elderly subject is associated with some changes in the liver, and that whatever part the pancreas plays in this connexion, a pancreatic lesion is not the sole and probably not the most important factor. The condition generally referred to clinically as diabetes may therefore be classified under two types: (1) hepatic glycosuria (the chronic diabetes of the elderly subject), and (2) true diabetes.

### *Hepatic Glycosuria of Elderly Subjects.*

Though the glycosuria present in this condition is often very marked and intensive, it frequently happens that practically no other symptoms are found. When the malady has persisted for a considerable period, certain symptoms frequently appear, but they are usually of a somewhat different nature from those associated with typical diabetes. Thus, there is little or no acidosis and no tendency to coma. Not only is nutrition in general well preserved, but patients are often abnormally fat. Sometimes, however, the large loss of sugar results in some decrease of weight. In this type of case the symptoms that may arise appear to be definitely dependent on the excessive amount of sugar in the blood.

The most important results of this hyperglycæmia are: (1) local irritation; (2) cramps and pains in the joints; (3) neuritis; (4) eye changes; and (5) general weakness and mental irritability. Of all these symptoms, local irritation produces, perhaps, the greatest discomfort, especially in women. The continued irritation sometimes experienced is so intense that patients have been known to commit suicide. Cramps and pains are often very troublesome, and may be so severe as to be mistaken for the pains of locomotor ataxy. In all cases, therefore, in which severe pains of doubtful origin are present it is well to examine the urine. Neuritis is, unfortunately, very common. Eye changes may be so extensive as to lead to actual blindness, and general muscular weakness may be well marked. It is safe to say that none of these symptoms can be ameliorated unless steps are taken to reduce the excessive blood-sugar. When this is done it is wonderful how some of these ailments disappear in a comparatively short time. I have known a patient who had suffered with very severe pains in his legs and shoulders for over two years, and, who for some weeks before treatment, was reduced to a pitiable state owing to suffering and lack of rest at night. On giving him a suitable diet all the pains entirely disappeared within ten days. The result of treatment is not always so dramatic as this, but perseverance generally has its reward in these cases. The onset of eye symptoms always suggests immediate and persistent treatment.

### *Prognosis in Hepatic Glycosuria of the Elderly.*

Very often the condition goes on for 20 years or more without getting much worse, and the patient dies of some other disease. Frequently, after a certain number of years, some of the symptoms just mentioned develop to such an extent that definite treatment becomes necessary. In a few cases, after many years of harmless glycosuria, the patient more or less suddenly develops the usual symptoms of typical diabetes. He wastes rapidly and loses weight; the urine, which was formerly free from ketone bodies, now contains large amounts of acetone with diacetic and oxybutyric acids; his condition becomes grave and coma threatens.

How are we to explain this sudden change? I think that the most rational view is that the persistent hyperglycæmia had after many years worn out the pancreatic islet tissue with the result that the necessary amount of insulin ceased to be secreted. It has been abundantly proved by the work of Allen that continued high blood-sugar tends to exhaust the pancreas and cause diabetes. In these cases of prolonged glycosuria in the elderly, the wonder is that the pancreas is not worn out more frequently than is actually the case. The fact that marked hyperglycæmia continuing for many years does not usually exhaust the pancreas to the point at which ordinary diabetes supervenes, seems to me to be another proof that a primary pancreatic defect is not the chief factor in this form of diabetes. Indeed, it might be argued that in these cases the special islets of the pancreas are particularly healthy to begin with, and therefore very resistant to the detrimental effects of hyperglycæmia.

If we remember the above distinctions between the diabetes of the elderly individual and true diabetes, it helps us to get a rational view of the position. When true diabetes occurs it is as acute in the elderly as it is in the young, but since true diabetes is probably always associated with a pancreatic defect, its development must often mean that the pancreatic islets were fundamentally weaker than normal to begin with. Naturally, such weakness would be likely to show itself in youth; if a subject lives to an advanced age without showing any evidence of diabetes, this, of itself, signifies that he must have inherited a sound pancreas. Any defect would almost certainly have been found out early in life. It is thus obvious that true diabetes is more likely to develop in the young, while diabetes at the other end of the scale is more likely to show itself after a considerable strain on the pancreas from hyperglycæmia. The glycosurias of the elderly are not diabetic at all, and in the light of what has been said there is no reason to believe that true diabetes is not equally severe at all ages.

In the next lecture I shall discuss renal and other forms of glycosuria, acidosis, the diagnosis of diabetes, diet in diabetes, and some experiences with insulin.

WELLCOME HISTORICAL MEDICAL MUSEUM.—The Museum at 54A, Wigmore-street, W., was partially reopened on June 1st, but the work of reorganisation is still proceeding with a view of making the collections more accessible for inspection and study. The museum is open to members of the medical profession, chemists, pharmacists, nurses, and research workers generally from 10 A.M. to 5 P.M. on week days, Saturdays 10 A.M. to 1 P.M.

RAILWAY CONCESSIONS TO CZECHO-SLOVAKIAN SPAS.—Visitors to the various Czecho-Slovakian spas and health resorts will be granted a special reduction of 50 per cent. on the cost of their railway journeys within the Czecho-Slovak Republic. In order to secure this concession, which supersedes all previous arrangements of this kind, visitors must remain for at least ten days in any one spa, where they should apply to the spa administration before starting on their return journey.

# Presidential Address

ON THE

# PRESENT POSITION OF CHLOROFORM.

*Delivered before the Scottish Society of Anæsthetists at Dundee*

BY ARTHUR MILLS, M.D. ST. AND.,

LECTURER IN ANÆSTHETICS, UNIVERSITY OF ST. ANDREWS;
INSTRUCTOR IN ANÆSTHETICS, DUNDEE ROYAL INFIRMARY;
HON. ANÆSTHETIST, DUNDEE ROYAL INFIRMARY
AND DUNDEE DENTAL HOSPITAL.

DOUBTLESS we have been slow in this district to accept the view that the administration of anæsthetics is work requiring special skill and experience, for it is only within very recent times that the staff of anæsthetists in our hospital has been adequately increased. There are now six anæsthetists, a number sufficient to overtake practically all the work that is being done. I fear, however, that a long time may yet lapse before there will be a like demand for the services of the anæsthetist in private practice. Strange as it may seem, many a doctor still holds the opinion that "anyone can give chloroform." The economic factor, too, is, I fear, strong enough to perpetuate the old custom, and we may accept the fact that for some time to come many private patients will be anæsthetised by comparatively inexperienced administrators. It is with this fact constantly in mind that I have framed the views and opinions which I am about to express.

## CONFLICTING VIEWS AS TO CHLOROFORM.

Frequently in the past the value of chloroform as an anæsthetic has been discussed. In 1919 Dr. Paton Boyd took this subject for his presidential address and severely criticised the extreme attitude of the American anæsthetists. The Committee of Anæsthesia of the American Medical Association reported in 1912 that the use of chloroform was no longer justifiable, and that its use for minor operations should cease, but that it was sometimes of convenience for inducing anæsthesia in alcoholics or in difficult cases. In some places it would appear that chloroform has been entirely discarded. During 1923 17,813 anæsthesias were administered at the Mayo Clinic, and chloroform was not used on a single occasion.

Are we prepared to define clearly our own views on this important subject? When that report was issued by the American Medical Association in 1912 chloroform was practically the only anæsthetic used in Dundee and the surrounding district for all ordinary operations; indeed, we were not asked to give an anæsthetic, we were asked to "give chloroform." Though many practitioners now realise that there are certain limitations to the use of chloroform, and that other and safer anæsthetics are available, others persist in the belief that, provided with nothing but chloroform, they are justified in proceeding to induce and maintain anæsthesia wherever and whenever general anæsthesia is required. Chloroform deaths thus still take place, and by "chloroform death" I mean a very definite form of fatality. I suggest that our knowledge of the pharmacological action of chloroform and other anæsthetic drugs is now such that these deaths are avoidable, and that we as teachers of anæsthetics are responsible for inculcating better and safer methods. Such methods, however, must be simple, and not associated with the use of complicated apparatus, if they are to be adopted by the practitioner desirous of giving an anæsthetic only when the necessity arises in his own practice. Some such simple method I shall attempt to describe, but before doing so I should like to discuss briefly the manifest contra-indications to the use of chloroform.

## CONTRA-INDICATIONS TO THE USE OF CHLOROFORM.

Chloroform, of course, possesses certain obvious advantages. It is a powerful anæsthetic and easy to administer. A few cubic centimetres of chloroform administered on a towel or piece of lint are sufficient to produce anæsthesia. It is non-irritating to the respiratory passages and is pleasant to inhale. It produces a quiet type of anæsthesia and no undue congestion of the incised parts.

The dangerous effects of chloroform fall into four groups: (1) depression of the respiratory centre; (2) fall in the blood pressure; (3) late toxic effects—delayed chloroform poisoning; (4) chloroform syncope—death occurring very suddenly, usually, but not invariably, in the stage of induction.

I have not mentioned these groups in the order of their importance, the most important one being group 4, which I should prefer to discuss last.

(1) Chloroform has a depressant effect upon the respiratory centre. It dulls this centre's sensitivity to its normal stimulus from carbon dioxide. During anæsthesia the amount of carbon dioxide produced in the body is considerably reduced, and if at the same time the centre become less sensitive a condition of anoxæmia may result from deficient ventilation of the lungs. This danger is further increased by the fact that chloroform also reduces the oxygen-carrying capacity of the red corpuscles. Depression of the respiratory centre is usually of gradual onset and manifests itself in an unmistakable manner. The careful and observant administrator rarely permits the condition to become serious. Moreover, depression of the respiratory centre is not an effect peculiar to chloroform. The other anæsthetic agents have a similar action, but in less degree. It cannot thus be regarded as a factor of sufficient importance entirely to contra-indicate the use of chloroform.

(2) Chloroform in full anæsthetic doses causes a fall in blood pressure, and this fall is roughly proportionate to the depth of anæsthesia reached. The low blood pressure resulting from chloroform anæsthesia is similar in nature to that of surgical shock. It is not due to failure of peripheral resistance, for the arterioles are in a state of constriction. It is due to an imperfect filling of the heart in diastole and consequent diminished output into the arterial circulation with a stagnation of blood in the splanchnic area and in the capillaries. A tame rabbit suspended by the ears passes into a state of shock and dies. This condition of gravity shock is much more easily produced in the chloroformed animal than in the animal which has not been chloroformed, and is the more easily produced the more deeply the animal is anæsthetised. It has been shown that quantities of histamine too small to produce any effect upon a normal animal cause a marked fall of blood pressure when injected into an animal after prolonged chloroform anæsthesia. The histamine-like bodies produced when tissues are injured are believed to be the chief cause of shock, so that this action of chloroform in increasing the susceptibility of the tissues to histamine will also account for its predisposing to shock. Chloroform is thus strongly contra-indicated in cases where the patient is already suffering from a low blood pressure. In this respect patients suffering from shock or who are in a gravely debilitated condition are unsuitable subjects for chloroform anæsthesia.

(3) Post-anæsthetic toxæmia may follow the administration of any anæsthetic, but is much more frequent after chloroform. The condition is also known as delayed chloroform poisoning, and its symptoms are familiar to all of us. It is much more common in children than in adults, and toxæmia and starvation are powerful predisposing factors. It is a condition of acid intoxication comparable to that met with in diabetes, salicylate poisoning, and recurrent or cyclic vomiting. Acidosis or acid intoxication is due to the presence in the circulation of an abnormal amount of substances of the acetone group, and this excess may be due to too rapid formation or to too slow elimination,

or to both. Acetone bodies are the result of increased fat metabolism, which again is a result of the diminution in the carbohydrate metabolism. Elimination is performed by liver and kidneys, and deficient elimination results from damage to liver and kidney cells. Starvation and constipation and anæsthesia increase fat metabolism and increase acetonæmia. Septic absorption and chloroform damage liver and kidney cells. Clinically we find that the child who is suffering from a septic abdomen and who has had little or no food for a few days prior to operation is the most susceptible of all patients to post-anæsthetic acidosis. Chloroform is absolutely contra-indicated in these cases. It is also contra-indicated in the case of children known to suffer from cyclic vomiting. Such children may have a severe and fatal attack precipitated by a very short administration of chloroform. There is no evidence that chloroform produces an increased acetonæmia more readily than does ether. In this respect anæsthesia and asphyxial conditions are closely related. There is, however, strong evidence that chloroform, by its toxic effect on the liver and kidney cells, is much more dangerous than ether, and the acetonæmia produced is maintained and aggravated through deficient elimination. Beely, in 1906, referring to work in the Children's Hospital in Edinburgh, reported that "out of 10 cases of acute appendicitis operated on under chloroform 14 died; out of 24 cases operated on under ether only 2 died, and that not as the result of acid intoxication."

### DANGERS DURING THE INDUCTION PERIOD.

(4) The large majority of chloroform deaths (80 per cent. or more) take place during the induction period. The victim is not infrequently a robust adult male. As an example of what may be regarded as a typical chloroform death, I quote the following case:—

> The patient was an ex-soldier, 53 years of age, who had had 30 years service abroad. He was of spare muscular frame, arteries hard, chest somewhat emphysematous and rigid, heart sounds could only be faintly heard, but his general condition was good. The operation intended was stretching the sciatic nerve. Anæsthesia was induced with chloroform on an open mask. The stage of excitement was very prolonged with violent struggling, spasm of the muscles, irregular respiration, and some cyanosis. Suddenly there was general muscular relaxation and the breathing lost its spasmodic character. The anæsthetic was at once withdrawn. Then followed a few deep regular respirations, but the breathing soon became shallow and stopped, the pupils being widely dilated and the complexion of a livid hue. No pulse could be felt at the wrist and the heart sounds were inaudible. Attempts to resuscitate the patient failed.

It is obvious that the patient's heart had suddenly ceased to beat and respiration only stopped after the respiratory centre had failed from want of blood.

I believe that I am correct in stating that a similar sequence of events never takes place when ether is the anæsthetic employed. Of a series of 33 chloroform deaths which I have investigated I find that at least 21 were of this nature. Such deaths are due entirely to the misuse of chloroform, and should cease to take place if our teaching is sound and is honestly followed. Of the several rival theories advanced to account for these sudden chloroform deaths, two only appear to me to be of value and to be more or less supported by clinical experience. Violent excitement in the induction stage will be admitted by all to be a frequent precursor to a catastrophe. In the series of cases investigated this state of excitement was emphasised in the report in 12 out of the 21, and may, of course, have occurred in others. Pohl found in a dog which had been killed by a few breaths of concentrated chloroform vapour that the blood in the left ventricle contained 0·2 per cent. chloroform, whilst that in the right ventricle contained only 0·02 per cent. He suggested, therefore, that in many cases death was caused as follows. During the stage of excitement and irregular spasmodic respiration the patient first held his breath and allowed chloroform vapour to accumulate under the mask; then he took a deep breath inhaling a concentrated chloroform vapour which passed into the blood and went direct to the heart and coronary arteries. In this way a toxic action upon the heart was produced long before the other tissues of the body were saturated with the drug. This theory would appear to fit in with a number of reported cases and could reasonably be applied to 12 or more of my series of 21. Levy, on the other hand, maintains that this theory has no experimental support, and states that high percentages of chloroform administered to animals are incapable of producing sudden stoppage of the heart. The matter would appear to require further investigation.

### VENTRICULAR FIBRILLATION AS A CAUSE OF CHLOROFORM DEATH.

In 1889 MacWilliam brought forward a new view as to the causation of sudden death by a previously unrecognised form of failure of the heart's action—namely, a condition of sudden ventricular fibrillation. It would appear to be not only a common cause, but the usual cause of sudden and unexpected death of cardiac origin, such as we meet with in cases of angina pectoris, sometimes after operations, and frequently where no pathological condition was suspected, but the individual is engaged in some form of violent exercise. Such deaths also frequently accompany or follow some emotional state. Ordinary cardiac or myocardial failure is a progressive exhaustion of the contractile power of the cardiac muscle and death is then by no means sudden. Sudden loss of contractile power does not occur. When ventricular fibrillation supervenes, on the other hand, we have a sudden disastrous change occurring in a cardiac muscle that may have been showing no symptoms of ordinary cardiac failure. There is an abrupt replacement of the effective systole by a continuous incoördinated activity in the muscular fasciculi, so that some are contracted and others relaxed, the result being a mere quivering of the ventricular walls with complete loss of any expulsive power. The result to the organism is the same as that of absolute stoppage of the heart's action. Unlike auricular fibrillation ventricular fibrillation is promptly fatal.

As the exciting cause of this condition MacWilliam emphasises muscular exertion, and especially when associated with emotional excitement. Sudden deaths of this nature take place during or very shortly after exertion. Muscular effort involves an increased demand upon the heart. Emotional excitement does the same. The amount of work that the heart is called upon to do per minute is enormously increased. There is an increased force and frequency of the heart beat, and the blood pressure is raised, giving a greater resistance. Conditions producing a susceptibility to ventricular fibrillation are tabulated by MacWilliam as follows: Altered nutritive conditions in the heart muscle as in coronary obstruction; toxic agencies such as typhoid fever and diphtheria; certain chemicals such as digitalis, barium salts, many other chemical compounds, and chloroform. The relation of chloroform anæsthesia and susceptibility to ventricular fibrillation has been worked out both by MacWilliam and by Levy, more particularly by the latter, and on the main points these two workers are in practical agreement. They have demonstrated that in healthy animals, cats particularly, a great susceptibility to ventricular fibrillation may be established by the administration of chloroform. Chloroform produces the state of susceptibility, and fibrillation is then easily produced by various forms of stimulation of the heart. Levy further insists that light anæsthesia is an essential condition, and that under deep anæsthesia a fatal result cannot be obtained. The forms of stimulation that produce fibrillation are: cutting the vagal trunks in the neck, the injection of one minim of 1 in 1000 adrenalin into a vein, direct excitation of the sympathetic nerve-supply of the heart, the stellate ganglion or the accelerator nerve, and stimulation of the cut ends of sensory nerves. Extreme deprivation of oxygen may have a similar effect. Furthermore, ventricular fibrillation may be initiated during a fit of struggling in a cat under light chloroform anæsthesia, comparable in all respects to the familiar stage of excitement and struggling in the human subject.

Levy constantly lays emphasis on the lightness of the anæsthesia which is required in these experiments, and insists that the heart is more susceptible under light chloroform anæsthesia than under deep anæsthesia. It is difficult to believe that a low percentage of chloroform in the blood can do more harm to the heart than a higher percentage. To produce the state of ventricular fibrillation it is evident that there must first be a condition of susceptibility and then an exciting cause. May it not be possible that in deep chloroform anæsthesia the heart is more susceptible but the exciting cause is absent? We know that chloroform is a powerful cardiac depressant, and that in every case where it is administered the contractile power of the heart is weakened and its walls dilate. A call upon the heart under these conditions to beat with greater force and frequency means an enormous extra strain, for the force required to empty its ventricles increases as the cube of the radius. Stimulation might thus only excite fibrillation if that stimulation succeeded in producing an effort on the part of the weakened heart to beat with greater force and frequency. If the anæsthesia be deep it is conceivable that excitability of the heart would be so depressed with chloroform that it would make no effort in response to a stimulus, and the fatal disturbance to its action would not then take place. Levy's work is interesting, and I think of great value, but his manner of application of his results to practical anæsthetics is unfortunate. His teaching is entirely at variance with clinical experience. He constantly emphasises the danger of light chloroform anæsthesia, yet he does not define what he means by "light chloroform anæsthesia." The use of the expression "death due to light chloroform anæsthesia" is in my opinion unjustifiable. It conveys, moreover, the wholly false and dangerous doctrine that safety would have been found in giving more chloroform.

One must admit on study of the writings of these two workers that they have established strong evidence in favour of ventricular fibrillation being the cause of these sudden chloroform deaths. One must also conclude, however, that Levy's or, indeed, anyone's "principles of the safe administration of chloroform" are futile, and that it is quite impossible with our present knowledge always to render safe the administration of this drug.

I take it, therefore, that our teaching must be that the use of chloroform as an anæsthetic agent is not justifiable: (1) In cases of grave debility with low blood pressure, and more particularly in cases where the patient is suffering from shock. (2) In cases likely to develop acidosis, the most susceptible being the diabetic, the sufferer from the septic abdomen (the more especially if the patient be a child), and children who are the subjects of cyclic vomiting. (3) In a great many cases during the induction period.

Unlike our friends in America, I would not countenance its use during the induction period in alcoholics and difficult cases. Alcoholics and difficult cases are just those cases where a fatal result is to be looked for if chloroform be so employed. We must deal with our alcoholics and our difficulties in some other way. We must impress upon our students that to continue to administer chloroform to an excited and struggling patient cannot be made a safe proceeding, and that it is unnecessary, and therefore unjustifiable. We must teach our students other and safer methods.

### A Simple Method for General Use.

Possibly cases of labour offer the one exception to a rule which I believe should be strictly adhered to, and that rule is—that no one should proceed to produce full surgical anæsthesia supplied only with the means of administering chloroform. As a routine method suitable for the general practitioner and house surgeon to use, and combining simplicity with safety, I advocate induction with the drop bottle and mask, and as a minimum of equipment, the administrator must be provided with chloroform and chloroform mask, ether and ether mask, a container of ethyl chloride of the type for general anæsthesia, and the usual tongue forceps, prop, and so forth. As we have seen, cases will be met with where chloroform is absolutely contra-indicated at any period in the administration. He should therefore be able to induce and maintain anæsthesia with ether alone by the open method, and should understand the value of previous medication with atropine and morphine. When not so contra-indicated chloroform can be administered with advantage up to the second stage, a change being made to the ether mask and ether as soon as the first sign has appeared that the stage of excitement has been reached. Full anæsthesia must be induced now with ether, aided, if necessary, by the addition of a little ethyl chloride on the ether mask. Chloroform must not be resumed till full anæsthesia has been reached, and only then if the nature of the operation favours a chloroform anæsthesia. The administrator will in the induction period frequently find it advantageous to change from chloroform to ether before the stage of excitement has been reached; he must never be tempted to delay the change after that stage has been reached. I do not hesitate to recommend this method, and for the following reason: its simplicity is obvious, and no cumbersome or perishable apparatus is required. I have never observed any alarming effects to accompany the administration of chloroform in a dilute and gradually strengthened vapour up to the stage indicated. Such a procedure has much to be said in its favour. Chloroform is a more pleasant vapour than ether to inhale. The sense of smell is quickly lost and the upper respiratory passages soon become dulled and less sensitive to the irritating effects of the pungent ether vapour which is to follow. In this way we eliminate a distressful experience for the patient, and we frequently avoid the coughing and salivation which are so prone to accompany the earliest stages of induction with ether. The safety of this method has been confirmed to my satisfaction over a period of eight years, comprising about 25,000 administrations.

### Mortality Statistics.

I have studied the reports of deaths under an anæsthetic occurring in the Dundee Royal Infirmary from 1904 to the end of 1923. I chose this period because 1904 appears to have been the first year that records were preserved, and the end of 1923 marks the end of that period when anæsthetics were given very largely by the house surgeons. Thereafter the staff of anæsthetists was very much augmented, and the records accordingly cease to have the same significance. The results of this investigation not only confirm the views which I have expressed, but justify me in continuing to inculcate the doctrines which I have laid down. From 1904 to 1916, when full induction with chloroform was the rule, the death-rate was 1 in 910 cases. From 1917 to 1923, when the methods I have described were largely followed, the death-rate was 1 in 7400 cases. Moreover, the deaths occurring in this latter period, three in number, would probably have been avoided had the administrator been able to proceed according to the newer teaching.

The reports number 43. In 10 cases the report definitely stated that death was due to some cause other than the anæsthetic. In several instances this was undoubtedly the case, as, for example, when death took place from hæmorrhage from the superior longitudinal sinus. In others the opinion was not so apparently well founded. When it was stated, for example, that death was not due to the anæsthetic but to the shock of the operation, and chloroform was the anæsthetic in use, one feels inclined to attribute to the anæsthetic some share, at least, in the production of the state of shock. In the majority of these 10 cases it was, however, obvious that the patient was moribund before the anæsthetic was administered. We are thus left with a series of 33 cases where, according to the report, death was due to the anæsthetic. Chloroform was the anæsthetic in 20, and a mixture of chloroform and ether in 4. Twenty-one were due to chloroform syncope in the stage of induction, the occurrence of excitement and struggling being emphasised in 17 of these. In 2 cases the Vernon Harcourt inhaler was being used; 5 were due to chloroform syncope during the operation; 4 were due to chloroform producing or contributing to a state of shock. The anæmic condition of the patient previous to operation was emphasised in three reports. Three reports were much too vague to permit of forming a definite opinion. In no case could death be attributed to a pure depression and final arrest of the respiratory centre. No statistics regarding delayed chloroform poisoning could be obtained.

In arranging my facts concerning the pharmacological action of chloroform I have borrowed freely from the following works: MacLeod's "Physiology and Biochemistry in Modern Medicine," Clark's "Applied Pharmacology," Levy's "Chloroform Anæsthesia," and Hewitt's "Anæsthetics and their Administration."

# THE PATHOLOGICAL ACTION OF LIGHT UPON THE EYE.

BY W. STEWART DUKE-ELDER, B.Sc.,
M.D. ST. AND., F.R.C.S. ENG.,
PLIMMER RESEARCH FELLOW IN PATHOLOGY.

*(From the National Institute of Medical Research and the Ultra-Violet Clinic, Royal London Ophthalmic Hospital.)*

## PART I.*—ACTION ON THE OUTER EYE: PHOTOPHTHALMIA.

THE acute inflammatory reaction of the superficial parts of the eye to short-waved light, called photophthalmia by Parsons in 1913, has been known and recognised from very early times; Xenophon, in his Anabasis (iv., 5) mentions one of its forms—"snow-blindness." Its first mention in scientific literature seems to have been by Faucault in 1843, and from the medical point of view it would appear to have received its first adequate notice from Charcot, who, in 1858, detailed the distressing experience of two chemists, who, "after making some experiments on the fusion and vitrification of certain substances by the action of the electric battery . . . found in their eyes a feeling of severe irritation that evening and during the whole night, which they passed without sleep." After the general introduction of the electric arc for furnaces and lighting in 1879 the occurrence of the typical symptoms became quite recognised, and to-day they are probably to be met with most commonly as an accident among those who work clinically and experimentally with ultra-violet rays, or who are subjected to exposure to the short-circuiting of a high tension electric current, or any other source rich in short-waved light. The earlier writers, attaching much importance to the functional visual disturbances which usually accompany such exposures, attributed the inflammatory trouble to reflex or sympathetic influences from the retina (Terrier, 1888; Martin, 1888), but in his classical experimental researches in 1889 Widmark established the ætiology of the disease as we now recognise it, and, correlating the experimental and industrial troubles with those met with under natural conditions as in "snow-blindness," he showed that the common cause was the shorter ultra-violet waves.

### *Pathogenesis.*

The experimental production of photophthalmia has been studied amongst others by Birch-Hirschfeld, Parsons, Martin, and Verhoeff and Bell, whose findings have been largely confirmed by the writer, working under the direction of Leonard Hill.

The biological action of light upon the eye, as elsewhere in the body, varies with the wave-length; the longer waves, by increasing molecular movement, produce mainly a thermal effect, the shorter ones, whose frequencies correspond to the intra-molecular oscillations, by increasing atomic motion, produce molecular disintegration, with consequent photo-abiotic, photochemical, and photoelectrical changes. Unless radiant energy is absorbed it can exert no effect, pathological or otherwise, upon the substance through which it is passing; it is therefore with the light that is absorbed by the cornea that we are concerned.

The absorption of the cornea has been studied by a large number of investigators, whose results agree so closely that the matter may be considered as settled. The cornea, apart from radiations at the extreme end of the energy spectrum (electrical oscillations), completely absorbs heat waves longer than 20,000 Angström units; below this in the infra-red, part are absorbed and part are transmitted, the amount of the latter increasing until at 7500, just at the commencement of the visible reds, practically all are transmitted; thereafter, throughout the entire visible spectrum, it is almost completely transparent, the small amount of absorption which exists being determined largely by the lamellæ and the corpuscles causing internal reflections and refractions. This obtains down to the region of 3150 in the ultra-violet, when absorption again becomes considerable, the process becoming complete at about 2910. The lines of demarcation are not sharp, and the limits vary to some extent between individuals, and to a greater extent, and probably exponentially, with the intensity of the incident radiation, but for all practical purposes the lower limit of transmission may be taken as at 3000 A.U. Transparency again occurs at the extreme lower limit of the known spectrum, in the region of wave-lengths of the order of one A.U. (X rays, gamma rays). The absorption of the conjunctiva corresponds to that of the skin; all incident energy within the limits of the spectral range of ordinary sources is absorbed very rapidly, the abiotic rays being completely absorbed at a depth of about 0·1 mm., the heat effect of the luminous waves penetrating to the submucous tissues.

The rays producing symptoms of photophthalmia are the shorter ultra-violet. Theoretically energy of any wave-length should be able to produce some degree of abiotic action, but in living tissues any very slight and slowly produced changes that the longer waves may effect are either made good by the process of physiological repair or are masked by a preponderating thermal effect. A critical threshold both of wave-length and of intensity of radiation therefore exists. It has been established by the use of suitable filtering screens of graded degrees of transparency that the limiting wave-length which is able, in the intensities usually employed experimentally, to produce an inflammatory effect upon the cornea and conjunctiva is 3050 A.U. (Verhoeff and Bell). The effect in this region, however, is very small, and to cause any marked reaction radiation must be employed in considerable intensity and over a long period of time; *for all practical purposes it is the rays below 3000* which are responsible for exciting the condition, the most potent being those from 3000 to 2500. This corresponds with the limits of sensibility of the skin, as determined by Leonard Hill, Hausser, and others. Above this critical limit all the incident energy which is absorbed is converted into heat, producing when in quantity sufficient to cause pathological changes, a *thermal effect. This effect* as far as the cornea is concerned, on account of its great transparency, is practically negligible for all ordinary intensities of radiation throughout the visible spectrum, until we come to the infra-red.

Since the disturbance is the direct result of the absorption of energy, not only is there a critical wave-length, but there is also a very definite critical quantity of effective energy required to set up a reaction, and the knowledge of its magnitude is of importance in deciding the dosage appropriate for the local treatment of diseased conditions. In the rabbit an exposure of 2·5 minutes at a distance of 0·5 metres from a quartz mercury lamp (K.B.B., atmospheric pressure running at 200 volts, 3 amps.) is required to produce definite signs of conjunctivitis and stippling of the cornea; this represents a total abiotic energy incidence, expressed in biological units (Hill and Eidinow), of approximately 2 I.K. (infusoria killing) units, or about 2,000,000 erg-secs. per square centimetre. Allowing for slight variations due to individual idiosyncrasies—thus blonde people are usually more susceptible than dark—the human eye is more sensitive than that of the rabbit, a difference which may in part be due to the more ready elicitation of subjective symptoms. An average exposure under the same conditions of slightly less duration induces slight symptoms (i.e., a dose of approximately 2 I.K. units), which again corresponds with the minimum dose found by Hill and Eidinow to be necessary to produce the faintest appreciable erythema on the skin.

---

* Parts II. and III. will appear in subsequent issues.

The degree of reaction varies, moreover, with the intensity of the energy involved. Thus with a source of uniform intensity it varies, within limits, directly as the time of exposure, and inversely as the square of the distance of the radiating source from the eye. In this way an exposure of ten minutes under the above conditions produces a very marked conjunctivitis in rabbits, and after 15 minutes there is complete desquamation of the corneal epithelium, while the effects at 0·5 metre correspond in degree to those received in an exposure of four times the duration at 1 metre. Further, the effect of repeated exposures with intermissions is the same as their equivalent as a single long exposure, always provided that the time interval between them is not of duration so long that the factor of physiological repair comes into play. Up to 24 hours the effect of repeated exposures may thus be considered additive.

The relation to the intensity of energy is also seen in the site of the lesion on the cornea; in mild cases it is always central, in severe cases the greatest pathological changes are in the central region, and they progressively diminish in degree as the periphery is approached. This is due to the fact that the rays falling normally on the centre of the cornea are more concentrated that those falling slightly obliquely at the periphery, where the effect is therefore more spread out—the relation being comparable to the proportionate heat of the midday and evening sun. Further, some energy is always lost by reflection at the air-cornea surface, and the amount thus lost is a function of the angle of incidence, varying as its cosine (Lambert's law); the greater the angle of incidence—that is, the more obliquely the incident rays strike—the greater the loss by reflection, and the smaller the quantity absorbed. For these two reasons the intensity of absorbed energy per unit area diminishes progressively from the centre to the periphery, and the lesions are preferentially central.

### *Pathology.*

The pathological findings in a moderately marked lesion caused by ultra-violet light from a water-cooled mercury-vapour lamp as seen in the rabbit's eye are characteristic. There is a latent period usually of six to eight hours, which varies directly with the length and intensity of the exposure, during which no changes can be made out either macroscopically or microscopically. Thereafter in the slighter cases there is merely a stippling of the cornea with irregularity of its reflex and sometimes vesicular formation, accompanied by hyperæmia of the conjunctiva. After greater exposures the central corneal epithelium is desquamated and stains diffusely with fluorescin; still greater exposures leave a diffuse central interstitial haze, or a marked central opacity usually with sharply defined margins. The conjunctiva shows a considerable amount of inflammation with marked swelling and œdema, associated with a muco-purulent discharge. The changes are at their height in 48 hours, and thereafter gradually die down, the rate of recovery again varying directly with the intensity on the radiation. In three to five days after a moderately severe exposure the epithelium has reformed, and on clinical examination the eye appears normal. An opacity, if one has been formed, becomes highly vascularised in six to eight days, and tends to clear up to a surprising degree in four to six weeks, leaving a translucent interstitial haze.

A lesion due to the longer heat rays, on the other hand, is quite different. These were studied as produced by exposure to a bare carbon arc, the ultra-violet being screened off and the light at the same time being concentrated by a glass lens of 0·75 cm. thickness. This eliminates the greater part of the abiotic wave-lengths, and any pathological action is therefore a thermic effect. Here there is no latent period, discomfort is felt at once unless the cornea is cocainised, and both macroscopical and microscopical changes are induced immediately. There is no stippling of the cornea and no impairment of its surface or susceptibility to stain. In the whole of its thickness it looks sodden and cloudy, and an opacity forms almost immediately, while a conjunctivitis in much more marked degree than is the case under a corresponding abiotic radiation is very soon evident, accompanied by much chemosis and œdema and a frankly purulent discharge.

Histological examination also shows a typical picture. In the abiotic lesion, corresponding to the degree in which the rays are absorbed, the degree of pathological changes decrease in severity from without inwards through the thickness of the cornea, and gradually tails off towards the periphery. In the central region, 48 hours after moderate exposures, the surface epithelium is completely absent, and with it some of the more superficial corneal lamellæ have disappeared; more peripherally the outer epithelial layers only have exfoliated, leaving the basal cells spread out and spaced apart; further, towards the periphery the epithelium is normal. The lamellæ near the affected area are swollen and stain less readily with eosin, while the corpuscles show nuclear fragmentation and the cytoplasm becomes granular and eventually disappears, the entire cell disintegrating. There is massive eosinophile-celled infiltration—an appearance so evident as to be very striking. Descemet's membrane and the endothelium remain normal. Histological examination 10 to 15 days later shows no appreciable effects.

The conjunctiva shows histologically desquamation of the outer layers of the epithelial cells, while the basal cells are degenerated and spread out. There are small hæmorrhages, much congestion, and polymorphonuclear and plasma cell infiltration, and the subepithelial connective tissue shows hyaline degeneration. The secretion in the acute stage contains eosinophile cells.

The histological picture is quite different in a lesion due to the thermal action of visible and infra-red rays. The surface epithelium, cooled by contact with air, is intact, and, conversely to the abiotic reaction, the lesion increases in severity as the distance from the surface increases, the endothelium being completely destroyed in the central region. The corneal lamellæ are much swollen and have lost their structure in the central region, where the corpuscles are completely destroyed. The edges of the lesion are sharply defined, and are surrounded by an area of cell stimulation and proliferation, and in the periphery there is much leucocyte infiltration.

### *Clinical Symptoms.*

Photophthalmia, as it is met with clinically, is accompanied by a very characteristic symptomatology. There is always a latent period whose length varies with the intensity and duration of exposure; for ordinary exposures it lasts about six or eight to ten hours, and the unpleasant effects therefore usually start during the evening or night following. With extreme experimental intensities of exposures the latent period has been reduced to 30 minutes, and it would seem never to have exceeded 24 hours—the factor of physiological repair apparently counteracting the abiotic effects of radiation of intensity so weak as to necessitate a longer latent period than this. The first symptom is a sensation of slight pricking as of a foreign body in the eye, which in the mildest degrees of the trouble is all that may develop. After moderately intense radiation, as in the usual doses accidentally received, this is followed by considerable disturbance rapidly increasing to pain, accompanied by extremely marked photophobia, profuse lacrymation occurring often in crises, and blepharospasm, while an hour or two later ciliary neuralgia often develops. Meantime the eye becomes red and injected, exceptionally chemosis develops, and the pupillary reflexes are often delayed, while on the surrounding area of the skin of the face there is invariably some degree of erythema. On the whole, however, the objective signs lag behind the subjective symptoms. In the acute stage the cornea shows irregularity of its reflex, and if stained with fluorescin will be found to be stippled or to assume a diffuse slight central haze. The most distressing symptom is the blepharospasm, which, coming on as it usually does in the middle of the night, reduces the patient, as the writer knows from personal experience, to a peculiarly miserable and impotent condition. It is essentially a reflex protective mechanism, the lids closing tightly and involuntarily over the damaged cornea denuded of its epithelium and with its nerve terminals exposed, just as do the abdominal muscles over an inflamed peritoneum. The least attempt at movement, or the incidence of light increases this reflex spasm and brings on an acute paroxysm of pain, and to remain still under these conditions is no easy matter. For the ordinary exposures received accidentally the acute symptoms last from six to eight hours, and most of the discomfort has disappeared in 48 hours; with more severe exposures they may last for some days. A certain amount of injection and photophobia usually persists for some time, and if there is already present a chronic infection in the conjunctival sac it may, by superadding itself, keep up inflammatory symptoms of greater or less severity. After severe exposures some headache and slight visual disturbances may persist for weeks.

An actual thermal lesion is rarely met with under corresponding conditions, since, owing to the immediate response of the tissues to this portion of the energy spectrum, the discomfort will not be tolerated, and the eyes and head are turned away and thus protected. It does, however, frequently occur in momentary exposures to sources of sufficiently high intensity. Thus a lightning flash, or the flash of the short-circuiting of a high-tension current, contains a large proportion of infra-red rays, and if near enough will readily produce a "power burn," which is very often a heat effect, although an abiotic reaction is frequently present also. Symptoms come on immediately without any latent period, and the signs of external inflammation are much more marked than in the case of an abiotic reaction. There is great injection, chemosis, and almost always a frankly purulent conjunctivitis; it lasts in great severity for several hours, but, apart from any gross tissue damage that has been caused, the symptoms clear up more quickly than in the case of a lesion due to short-waved light. In the short-circuit flash the permanent tissue damage that may occur comprises haziness of the cornea (Rivers, Terrien, Lundsgaard), and an actual burn of the conjunctiva, usually accompanied by a similar burn on the face (Rivers, Terrien, Desbrière, and Bargy). Similarly, Silex, Vossius, Rivers, Dunbar Roy, and Le Roux and Renaud have noted corneal injury after a lightning flash. The energy involved in both of these is more than sufficient to exceed the threshold we have already seen to be necessary to produce an effect; thus that emitted from a short circuit involving 100 kilowatts is of the intensity order of $30 \times 10^6$ erg-secs. per square centimetre at 0·5 metre distance, and according to the estimate of Lodge the energy involved in a lightning discharge may be $10^{20}$ ergs. That such cases occur only rarely clinically is due to the fact that the discharge does not often occur sufficiently nearly and yet leave the individual free from actual electric effects, which mask the milder photophthalmic symptoms by causing lesions of a very much graver nature or even death.

### *The Occurrence of Photophthalmia.*

The typical course of an acute attack of photophthalmia as described above refers principally to the effects of exposures to the mercury-vapour lamp or a naked arc as it occurs, usually accidentally, in the laboratory or the clinic, but, within limits, it may be taken to apply to all similar conditions where short waves constitute the greater part of the radiated energy. Such exposures are fairly frequently incurred both industrially or under natural conditions.

(*a*) *Industrial Photophthalmia.*—Arc lamps have frequently given rise to photophthalmia, especially when they are being tested photometrically. A similar occurrence is met with in those exposed to the flash of a short circuit or to the emanations from molten metal in electric welding. In cinema studios a large quantity of photographically active light is necessary, and this is usually made up of two types: "soft lighting," which is obtained from "banks" of mercury-vapour lamps, and "hard lighting," derived from arcs used in searchlights. In this country in 1920 these were used unscreened, and the actors and actresses exposed to them suffered from alarming photophthalmic symptoms. Although no obvious trouble occurs when these are screened by glass, as they are always now, it is to be remembered that such a screen, while cutting off rays under 3000 A.U., transmits those above this, and the 3020 line in the mercury arc spectrum is of considerable intensity. While at the working distance this is not in intensity sufficient to cause photophthalmia, it is not improbable that with exposures lasting intermittently for years some more insidious damage might be caused in the inner eye, as will be considered in the later articles of this series.

(*b*) *Photophthalmia under Natural Conditions; Solar Photophthalmia.*—Owing to the absorption of ozone in the outer atmosphere the lower limit of solar radiation reaching the earth is 2910 A.U. Although the atmosphere appears to be more permeable to the shorter waves in extreme cold and the amount of the shorter waves penetrating it varies considerably, the percentage of rays between 3050 and 2910 is comparatively small and probably averages only 0·25 per cent. of the total solar energy (Abbot). Ordinarily, therefore, the sun-light does not produce symptoms of photophthalmia; when, however, the direct light is reinforced by a dazzling reflection in sufficient intensity from a surface of great extensity as the sea, the desert, or a snow-field, and an exposure of several hours to this doubled source is experienced, the critical threshold of abiotic energy may well be exceeded and symptoms of photophthalmia develop. The commonest form met with is that experienced after exposure to bright sun-light on a snow-field—usually called "snow-blindness—a thoroughly unsatisfactory term, since the photophthalmic symptoms are not caused by the snow but by the solar energy partly reflected from the snow, neither is there any blindness apart from dazzling and occasionally amblyopia and a central colour scotoma which may incidentally accompany the typical photophthalmic symptoms. A large literature has accumulated on the subject of solar photophthalmia, and its effects on mountaineers and explorers are well known, while the Eskimos suffer from it to a considerable extent (Daland). Neither are animals exempt, the polar bear *sometimes being a victim (Rossi). The trouble is* usually a mild one, and comes on after exposures lasting several hours. The typical symptoms already described are experienced after the usual latent period. In those living in these regions perpetually a chronic form is often encountered.

Although ordinarily the abiotic radiation present in the energy spectrum of the sun does not exceed the liminal threshold for producing pathological effects on the outer eye, cases have been reported of individuals who appear to have been abnormally sensitive—as, for example, that of a woman (Syme) who got an erythematous eruption on the face and injection of the eyes on every particularly bright day in summer. Such a reaction appears akin to the action of a sensitiser, and may be due to the presence of some substance of this nature in the blood of these people; it is, however, rare (compare hydroa æstivale).

### *Chronic Photophthalmia.*

A chronic form of photophthalmia was produced experimentally in rabbits by Birch-Hirschfeld, by exposing their eyes for ten minutes daily for 180 days to a mercury-vapour lamp. After the usual symptoms of acute photophthalmia had passed off the lesion which developed was a chronic mild conjunctivitis of the follicular type, the appearance of the conjunctiva, which was everted during the exposures, resembling very closely the typical picture of vernal catarrh.

Chronic photophthalmia of a somewhat similar nature is met with industrially (Behr) in welders and others who are frequently exposed to light sources emitting short-waved energy, and is usually accompanied by visual disturbances and an increased sensitiveness to light. The term usually applied to the condition—ophthalmia electrica chronica—is a misnomer, since electricity has nothing at all to do with the matter. The occurrence of solar photophthalmia in the chronic form has already been mentioned; it was first described as "keratitis solaris exfoliativa" by Kilkowe. Its occurrence is widespread wherever there is snow over a large part of the year; Gardner and Strader note it in America, Berlin and Enval in Scandinavia, Kilkowe and Gnonin in Central Europe, Reich in the Caucasus, Shomey in the Australian Alps, and Daland in Alaska, Siberia, and the Arctic Ocean. Infiltration and often ulceration of the cornea occur, resulting eventually in permanent impairment of the cornea with a band-shaped opacity running transversely, corresponding to the palpebral aperture as it is narrowed by approximation of the lids to avoid as much as possible the distressing glare from the snow. In all these places the natives have learned to protect themselves, some of the more primitive adopting correspondingly primitive devices; thus the Eskimos wear "glasses" made of a piece of wood or horn strapped round the head with a thong in which are cut two horizontal or vertical stenopœic slits opposite the eyes, through which the snow can be viewed with impunity, just in the same way as the sun is examined in eclipse with comfort through a pin-hole.

Owing to the similarity of the lesions produced experimentally by Birch-Hirschfeld to the appearance of the changes in the conjunctiva in vernal catarrh, the presence of eosinophile cells in both lesions, the fact that the incidence of this disease is limited largely to the hotter months of the year and the warmer countries, and its ready amelioration by bandaging the eyes, the hypothesis was advanced that it was a form of chronic photophthalmia due to short-waved light (Schiele, Kreibeich); and Junius suggests that its incidence may be determined by the presence of a sensitiser akin to hæmatoporphyrin in the blood. Vogt, on the other hand, suggested that the infra-red was the pathogenic factor. Although its ætiology has not yet been definitely cleared up, it is more than probably due to an infective agent; the resemblances mentioned are all superficial, and that it is certainly not due to ultra-violet light is seen in that it occurs almost exclusively underneath the upper lid, which cannot be reached by these rays in any circumstances, only very rarely on the lower lid, which might occasionally and with difficulty be reached, and almost never on the bulbar conjunctiva, to which these rays always have ready access.

### *Treatment.*

The treatment of photophthalmia is properly prophylactic; it is in the great majority of cases an accident or the result of carelessness in omitting to wear protective glasses on all occasions where exposure to short-waved radiations is possible. The fact of the liminal energy threshold has already been noted, and very short exposures to the sources in common use are therefore harmless, but it is to be remembered that short exposures are additive within a period of 24 hours. Widmark first showed in 1889 that the clinical symptoms were prevented by a plate of ordinary glass 0·5 cm. thick, and for exposures of ordinary intensity and short duration a pair of ordinary spectacles affords sufficient protection. With severe or prolonged exposures, however, it is found that ordinary glass will allow the transmission of waves capable of producing a violent reaction. This substance may be taken to absorb rays shorter than 3000 A.U., but we have seen that abiotic activity is obtained in the cornea up to 3050, and the 3020 line in the mercury-vapour spectrum is well marked. Moreover, for those continually exposed, the distressing glare is peculiarly trying without a considerable screening effect. A very large number of proprietary glasses have from time to time been put on the market to meet the case, most of them as commercial propositions, few of them with anything particular to recommend them. For purposes where it is wished to screen off the ultra-violet alone, Crookes' A glass is the most efficient. Where it is desirable that the visibles should be partly cut off, as usually applies to those conducting a clinic, or to those exposed to the glare from snow, &c., Crookes' B gives the best results, although ordinary smoked glass gives almost as much protection. None of these cut off the infra-red, and where these are to be excluded Crookes' sage-green glass eliminates 95 per cent., while as cutting off both ends of the spectrum, and toning down the luminous region, Pfund's gold-plated glass (American Optical Co.) is very effective and still permits of good illumination. This is made up of a very thin layer of prepared gold placed between a lens of ordinary crown glass and one of Crookes' A. The crown glass merely serves to protect the gold; the layer of gold reflects 98 per cent. of the infra-red and allows up to 75 per cent. of the luminous waves to pass, and the Crookes' glass absorbs the ultra-violet.

When once the attack has developed little can be done to reduce the distressing severity of the symptoms. Bromide and aspirin control the neuralgia, the former being well taken prophylactically after an accidental exposure. Cocaine in oil, locally administered as drops, reduces the corneal discomfort, and bandaging (not shading) the eyes, preferably with cold compresses, reduces the blepharospasm, especially if resorted to from the very beginning. Usually, however, this does not by any means relieve it and the accompanying paroxysmal pain; in such cases the most effective measure is to immerse the head in cold water, a procedure which gives great, though only temporary, relief.

# THE AFTER EFFECTS OF DIPHTHERIA ON THE HEART

BY JENNER HOSKIN, M.D. CAMB.,
ASSISTANT PHYSICIAN ROYAL FREE HOSPITAL.

IT has been recognised for many years that diphtheria has a serious effect on the neuro-muscular mechanism of the heart in a certain percentage of cases, and fatty degeneration of the heart muscle was described by Bristow as long ago as 1850. Other early investigators were Trousseau and Bretonneau, who noted the symptoms of those patients with diphtheria dying from heart failure.

In a report based on the diphtheritic cases admitted to the Philadelphia Hospital for Contagious Diseases during the summer of 1920, S. C. Smith[1] found that in 72 per cent. there were no cardiac complications, though the majority had tachycardia on admission, but in 28 per cent. vagaries of the pulse developed after several days, and in a few of these patients grave heart trouble succeeded. The initial tachycardia might last 36–48 hours only, but tended to persist for several days if myocarditis were present, and might end in heart block, which occurred suddenly on the seventh day. In 75 per cent. cases death took place in 36–48 hours. The block was usually complete, and its occurrence depended on the constitution of the patient, the length of time that had elapsed before antitoxin was given, the degree of toxicity of the disease, and the persistence of the tachycardia indicating the presence of myocarditis. Sinus arrhythmia was frequently found, and was considered by Smith to be physiological.

Premature beats occur in about 20 per cent. of the cardiac cases, more commonly arising in the auricles, and are of serious import if appearing in the first three weeks.[2] Auricular fibrillation is rare, though cases have been recorded by Parkinson[3] and Price[4] occurring in conjunction with heart block. Death may occur early, about the tenth day, from acute myocarditis, or later, about the third week, from fatty degeneration of the heart muscle.[5]

In a paper by F. W. White[6] based on 78 cases of diphtheria with heart complications, studied after discharge from hospital, he stated that most of the cases had murmurs with more or less cardiac enlargement. Sixty-five cases recovered completely during observation, of whom the majority cleared up in 2–4 months; 20 still showed signs after four months, and of these six cleared up in the following three months. In 13 cases the signs were persistent. In most cases there were no symptoms of heart trouble, but some were short of breath on exertion. He found, however, that the heart was often affected in the absence of symptoms as shown by enlargement, accompanied in 31 patients by a systolic murmur at the mitral area and by an accentuation of the second sound at the pulmonary area. This was due in most cases to dilatation and relative mitral incompetence. The murmurs were mainly over the mitral area, and were frequently transmitted into the axilla, increased by exercise, and accompanied by an accentuated pulmonary second sound. In a few cases these signs persisted, indicating pathological changes in the mitral valve.

In some of the older children systolic murmurs were heard over the base, altering with respiration and change of position; these tended to disappear as the patient improved, and were regarded as hæmic. Pulse irregularity was frequently seen, and also tachycardia. In the severer cases who had been kept in hospital 2–3 months, White found heart symptoms common, especially palpitation, weakness, pallor, and faintness after exertion, and occasionally cardiac distress in older children. The heart was dilated, mitral incompetence was present, the first sound at the apex was weak and sometimes reduplicated, the pulse was rapid and often irregular, and there was diminution of the cardiac reserve. The mild cases cleared up completely in the course of a few weeks, but the more severe took 5–6 months or more.

Other observers in the main agree with him, though Veronese[7] has found moderate hypertrophy only, and Baginsky[8] considers that chronic myocarditis or mitral regurgitation often persists for years without symptoms.

### *Clinical and Electrocardiographic Findings in 16 Cases*

My paper is based on 16 cases of diphtheria, which were sent to me for clinical and electrocardiographic examination on their discharge from the North-Eastern and North Western Fever Hospitals. All these cases had definite signs of heart involvement during their stay in hospital. Their ages varied from 3 to 19, the average age being just under 10 years. The length of stay in hospital averaged 80 days, the longest time being 140 days and the shortest 56. In none of the cases were cardiac abnormalities noticed during the first week of the disease, the earliest recorded being on the eighth day and the latest on the thirtieth. The mean time when the first signs were apparent was the eighteenth day.

The following were the principal abnormalities found whilst still in hospital:—

Tachycardia was present in all but one case.
Cardiac enlargement was found in three cases.
Alteration of the first sound at the apex was noted in seven cases, reduplication being present in four of them.
Reduplication of the second sound at the apex was found in two cases.
Premature beats were noted in two cases, and both occurred in the fourth week.

These cases were discharged from hospital under the normal procedure as convalescent. I found, however, that in none of them was the heart condition normal. The tachycardia had tended to persist and in nine out of the 16 cases the rate was over 100, the highest being 148 and the lowest 80. The mean rate was 107. Sinus arrhythmia was present in five cases, and premature beats arising in the auricles in one case. In three there was definite enlargement, but in one of these in which a mitral regurgitant murmur was present there was a suspicious history of past rheumatic trouble.

The heart sounds were altered in certain of the cases. In five cases the first apical sound was short, and in three reduplicated. In five the second pulmonary sound was accentuated and a gallop rhythm was found in two. A systolic murmur was present in 11 cases, mostly over the mitral area, usually faint, but tending to be increased by exertion. One case had developed paralysis of the right leg in the third week of the illness, and was still rather weak on that limb. Pallor was noted in two cases. In half the cases heart symptoms were complained of or found at the examination. These were mainly shortness of breath on slight exertion, undue fatigue, and faint feelings on moving about quickly. In all

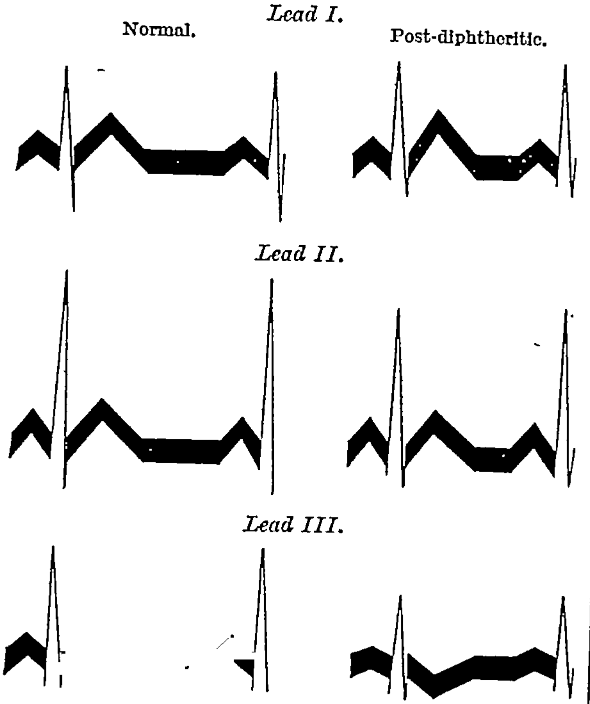
cases except one there was diminished cardiac reserve. This was more marked in those with tachycardia. I electrocardiographed every case, and also six children with normal hearts and of approximately the same ages in order to contrast the differences between the two series. The electrocardiographic differences between the post-diphtheritic cases and the "normals" are not of marked degree, the principal points of difference between them being the heart rate, 107 as against 84, and the increased negativity of the T wave in lead III. in the former. Other differences occurring in lead III. are the diminished amplitude of the R wave, 5·1 mm. as against 9·2, and the P wave 0·78 mm. as against 1·5. There was also slurring of the Q.R.S. complex present in all leads in five of the post-diphtheritic cases, slurring of the R wave in lead I. in one case, and of the R wave in lead II. in another. I found, however, no damage to the conductive system beyond the slurring already referred to, which is probably due to involvement of the terminal arborisations of the bundle of His in the muscle-fibres themselves.



The following are the mean electrocardiographic measurements between the "normals" and post-diphtheritic cases.

*Normals.*

| Lead. | P. | P.R. | R. | S. | Q. | Q.S. | T. | S.T. | Cycle. |
|---|---|---|---|---|---|---|---|---|---|
| I. | 1·5 | 0·14 | 7·3 | 3·6 | 0 | 0·05 | 3·3 | 0·27 | 0·71 |
| II. | 2·2 | 0·14 | 13·5 | 2·6 | 0 | 0·05 | 3·4 | 0·27 | |
| III. | 1·5 | 0·14 | 9·2 | 1·1 | 1·1 | 0·05 | 0·13 inv. | 0·27 | |

*Post-diphtheritic Cases.*

| Lead. | P. | P.R. | R. | S. | Q. | Q.S. | T. | S.T. | Cycle. |
|---|---|---|---|---|---|---|---|---|---|
| I. | 1·5 | 0·14 | 8·2 | 1·2 | 0·6 | 0·048 | 3·9 | 0·25 | 0·56 |
| II. | 2·14 | 0·14 | 12·2 | 1·2 | 0·4 | 0·048 | 3·0 | 0·25 | |
| III. | 0·78 | 0·14 | 5·1 | 1·5 | 1·1 | 0·048 | 1·8 inv. | 0·25 | |

The vertical measurements are in millimetres, and the horizontal in seconds. The tension of the fibre of the electrocardiograph is standardised so that a current of 3 millivolts will cause a deflection of 30 millimetres on the scale.

### *Summary.*

The 16 cases of my paper differ from normal children of the same age in the following respects: 1. The higher rate of the heart-beat. 2. The presence of cardiac symptoms in half the cases. 3. The diminished cardiac reserve. 4. The presence of heart abnormalities in almost all the cases. 5. The changes in the electrocardiogram, notably the presence of "slurring" of the Q.R.S. complex in five of the cases, and the alteration in the character of the third lead.

### *Conclusions.*

From my investigation of these cases, though I am afraid the numbers are very few, I think it is a fair assumption to make that the effect of the diphtheritic toxin on the heart, in those cases where it has become involved during the course of the disease, is a more lasting one than is generally recognised. It is therefore, in my opinion, of the utmost importance that patients, in whom cardiac symptoms and abnormalities have been discovered during their stay in hospital, shall be thoroughly examined, both clinically and electrocardiographically, on their discharge before being allowed to return to their ordinary avocations, and that if the heart is found to be still affected they should be kept under observation until it has either regained the normal or has reached a stationary condition of recovery.

I should like to express my gratitude to Dr. F. H. Thomson, superintendent of the North-Eastern Fever Hospital, Tottenham, to Dr. E. W. Goodall, superintendent of the North-Western Fever Hospital, Hampstead, for their kindness in sending these cases to me, and to Dr. Ursula Blackwell, medical officer at the North-Eastern Fever Hospital, to whom I am indebted for the selection and hospital records of most of the cases.

# THE NATURE OF THE DEPRESSOR SUBSTANCE OR SUBSTANCES IN TISSUE EXTRACTS.*

BY SWALE VINCENT, D.Sc., M.D. LOND., F.R.S. EDIN. AND CANADA;

AND

F. R. CURTIS, M.Sc., M.B., CH.B. LEEDS.

(*From the Physiological Laboratory, Middlesex Hospital Medical School.*)

THE history of the subject may be told very briefly. In 1900 Osborne and Vincent[1] showed that extracts of nervous tissues cause a fall in blood pressure which is obtained after section of both vagi and after full doses of atropine. On the same date there appeared a communication by Halliburton[2] in which similar results were announced, with the important difference that neither nervous tissue extracts nor choline gave a fall after atropine. According to Osborne and Vincent, then, choline could not be entirely responsible for the depressor effect.†

In 1903 it was shown by Vincent and Sheen[3] that the depressor effect is not peculiar to extracts of nervous tissues, but is common to all the tissues of the body with the exception of the adrenal and the infundibular part of the pituitary. They found that, just as in the case of nervous tissues, extracts of other organs must contain some active principle which is not choline. The general statement that all animal tissues impart to watery or saline extracts a substance or substances which, when injected into the circulation of a living animal, lower the arterial blood pressure was made in the first edition of "Internal Secretion and the Ductless Glands" published in 1912. About this time, too, the suggestion arose that the active substance might be histamine.

---

* The expenses involved in this research have been defrayed by a grant to one of us (S. V.) from the Government Grant Committee of the Royal Society.

† Schäfer and Moore[4] had incidentally noted a fall of blood pressure as the result of injection of brain extracts, and Mott and Halliburton[5] had suggested that the active substance was choline.

That these facts were well known has not hindered numerous sporadic communications to the effect that some tissue or other contains an active principle which lowers the blood pressure. It is necessary only to mention a few examples. In 1918 Marfori found that lymphatic glands contain a depressor principle, and quite recently McDonald,[4] and James, Laughton, and Macallum[5] have reported that there is a depressor substance in extracts of liver.

Attempts to isolate the active principle have not been very numerous. Vincent and Cramer[6] found that there are two groups of substances in watery extracts of nervous tissues, both of which, when injected into the veins of an animal, lower the blood pressure. Both are soluble in water and in saline, while one group only is soluble in alcohol. The alcoholic solution contains two depressor substances, one of them has its effect abolished by atropine, the other has not. Evidence was found of the presence of choline in the form of a di choline anhydride, but it was abundantly clear that the depressor effect of nervous tissue extracts is not due entirely, nor even largely, to the presence of this choline derivative.

Owing to the appearance of numerous pharmacological papers on the action of histamine, the claim of this substance to be considered as responsible for the depressor effect has been more or less revived, but its position has always been weak, because it is insoluble in ether, while the depressor substance (or substances) is soluble in this medium.

A not unnatural suggestion—namely, that the lowering of blood pressure is due to a mixture of choline and histamine in the extracts—has quite recently been made by Best, Dale, Dudley and Thorpe.[7] On referring to the papers of Osborne and Vincent and Vincent and Sheen, it will be seen that tracings are shown in which the depressor effect of tissue extracts is clearly indicated before and after atropine in all three laboratory animals—dogs, cats, and rabbits. These, as recently pointed out to us by Prof. R. J. S. McDowall, show clearly that histamine cannot be concerned in the effect, as this substance does not produce a depressor effect in rabbits, except under special conditions which need not be referred to here.

We have repeated and extended the experiments upon rabbits and find that before the administration of atropine, choline produces a fall; histamine either no effect or a rise, a mixture of choline and histamine, a very slight fall usually combined with a slight rise, tissue extracts a pronounced fall. After atropine choline produces a marked rise; histamine either no effect or a rise, a mixture of choline and histamine a slight but pure rise; tissue extracts a pronounced fall. Thus we have abundant evidence that, although choline and histamine may be present in tissue extracts, and may be partly responsible for their physiological activity, there must also be present some other substance which differs fundamentally in its pharmaco-dynamical action and presumably, therefore, in its chemical nature, from either of these substances.

There is some evidence that choline plays a larger part in the actions of nervous tissue extracts than in those of extracts of other organs and tissues, though even in the former it is clear that a large part of the effect is due to some substance which is neither histamine nor choline.

## ROYAL SOCIETY OF MEDICINE

### SECTION OF LARYNGOLOGY

THE summer meeting of this Section took place on June 3rd and 4th, under the Presidency of Dr. W. H. KELSON, the first session being devoted to the reading and discussion of papers.

Sir WILLIAM WILLCOX read a paper on

*Nasal Sinusitis as a Cause of Toxaemia.*

His object was to show how frequent was the rôle played by nasal sinus disease in conditions of illness, the causation of which was obscure, looking at the subject from the standpoint of the general physician. He maintained that in most cases, if one was alive to the possibility, some focus of infection could be found. Sometimes X rays showed a shadow when transillumination did not reveal any striking differences, and in this connexion he said he thought the radiologist should restrict himself to stating what he found, leaving the interpretation to others. For instance, to report that there were certain abnormal dark areas was within the radiologist's province, but the declaration that pus was present might launch the physician into a sea of uncertainty. Sir William Willcox emphasised the importance of sinus examination in all cases of chronic ill health. Each patient presented a problem in immunity, and the management of every case should be based on that view, and operative measures should be restricted as much as was consistent with the best interests of the patient, who should be given every chance to recover from the auto-intoxication. He showed several patients and recounted their histories, which definitely supported his contentions.

Sir STCLAIR THOMSON said transillumination was of value only in comparing one side with the other. The only certainty in the matter of diagnosis was afforded by exploration, and he was glad Sir William Willcox had put forward the plea that the radiologist should cease from diagnosing sinus trouble, not only because he had not the evidence to enable him to do so, but his declaration sometimes placed the physician in an awkward position with his patient, who knew the opinion which had been given. Sir StClair Thomson showed charts of cases in support of Sir William Willcox's paper.

Mr. HERBERT TILLEY agreed that if an antrum was dark on transillumination it did not necessarily mean it was the seat of active disease.

Dr. P. WATSON WILLIAMS agreed with the advice to seek for a focus of infection in cases of obscure illness, and not to wait until there was clear evidence of infection. Pancreatic disease was sometimes due to a chronic infective condition, often associated with chronic cholecystitis.

Dr. W. SYME said there had long been a tendency to deal too leniently with suppuration in the accessory sinuses, both in regard to diagnosis and treatment. Transillumination might lead to error in many cases of antral disease; the only method was to examine the contents of the antral cavity derived by puncturing it.

Sir JAMES DUNDAS-GRANT spoke of osteo arthritis which probably originated in sinus disease, and said he had seen nervous and despondent people restored to health and cheerfulness after the ethmoid cells had been cleaned out. He advocated a greater use of transillumination by the general practitioner.

Dr. A. LOGAN TURNER read a joint paper, by himself and Dr. F. E. REYNOLDS, on

*A Fatal Case of Leptomeningitis.*

This was a case in which the death of the patient followed an operation on the ethmoidal air cells, and Dr. Turner showed, by means of an admirable series of slides from the case, the path which the infection took. He submitted the contribution because the case clearly showed that one possible path of infection between the nose and the intracranial structures was via the lymphatic channel. The patient, a man aged 33, had suffered from nasal obstruction due to polypi on both sides. These were removed and the ethmoidal cells exenterated. Following this, a temperature of 103·8° F. quickly developed and pneumococcus was grown from the turbid cerebro-spinal fluid. Death took place five days after the operation.

Dr. W. JOBSON HORNE gave a short contribution, supported by an epidiascopic demonstration, on the

### *Rôle of the Lymphatics in Laryngeal Disease.*

Twenty-five years ago, he said, it occurred to him that the lymphatic supply of the larynx was an open field for research, and since then, as the material arrived, he had been following the subject up. First he dealt with cases in which there was established disease in the larynx, and the lymphatics became involved subsequently. It was strange that there were very few diseases of the larynx in which the adjacent and corresponding cervical glands became implicated. One notable exception to this was malignant disease of the larynx. In this, sooner or later, the glands became involved, and the period at which that occurred depended largely on whether the cancer was extrinsic or intrinsic. In the case of the latter, the date of gland involvement depended on whether the part of the larynx attacked was covered by squamous epithelium or by columnar epithelium, it being earlier in the latter than in the former, and the results of interference in these cases was less satisfactory. As to the rôle of the larynx in lymphatic disease, he showed sections from cases of Hodgkin's disease and of mediastinal sarcoma in which the larynx became involved. He said that some sarcomata seemed to be remarkably benign, and some authorities considered that they should be classified with the granulomata. He did not claim that the condition of the larynx was responsible for Hodgkin's disease, but it was one site of infection, and the particular vulnerable site was between the cartilages of Santorini and Wrisberg.

The second session was devoted to clinical cases. In the evening the Section entertained Sir StClair Thomson, the President of the Society and a prominent member of the Section, to dinner.

## EDINBURGH OBSTETRICAL SOCIETY.

AT a meeting of this Society held on May 12th Dr. R. W. JOHNSTONE, the President, being in the chair, Dr. F. J. BROWNE described a case of

### *Concealed Hæmorrhage with Placenta Prævia.*

The patient, he said, was a primigravida who had completed eight months of her pregnancy and was admitted to hospital on account of vaginal bleeding. Placenta prævia was diagnosed and the vagina was packed. Twelve hours later the pack was removed and external version attempted, but was not persevered with on account of the large amount of old blood-clot that was passed. The membranes were therefore ruptured and spontaneous delivery took place three hours later. The placenta was normal in appearance and size, but overlying it was a quantity of fairly old blood-clot, which covered practically the entire portion which had been prævia and extended into the upper portion as well. The clot weighed over 12 oz. A catheter specimen of urine contained a moderate quantity of albumin. Three other cases described by Holland, Williamson, and Swayne were discussed, after which Dr. Browne stated that none were cases of purely unavoidable hæmorrhage, and his own case showed that in some cases of placenta prævia the hæmorrhage might be concealed; the concealed hæmorrhage, however, might be due to mechanical separation of the portion of the placenta situated in the lower uterine segment and in this event would be unavoidable. Placenta prævia could not be excluded in a case of concealed hæmorrhage, and some cases of concealed hæmorrhage without albuminuria might be accounted for in that way. In all cases described, however, albuminuria was present and, therefore, it was justifiable to presume the bleeding to be of toxæmic origin; thus bleeding in placenta prævia might sometimes be accidental.

Dr. W. F. THEODORE HAULTAIN spoke on

### *Some Practical Aspects of Antenatal Care,*

the great importance of such care to mother, child, doctor, and the State being pointed out. Dr. Haultain disagreed with the relative frequency of the vertex positions as stated in the leading text-books on the subject. From statistics of 1000 cases seen within 14 days of labour at the antenatal clinic of the Simpson Memorial and Royal Maternity Hospital, Edinburgh, and another 1000 uncomplicated full-term cases delivered in the labour ward of the same hospital, the relative frequency in round figures was found to be L.O.A. 60 per cent., R.O.A. 30 per cent., R.O.P. 8 per cent., L.O.P. 2 per cent. The figures for primiparæ and multiparæ were taken separately in each case, but little variation was shown in these two main groups.

*Relative Frequency of Vertex Positions.*

| — | Primiparæ cases. | | Multiparæ cases. | | Total cases. | |
|---|---|---|---|---|---|---|
| | Ante-natal, 453. | At labour, 477. | Ante-natal, 548. | At labour, 523. | Ante-natal, 1000. | At labour, 1000. |
| | % | % | % | % | % | % |
| L.O.A. | 56·4 | 63·7 | 55·5 | 66·9 | 55·9 | 65·4 |
| R.O.A. | 32·3 | 27·0 | 34·5 | 25·3 | 33·4 | 26·1 |
| R.O.P. | 8·0 | 8·4 | 7·1 | 5·9 | 7·5 | 7·1 |
| L.O.P. | 3·3 | 0·9 | 3·1 | 1·9 | 3·2 | 1·4 |

The efficacy of pads as described by Buist in posterior cases was then discussed, and statistics were given of 70 consecutive occipito-posterior cases which had been treated at the antenatal clinic during the last two years; 38 of these were primigravidæ, and in these the pads proved successful in 33 by substituting an anterior position for the posterior; in multiparæ 25 were successful, thus in the whole 70 cases success was obtained in 82·8 per cent. In every case success or failure was judged by the position at labour as well as that found in the clinic after removal of the pads. To achieve success it was stated that (1) the treatment should not be done till the last month of pregnancy, (2) the head must be movable, and (3) castor oil should be taken at night when the pads were in position. No danger could be caused by the treatment to either mother or child, and the difficulty of the future labour could not be aggravated by the treatment, which was very simple and would in many cases avoid a tedious and often dangerous labour.

The statistics of a consecutive series of cases of external version in breech presentations was then given. In all 28 cases had been so treated in the last one and a half years, 12 in primiparæ and 16 in multiparæ. Among the primiparæ version was successful on nine occasions and among the multiparæ 14 successes were reported; thus 82 per cent. of the total number were successful. Anæsthesia was recommended to aid success in primigravidæ and the manipulation was not advised till the last month of pregnancy. Failure in the primigravidæ was attributed to the cases being of the "frank breech" variety, the failure in each case being noted at the time of manipulation, whereas in the multiparæ the two failures were caused by a return of the breech presentation after it had been turned. The technique for the measurement of the diagonal conjugate was described; this measurement should not be taken more than six weeks before full term, for by that time the perineum and soft parts were soft and the promontory of the sacrum could be reached in most cases with comparative ease, whereas earlier in pregnancy it was usually a very difficult procedure. By the estimation at this period there would be still plenty of time to decide on induction of premature labour if required, and if the pelvis was too small to warrant induction at that time then the case was one for Cæsarean section and not induction With regard to the position of the patient to allow this measurement to be taken with the greatest ease, Dr Haultain advised the exaggerated left lateral position, the woman flexing herself as much as possible. Extreme gentleness in making the estimation was necessary to obtain satisfactory results

In conclusion, Dr Haultain thought that antenatal care did not begin early enough, and suggested that patients should be seen after having missed one period; by that means a large number of abortions might be averted, especially those due to a retro displacement of the uterus, the bowels could be looked after, and all cases of slight sickness could be treated, thus might hyperemesis gravidarum be practically obliterated Rarer conditions such as tubal gestation could also be recognised before rupture occurred and the woman's life put in danger

## ROYAL ACADEMY OF MEDICINE IN IRELAND

### SECTION OF MEDICINE

A MEETING of this Section was held on May 14th, Dr F C. PURSER, the President, being in the chair

Dr R STUMPF read a paper on

*Rontgen Therapy in Connexion with Certain Blood Diseases*

Having reviewed the treatment of polycythæmia rubra vera, pernicious anæmia and lymphatic leukæmia, he considered the subject of myelogenous leukæmia in greater detail. In his opinion, the best treatment was by X rays combined with the administration of arsenic There was never complete cure, but cases were known in which improvement sustained over many years had resulted from X ray treatment of this condition Relapses occurred in weeks or months, each responding, but ever more slowly, to treatment. After each treatment there was a diminution in the size of the spleen, a drop in the leucocyte count, and an improvement in the patient's general condition The focus for radiation was the spleen The essential point to remember was that each case must be treated on its individual merits and no dogmatic scheme could be followed The aim was to improve the patient's general health rather than to attain a rapid diminution in the size of the spleen and an immediate drop in the number of leucocytes As regards technique, it was best to start with small doses and increase them very carefully Dr Stumpf gave an acount of a case of myelogenous leukæmia Mrs B, aged 28, showed for several months atypical symptoms and suddenly developed a severe pain in her abdomen about a year ago The spleen was found to be much enlarged and the leucocyte count was 250 000 per c.mm She had had three courses of X ray treatment, and during part of the time was getting injections of arsenic In the course of treatment the leucocytes gradually fell from 250 000 to 25,000 per c.mm This favourable figure had not been maintained, since it was not considered necessary to give sufficient exposures to the X rays to bring about this result, the patient's general health being excellent Frequent blood counts were being carried out and sufficient treatment was given to maintain the leucocytes somewhere between 60,000 and 90,000 per c.mm At the beginning of treatment the spleen reached to below the level of the umbilicus and extended across the middle line It was now three fingers breadth below the costal margin and was well to the left of the middle line The patient's weight had increased very considerably and her general condition was excellent

Dr A. R PARSONS said that his results had been much the same as Dr Stumpf's as regards early improvement and subsequent failure to repeat the first success. He asked whether deep X ray therapy had any advantage over ordinary X rays

Dr MAURICE HAYES said that with deep X rays the number of treatments were less, the intervals between treatments were longer, and the risk of damaging the skin less, also by deep X rays it was possible to get a more uniform radiation at the first dose

Dr J SPEARES wondered if X ray treatment did in reality prolong the life of these cases As to lymphatic leukæmia, it was his experience that the patient might live a very long time He was at present treating a patient who had had the disease for 21 years

Sir JOHN MOORE read a Historical Note on Alkaptonuria, recalling the first example of this abnormality described in Dublin, at a meeting over which the speaker presided 45 years ago

*Exhibition of Radiograms*

Dr J SPEARES and Dr G BEWLEY showed radiograms of three cases of diaphragmatic hernia One of Dr Speares's cases had marked gastric symptoms for relief of which operation was urged Dr Bewley's case was one of eventration

Dr C L McDONOGH showed radiograms of (*a*) rickets with multiple fractures, (*b*) sarcoma of the sternum. In the former case eight fractures of long bones were to be seen, the changes typical for rickets being marked in the long bones, ribs, and skull In the latter case the X ray appearance of the tumour, the failure to find any primary growth, and the negative W R. pointed to the very rare condition of primary osteo-sarcoma of the sternum.

Dr T GARRETT HARDMAN and Dr LEONARD ABRAHAMSON showed radiograms of a chest after injection of lipiodol, and gave an account of the technique employed

### SECTION OF ANATOMY AND PHYSIOLOGY

A MEETING of this Section was held on April 16th, Dr C M WEST, the President, being in the chair

Prof J M O CONNOR demonstrated Indian ink injections of the living kidney blood vessels, and read a paper on

*The Blood Flow through the Kidney and its Relation to the Theory of Urine Formation*

He said that by diverting the blood of the left kidney down the vena cava into a reservoir while the blood pressure is maintained by a reserve of blood in a compensation tube connected with the aorta, the blood flow through the kidney at constant arterial pressure could be examined On closing off the compensation tube the flow with falling pressure could be determined If the blood flow were graphed against the prevailing pressures there was, with falling pressures, a kink (or kinks) in the graph in the sense of increases or decreases in the blood flow These kinks occurred at various levels of blood pressure and of blood flow, and were relatively the same at all levels in any one animal. A similar kink could be produced by diminishing the pressure in the renal artery by a clamp on the abdominal aorta, while the pressure was maintained constant in the rest of the body by having a carotid artery connected with the compensation tube Similar alterations in flow either positive or negative resulted from the injection of diuretics These results were in keeping with the suggestion that the flow of blood through the kidney is regulated by a compression of the glomeruli by the secretion pressure of the urine Experiments in which the kidney vessels were injected with Indian ink showed agreement with the theory that the relative number of glomeruli uninjected or but partly injected corresponded with the kink on the graph of blood pressure and blood flow

The PRESIDENT said that until he had heard Prof O Connor's paper he had not been aware of any opening of the glomeruli and he did not see why even when destruction of the capsule occurred, it should block up the vessels of the glomeruli. Referring to the injection and non-injection of glomeruli, he asked if Prof. O'Connor allowed the injection to flow for any length of time first, and to go on flowing till the kidney got black; or if the injection just flowed through the kidney vein. He himself did not see why the blood should flow through every vessel of the kidney at the same time.

Dr. W. A. TAYLOR asked if Prof. O'Connor had ever tried experiments to determine the amount of blood flow through the kidney in a given time, and had tried to determine from this the relation between the time of the blood flow and the amount of the blood flow through the kidney. He believed the blood flow through the kidney was very great.

Dr. F. H. MOORE asked if Prof. O'Connor had found the urine altered in any way after he had carried out his experiments; if, for example, when the vessels were clamped and the blood flow altered, there was any albumin in the urine. He mentioned the work of Oscar Clotts, of Montreal, in relation to the altered circulation of the blood in a nephritic kidney to that in an ordinary kidney. Oscar Clotts said that in nephritis one was dealing with an organ altogether different from a healthy kidney. He himself believed that rabbits suffered from chronic interstitial nephritis in their old age, and he wondered if the study of these animals would throw any additional light on Prof. O'Connor's theory, especially in relation to nephritis.

Dr. L. G. GUNN asked if, when Prof. O'Connor was experimenting on one kidney, the second kidney was left alone. Sometimes the secretion of one kidney stopped altogether for a time, but then the other kidney acted very vigorously. After nephrectomy it was quite common for patients to get attacks of polyuria without any apparent reason.

Prof. O'CONNOR, in reply, said that the kidney was almost stony hard, and this hardness varied accordingly to the activity of the kidney. If the kidney was secreting well it was especially hard. When an injection was given it always came out through the renal vein. The blood flow through the kidney was enormous. The maximum flow in a rabbit's kidney was 6 c.cm. of blood per minute. Cutting the kidney nerves caused vaso-constriction which gradually passed off; but sometimes the constriction was so great that no urine flowed for a considerable time. The second kidney was practically always left alone. It was commonly thought that the more urine was passed the better the kidney was working, but from his experiments he did not think it was so. He believed that as often as not, when the flow was small, the kidney was doing just as much work as when the flow was big.

# GENERAL MEDICAL COUNCIL.

### TUESDAY, JUNE 1ST.

### PENAL CASES.

IN accordance with the usual custom the penal cases were heard in public, the Council deliberated on them in camera, and the results were then announced.

The Registrar read a report by the Dental Board of the United Kingdom on *the case of William Birkett*, registered on June 21st, 1922, as of 189, East India Dock-road, Poplar, London, E. 14, who had appeared before the Board in November last, charged with employing an agent to canvass for him; also for certifying to the Royal Liver Friendly Society the delivery of certain dentures and receiving fee for the same when, in fact, no dentures had been supplied to the patient. The Board found certain facts satisfactorily established and considered that Mr. Birkett's name ought to be erased from the Register. The Council directed that it be erased.

*The Case of John Edward Rees* (adjourned from May, 1925).—This practitioner, registered as of 10, Priory-street, Carmarthen, L.R.C.P. Edin., 1913, L.R.C.S. Edin., 1913, L.R.F.P.S. Glasg., 1913, had been convicted of drunkenness on five separate occasions, three times when in charge of a motor vehicle, and judgment had been postponed for one year. Mr. Rees appeared, accompanied by his counsel, Mr. Daniel Johns, instructed by Mr. J. C. Williams, solicitor, of Carmarthen. Counsel read several letters in regard to Mr. Rees's good character since the previous hearing. The Council decided not to erase his name from the Register.

*The Case of Henry James Burke, M.C.*, registered as of Ivy House, Hadfield, Derbyshire, L., L.M., 1913, R.C.P. Irel., L., L.M., 1913, R.C.S. Irel. This practitioner had appeared before the Council in May, 1925, having been convicted at the Glossop police-court and Mottram Petty Sessions on three occasions of being drunk in charge of a motor-car. Judgment had been postponed for 12 months. Mr. Burke appeared in answer to his notice and gave an assurance that he would abstain from alcohol. Having considered evidence with regard to his conduct during the last 12 months the Council decided not to erase his name from the Register.

*The Case of Austin Heron*, registered as of West African Medical Service, L., L.M., 1924, R.C.P. Irel., L., L.M., 1924, R.C.S. Irel., had also been adjourned from the session of May, 1925. He was then charged with having been convicted, under the name of William Gallagher, at the Sutton Petty Sessions of insulting behaviour to certain females. Mr. Heron wrote from West Africa asking for the postponement of the Council's decision for another year, when he would be able to attend in person. The Council agreed to the further postponement.

### WEDNESDAY, JUNE 2ND.

*The Case of Andrew George Tottenham Hanks*, registered as of 10, Edith-grove, Chelsea, London, S.W. 10, L., L.M., 1888, R.C.P. Irel., L., L.M., 1888, R.C.S. Irel., who appeared before the Council in November last, having been convicted in London police-courts on four occasions of being drunk and incapable. Mr. Hanks was accompanied by his solicitor, Mr. Oswald Hempson, who handed in letters in regard to his good conduct in the interval. The Council decided not to erase his name from the Register.

*The Case of Abdallah Jacob Dowek*, registered as of 265, High-street, Pendleton, Salford, Lancs, L.M.S.S.A. Lond., 1925, who had been summoned to appear before the Council on the charge of seeking to promote his own professional advantage by inviting patients of Dr. Arthur Clouston Russell, whose assistant he had previously been, to become patients of his. The complainants were the London and Counties Medical Protection Society. Dr. Dowek attended, accompanied by Mr. Jackson, K.C., instructed by Messrs. Barrow-Sicree, solicitors. The complainants were represented by Mr. Dickens, K.C., instructed by Messrs. Le Brasseur and Oakley, solicitors. Dr. H. B. Brackenbury, a member of the London and Counties Medical Protection Society, took no part in the proceedings. Mr. Dickens examined Dr. Russell, who testified that while he was in hospital during the summer and autumn of 1925 his wife had engaged Dr. Dowek as his assistant. Dr. Dowek, when Dr. Russell came out of hospital and requested him to sign the usual bond, had refused to do so unless it contained conditions of his own providing for increased pay and his engagement as permanent assistant with a view to partnership. Dr. Russell, after giving Dr. Dowek two days to reconsider his refusal, had dismissed him with no further notice. Dr. Russell had then heard rumours that Dr. Dowek had set up in practice near by and had been trying to attract certain of Dr. Russell's patients to himself; he had therefore instructed one Chapman, whom he employed as his collector, to find out further details. As a result of the information Chapman gave him he had complained to his defence society. A statutory declaration by Chapman was before the court, in which statement he admitted having misled Dr Russell Mr Dickens called various patients of Dr Russell s in evidence, some of whom testified that Dr Dowek had called on them, inquired how they were and had told them that he was now in practice on his own At the conclusion of the case for the complainants Mr Jackson submitted that on the evidence before the Council there was no case for the accused practitioner to answer The Council, after deliberation, dismissed the case

*The Case of William Joseph Ryan*—This practitioner's name was erased on charges of drunkenness, but leave was given to apply after an interval for restitution.

WEDNESDAY, THURSDAY, AND FRIDAY, JUNE 2ND, 3RD, AND 4TH

*The Case of Samuel Grahame Connor*, registered as of 119, Oxford-street, London, W 1, M B , C M , 1899 U Edin *Dr Connor appeared before the* Council on the following three counts (1) of affording to certain drug addicts facilities for obtaining dangerous drugs in the form of prescriptions, by which they were enabled to obtain from chemists morphine and heroin, such prescriptions not having been given in the ordinary course of bona fide medical practice and treatment , (2) of supplying morphine, which he had obtained for his own surgery use, to certain addicts otherwise than in the course of bona fide medical practice and treatment , and (3) of having been convicted at Marlborough-street police-court on March 29th, 1926 on each of three summonses for an offence against No 9 of the Regulations made under the Dangerous Drugs Act, 1920—viz., of failing to enter in a register, kept for the sole purpose, 50 gr of morphine purchased and obtained by him—and having been sentenced to two months' imprisonment in the second division for each of the three offences, and also fined £50 for each Also of having been convicted at the same time of an offence against No 5 of the said Regulations—viz., of giving a prescription for the supply of morphine and failing in that prescription to specify the address of the person for whom it was given—and having been fined £50 On appeal to the County of London Sessions the sentences *of imprisonment* were remitted and the fines ordered to stand.

The complainants were the Home Office, who were represented by Sir Travers Humphreys , counsel instructed by the Director of Public Prosecutions Dr Connor was accompanied by Mr J A Hawke K C , M.P , and Mr H D Roome, instructed by Messrs Engall and Crane, solicitors

Sir Travers Humphreys in opening the case for the prosecution, submitted a principle governing the correct use of dangerous drugs He suggested that their use was only admissible in certain circumstances. One was in attempting to cure an illness another was in attempting to cure an addiction by administering diminishing doses and the third was their use in minimum quantities to enable incurable addicts to live useful lives If a medical man became a mere purveyor of drugs to anyone who asked for them he was abusing the great trust reposed in him by the State In any case the essence of the proper use of dangerous drugs was strict personal supervision The case against Dr Connor, he said, was as follows: On May 28th 1923 Dr Crosse, a Divisional Medical Officer of the Ministry of Health, was sent to interview Dr Connor about certain drug addicts. Dr Connor had then told him that to give the drugs they required was the only way to get rid of some addicts who made a great deal of trouble Dr Crosse disagreed, and pointed out the necessity for refraining from giving dangerous drugs except to persons who could be strictly supervised Dr Connor agreed and thanked Dr Crosse confirming his agreement with these views almost immediately in a letter Counsel now read a list of prescriptions given by Dr Connor to a Mrs. V D down to the time of the interview with Dr Crosse, in which he prescribed about 40 gr at a time The day after this visit Dr Connor prescribed 10 gr , and thereafter progressively reduced the doses until March, 1924, when they again began to increase By September, when she ceased to be a patient, she was getting 40 gr a month Miss P , another patient, had landed, said counsel, at Oban on June 17th, evidently ill, and had sent Dr Connor a telegram containing the words " Please send, very important." The Home Office had sent Dr Crosse to Dr Connor with a copy of this telegram, which had been intercepted, and Dr Connor gave him some *particulars of the patient's history* She was then said to have been Dr Connor's patient for about four years, and he told Dr Crosse that she had been in a nursing home for phthisis and had first been given heroin by another doctor The prescriptions registered by the chemist showed that this lady had received several amounts of four or five grains, sometimes on two consecutive days , he had continued to treat her after this and had prescribed steadily increasing amounts of heroin. Following an interview by an inspector of police in December, Dr Connor had reduced these amounts, and in February Miss P answered an advertisement of a lady doctor, Dr Vivian, inviting resident cases. She was anxious to be cured if possible Dr Vivian had reduced her doses from a grain and a quarter a day to a tenth of a grain, and would say that she could have cured the patient if she had stayed long enough However after about five weeks a friend took her away Dr Vivian had found that Miss P s condition did not justify her receiving heroin

Miss B , another addict, had been receiving very small doses of morphine and atropine from her regular medical attendant and had been introduced to Dr Connor for the sole purpose of obtaining morphine Whereas she had been getting only 92 gr a year, Dr Connor had given her 14½ gr *on the first day and in* ten months had supplied her with 700 gr On March 29th 1926 two local practitioners, Dr Dillon Kelly and Dr Moon, had been called in to Miss B for severe asthma and had decided that she was assuming the symptoms in order to get morphine Dr Moon had put her in Lambeth Hospital, where Dr A. L. Baly had attended her Dr Baly had seen no reason to give her morphine and with the exception *of a quarter of a grain on the night of her admission*, had given her no more up to the present. It was for omitting the address on one of Miss B s prescriptions that Dr Connor had been fined.

Colonel S. G, had crashed during the war and injured his spine Dr Connor had been supplying him with enormous amounts of morphine , 100, and once 200 gr at a time, either by prescription or in bottle Finding it difficult to get morphine in Paris, where he lived, he paid periodical visits to Dr Connor to obtain his supplies.

Miss Y , over whom the magistrate had sentenced Dr Connor to imprisonment, was an old and quite incurable morphine addict She had lived for years in Glasgow On May 24th, 1924 a police officer visited Dr Connor and told him that Miss Y had been convicted of forging prescriptions to get morphine and was being attended by a doctor in Glasgow, who was prescribing this drug In 1925 Dr Connor had been writing orders to a chemist for quantities of morphine for surgery use, 50 gr at a time, and posting the bottles off himself to Miss Y , the result being that in no chemist's register was there any indication that she was getting any morphine at all In December 1925, Dr Connor told Inspector Burnby that Miss Y had been to see him about six times that year and that he had sent other prescriptions to her in Glasgow From the list of prescriptions it appeared that she had only come four times and that Dr Connor had been supplying her by other means. She had had 850 gr in 1925 When the officer asked for Dr Connor s accounts and methods of requesting payment, Dr Connor replied that he never rendered accounts and that his patients paid exactly what they chose. He said that on Dec. 11th the lady had sent him a money order for £8 for eight visits at about a guinea a time

Of Dr. Connor's three convictions one was for failing to register quantities and names of recipients, and 850 gr. of morphine were unaccounted for. In his cross-examination at the quarter sessions Dr. Connor had said that he got the chemist to send to Miss Y. the morphine which he had ordered for surgery use in order to save her chemist's fees. Counsel submitted that this was no explanation. Further, Dr. Connor had admitted both that he knew that Miss Y. was being attended by a doctor in Glasgow and that she had been convicted for forging prescriptions.

Counsel then called Dr. R. E. Crosse, Divisional Police Surgeon, and examined him as a witness. Dr. Crosse said that he had called on Dr. Connor on May 28th, 1923, with a list of names of persons alleged to be addicts. Dr. Connor had said that, as he did not dispense, he did not keep a register. He admitted prescribing morphine and heroin as snuff to avert serious consequences and to prevent patients becoming troublesome. He had agreed that there was little possibility of success unless strict supervision were maintained, and undertook to decline to prescribe for patients whom he could not supervise. He had written a letter confirming this. On August 6th, 1925, he had gone to see Dr. Connor about a telegram from Miss P. which the Home Office had intercepted. Dr. Connor had told him that Miss P. had been his patient for about four years and had been taking heroin to relieve a cough; she had been in a nursing home and had been cured of the heroin habit. Dr. Connor had not given him the name of the home nor that of the medical attendant. Miss P. had then, according to Dr. Connor, gone on a voyage to South Africa and had there succumbed again to the habit; he was now supplying the drug solely by reason of her addiction, and did not hope to cure her. In addition to other amounts he had prescribed 5 gr. on June 16th and 4 gr. on June 17th, also he had prescribed 4 gr. on July 4th and another 4 gr. on the 5th. Dr. Connor said that she had had 12 gr. on June 6th as she was starting for the Hebrides; he could not explain how he had come to prescribe on the two consecutive days, June 16th and 17th. He could not remember having received a telegram nor having despatched a prescription in response.

Mr. Hawke cross-examined.

Counsel then called Dr. M. C. Vivian, who said that Miss P. had come to her as a resident patient, in answer to a standing advertisement, on March 31st of this year, to be cured of the heroin habit, and had stayed till May 6th. Witness had reduced her in five weeks from 1½ gr. a day to 1/10 gr. She had tried other drugs as substitutes without success. Another fortnight, she thought, would have produced a total cure. Nothing in Miss P.'s physical condition, except her addiction, had justified her receiving heroin. During the time Miss P. was with her she had written to Dr. Connor asking him not to send her any prescriptions or drugs; she had received no reply. Cross-examined, the witness said that Miss P. had left while she was out and had given no notice. In answer to a question from the President, witness said she had written to Dr. Connor because Miss P. had told her that he had been prescribing and she was afraid that the patient would continue to receive prescriptions.

Counsel then called Dr. A. L. Baly, assistant superintendent of Lambeth Hospital, who said that Miss B. had been admitted on March 31st of this year. He had not seen her until the morning after she arrived. She had been in a very agitated state and had told him that she was suffering from asthma that could only be relieved by morphine. She had had a quarter of a grain on admission. Although she had been admitted on the representation of the relieving officer under the Lunacy Act, she was not certifiably insane. She was still in the hospital and had had no more morphine, as he had not considered it necessary. Her health had considerably improved. Cross-examined, he admitted that it was a remarkable thing that depriving her of morphine had been so successful. Replying to a question from the President, he said that she was showing signs of bronchitis. He had known that she had been taking morphine and had seen a copy of a prescription for two-thirds of a grain twice daily. He had given her a dose of sterile water, which had had the required effect; he had often known this happen.

Counsel then called Detective-Inspector W. Burnby, who said that he had interviewed Dr. Connor on several occasions. He deposed that he had taken with him several originals and copies of prescriptions, including those made out for Miss Y., all of which, with one exception, were ordered for surgery use. Miss Y. had been convicted on August 24th, 1922, for forging a prescription for morphine; she had been released to a home and admonished by the sheriff. He had told Dr. Connor that she was being treated by another doctor in Glasgow. The doctor had said that he saw her once a month when she came and stayed at an hotel in London. He had told Dr. Connor that she had been convicted for forgery. Dr. Connor had said that he would not have treated her if he had known that she was being treated by another doctor. The doctor had said, when he interviewed him on Dec. 24th, 1925, that Miss Y. spent considerable time in London, as she was a rich woman and had property at Tottenham, and that he knew she was being treated by another doctor and was writing to her about it. He had said that he had kept no accounts for two years and that his charges were one guinea per visit, and that on Dec. 11th he had received a money order from Miss Y. for £8 at the rate of one guinea per visit. The officer said that he had inspected the register of the chemist who had been supplying the doctor and had found that, out of 13 orders that he had fulfilled, only one was to the prescription of Dr. Connor. The doctor had told him from his books that he had received 575 gr., but the chemist's register showed over 800. The doctor had explained that he must have made a mistake; that the morphine had been obtained for surgery use, and some of it had gone to Colonel S. G. Cross-examined as to whether he had used the exact term "register" in questioning Dr. Connor, witness maintained that he had. He knew Miss Y. by repute and believed that she throve on morphine and carried out her business well. He denied that he had stated in the criminal proceedings that Dr. Connor had been the ruin of one man.

The President pointed out that qualified medical practitioners were exempted from keeping a register if they kept a book in addition to a day-book.

Replying to the question of a member, through the chair, witness said that he understood that the charge of one guinea was for visits only, and that patients had to pay separately for drugs.

Counsel then called Dr. C. F. Dillon-Kelly, who stated that on the evening of March 29th this year he was called to see a patient, Miss B., in place of Dr. Moon, who practised near by. The patient's relatives had asked him to give her an injection of morphine as she was in a very excited state. She was putting on symptoms of bronchial asthma to an extent which, in his opinion, amounted to malingering. After talking to her for about a quarter of an hour he did not think fit to administer morphine, and Dr. Moon had later agreed with him. He had given her an order for admission to the Maudsley Hospital, but next day she had gone to the Lambeth Infirmary. Cross-examined, witness admitted that the patient showed some genuine signs of asthma and, in reply to a question from the President, stated that they were not as severe as they looked.

This closed the case for the prosecution.

Mr. Hawke then addressed the Council, setting forth the lines of the defence. Commenting on the principle laid down by Sir Travers Humphreys, he remarked that it raised the questions (1) of what a minimum dose was in the case of a confirmed addict, and (2) who was to be the judge of this minimum. He submitted that only a medical man could be permitted to decide these points and that no official idea, even of those who were performing the valuable service of combating a real evil, could be allowed to determine them. He considered also that there were certain considerations of which this principle did not take account—e.g., that addiction is in itself a disease. This view was confirmed in the report of the Select Committee of inquiry, who asserted that it might be necessary to administer dangerous drugs to confirmed addicts in non-diminishing doses in order to enable them to live normal and useful lives. Apart from this there were cases of people who, on account of some injury, lived in continuous agony, and it was surely permissible to administer drugs to these in mercy. In addition to relying on this principle, said Mr. Hawke, Sir Travers Humphreys had suggested an interpretation for certain facts which put a sinister construction on the conduct of Dr. Connor and implied that he was not influenced by medical instincts but by rapacity. In general contradiction to this view he had put into court a testimonial signed by many eminent and trustworthy people affirming the integrity of Dr. Connor. Nor had his client any financial reasons for rapacity. Many general practitioners treated drug addicts, but these formed a very minute percentage of their practices. Dr. Connor saw 400 patients a month; in fact, in February he had seen 521, and of these only five were drug addicts. The proportion averaged about 1 per cent. Again he could recall a police-court case against a drug addict for forgery, in support of which charge Dr. Connor had been called as a witness. The magistrate had actually placed the prisoner in Dr. Connor's hands for treatment, and Dr. Connor had looked after him for some time and had reported to the magistrate weekly. He did not hold up Dr. Connor as a man of very methodical habits of book-keeping. Nevertheless the whole bulk of the Home Office's information which had been used as evidence had actually been supplied by Dr. Connor himself, with the exception of the telegram. As regards the morphine that he had ordered for surgery use, his books showed when he had it and what he did with it. If Dr. Crosse had understood Dr. Connor to say that he would rather get rid of drug addicts by giving them prescriptions than attempt to cure them, then Dr. Connor repudiated the suggestion entirely.

In the case of Miss P., when Dr. Connor said that he had no record of having received a telegram from Scotland he was telling the truth. Dr. Connor had a great number of patients and it was quite reasonable that he should have forgotten it, and there was no evidence that he was seeking to conceal anything. These things had taken place many years ago. In fact, he had actually told Dr. Crosse that he had prescribed for this lady on the very day the telegram was said to have been sent, and the prescription appeared on the list which he had furnished to Dr. Crosse from his records. Dr. Connor had been prescribing for Miss P. 5 gr. every four or five days and this, in his judgment, was the right dose for her. He had allowed her 80 gr. at one time to take with her to Scotland. In answer to the question whether he had really made any effort to cure this patient, he had actually advised her to go into a nursing home and she had gone. Later on she had re-acquired the habit in South Africa and had come back taking as much cocaine and heroin as she could get hold of. He had re-started her with the dose that he thought proper, about 3 gr. a day, and from March to May had reduced her to about 1 gr. to 1¼ gr. a day, at which amount she had settled down. She had then gone to Dr. Vivian's home, and this doctor had reduced her to 1/10th of a grain a day. Dr. Vivian had said that another fortnight would have cured Miss P. The departmental report, however, stated that the most difficult part of the treatment was the reduction from the last ¼ gr. to zero. The significance of this was that when Miss P. was reduced to 1/10th of a grain she had bolted. He suggested that Dr. Connor had done all he could.

Of Miss B. he would only say that she was already taking morphine for asthma and that Dr. Connor had prescribed the amount he thought fit. The paucity of this amount had actually reduced Miss B. to such a state that she had had to be sent to hospital under the Lunacy Act.

As for Miss Y., every dose she had had was recorded in Dr. Connor's books, and, since these employed medical formulæ, it was natural that the police officer should not have been able to understand them. Dr. Connor had given him every assistance and had gone over them with him in detail. Miss Y., according to her own story given in the police-court, had been an addict for 20 years, and Dr. Connor had supplied her with amounts which might seem considerable. But she was an exceptional woman and, although she consumed even more morphine than Dr. Connor gave her, she was healthy-looking and freshly-coloured, and conducted her own business. Inspector Burnby had said that she throve on it. This was obviously a case of a confirmed addict receiving a minimum dose to enable her to lead a useful life.

Counsel did not know how the case of the Colonel fitted into Sir Travers Humphreys's principle. His spine had been crushed and he was suffering excruciating agony; presumably it was forbidden to give him morphine as no attempt was being made to cure him. Dr. Connor could say that he knew of an operation which would relieve the agony while leaving the patient permanently paralysed. Meanwhile he was administering the drug in order to relieve this agony. Counsel submitted that he was perfectly entitled to do so in the interests of humanity.

The case of Mrs. D. showed a definite attempt on the part of Dr. Connor to cure her addiction by diminishing doses. In December, 1922, when he had begun to treat her, she had been receiving 120 gr. of snuff in 18 days. By June 23rd, 1923, she was down to 48 gr. a month; in July she had received 34 gr. and in August 28 gr. Thereafter her average was 35 gr. per month. In 1924 she had left London for the North of England, and Dr. Connor had refused her request that he should continue to treat her except on condition that she remained under his personal supervision. Dr. Connor could bring evidence of cases of apparent addiction which he had apparently cured and who had not returned to him.

In regard to the police-court convictions Dr. Connor had been fined because out of a large number of prescriptions for Miss B. he had omitted the address from one. The other convictions were for failing to enter morphine in a special register. He was not a regular dispenser, and the properly qualified medical man was exempt from keeping such a register if he kept a day-book and any kind of a note-book to show what he did with his drugs. The Chairman of Quarter Sessions, in considering the appeal, had been satisfied that the utmost of which Dr. Connor had been guilty was gross carelessness, and the fines had been the utmost which could be imposed for inadvertence.

Counsel then called Dr. Connor on his own behalf, and Mr. Roome examined him. Dr. Connor testified that he had been 35 years in practice and four years at his present address, also that the proportion of his drug addicts to his other patients was less than 1 per cent.

Miss P. had come to him suffering from phthisis and had been accustomed to drugs before he knew her. He had treated her for symptoms as they arose. She had gone into a nursing home on his suggestion to be treated for the heroin habit, and had been cured. When she had come out of the home she had gone on a voyage to South Africa, but, since she had been able to obtain unlimited supplies of cocaine and heroin out there, she had come back as bad as ever. He had cut off her cocaine and had reduced her heroin gradually to 1¼ gr. a day. Below this he had not succeeded in keeping her. In his opinion his treatment of her was correct. His plan had been to get her down as far as he possibly could and then send her to a nursing home. He had made no concealment in his books of the drugs he had been giving her and had written a prescription in every case.

Miss B. had been suffering from asthma and was accustomed to taking morphine. She had not told him that another doctor had been prescribing for her. He had done his best to reduce her doses, but it had been a continual struggle. He had been genuinely trying to treat her addiction.

In Miss Y.'s case every supply, other than by direct prescription, had been in accordance with his books. Miss Y. was his wife's personal friend and visited them, and he had considered that she was under sufficient supervision. Sometimes, instead of sending her a prescription, he had given the chemist an order and asked him to post the bottle off; he had never sent her any himself. This was for Miss Y.'s convenience. When she ran short she became very excited, and it was bad for a drug addict to be subjected to worry.

The President asked the witness in what form he had given these orders to the chemist. The witness replied that sometimes he had ordered it in Miss Y.'s name and that on some occasions he had told the chemist to send it direct to her and had put it down as for surgery use. In every case he had made a record in his day-book.

Continuing his replies to examination, the witness said that Colonel S. G. had had his spine crushed and lived in continual agony. He had supplied him with large amounts at a time because he had found it difficult to get supplies in Paris, where he lived. It was impossible to cure him altogether. The witness had tried several drugs and morphia was the only one that had been any use.

He had reduced Mrs. D. to about 35 gr. a month; in 1924 she had left London for good and he had declined to continue treating her, as he had thought he could not look after her properly. He said that he had succeeded in curing four cases of addiction out of 12 in two years. He had never meant to suggest to Dr. Crosse that he gave addicts a drug in order to get rid of them.

In reply to cross-examination by Sir Travers Humphreys, witness maintained the truth of all he had said and denied any intention to conceal his supplies of morphine to Miss Y., also that he had known she had been convicted for forgery and was being treated by another doctor in Glasgow.

After the Council had deliberated in camera for an hour and a quarter the President announced the decision as follows:—

Mr. Samuel Grahame Connor, I have to inform you that the Council have given careful and prolonged consideration to the three paragraphs of the charge brought against you. The first and second charges are that under the circumstances set out you have prescribed or supplied dangerous drugs otherwise than in the course of bona-fide medical practice; the Council have not found these charges proved to their satisfaction.

The third charge is with regard to your convictions on three summonses under the Dangerous Drugs Act; these convictions have been proved to the satisfaction of the Council. Having regard to the judgment in the court of appeal, they have decided not to proceed to direct the erasure of your name from the Medical Register in respect of these convictions, but to postpone judgment on the question for one year, expecting you in the interval to obtain evidence from persons of position in the profession and otherwise as to your character, conduct, and methods of medical practice during that time, and on the proper request from the Registrar to supply the names of such persons who are ready to testify. You will be required to come before the Council this time next year on a date which will be notified to you, and to satisfy the Council on the points I have mentioned.

This, I think, is the first case brought before the Council on a conviction under the Dangerous Drugs Act, but they have already issued a warning notice that not only convictions but contraventions which have not been the subject of convictions may be dealt with by the Council as offences which render a registered medical practitioner liable to have his name erased. I will read the warning notice which, I take it, you have already received, but which I desire to read in public for the information of the profession.
